Born at Fischbach, Germany, June 17, 1837. Died at Mobile, Ala., March 6, 1910. Joined the American Pharmaceutical Association and became a life member in 1896. Served as First Vice-President 1904-1905, and as Second Vice-President 1879-1880, and was elected Honorary President in 1907.
WILLIAM MARTIN SEARBY

Born in England, January 21, 1835. Died at San Francisco, Cal., October 7, 1909. Joined the American Pharmaceutical Association in 1882. Was elected President in 1907, and served as First Vice-President 1901-1902, as Second Vice-President 1889-1890, and as Chairman of the Council 1908-1909.
PROCEEDINGS

OF THE

AMERICAN

PHARMACEUTICAL ASSOCIATION

AT THE

FIFTY-EIGHTH ANNUAL MEETING

HELD AT

RICHMOND, VA., MAY, 1910.

ALSO THE

CONSTITUTION, BY-LAWS AND ROLL OF MEMBERS.

Baltimore:

Published by the American Pharmaceutical Association.

1910.
OFFICERS OF THE ASSOCIATION.

1910-1911.

PRESIDENT.
EUGENE G. EBERLE ................ Dallas, Tex.

FIRST VICE-PRESIDENT.
WM. B. DAY ....................... Chicago, Ill.

SECOND VICE-PRESIDENT.
OTTO F. CLAUS ..................... St. Louis, Mo.

THIRD VICE-PRESIDENT.
LEONARD A. SELTZER ............... Detroit, Mich.

TREASURER.
HENRY M. WHELPLEY ................ St. Louis, Mo.

GENERAL SECRETARY.
CHAS. CASPARI, Jr. ................. Baltimore, Md.

REPORTER ON THE PROGRESS OF PHARMACY.
C. LEWIS DIEHL .................... Louisville, Ky.

EDITOR OF THE BULLETIN.

LOCAL SECRETARY.
C. HERBERT PACKARD ............... Boston, Mass. (iii)
In accordance with the requirements of Chapter I of the By-Laws, an election for four officers of the Association and three members of the Council, for the year 1911–1912, was held by mail during the months of August and September, 1910, and as shown by the report of the Board of Canvassers, hereto attached, the following candidates have received a plurality of the votes cast and are therefore declared elected, the installation to take place at the next annual meeting at Boston, Mass., in August, 1911:

President—John G. Godding, of Boston, Mass.
First Vice-President—Wilhelm Bodemann, of Chicago, Ill.
Second Vice-President—Chas. M. Ford, of Denver, Colo.
Third Vice-President—Ernest Berger, of Tampa, Fla.
Members of the Council—Eugene G. Eberle, of Dallas, Tex.; James M. Good, of St. Louis, Mo.; George F. Payne, of Atlanta, Ga.

CHAS. CASPARI, JR., General Secretary.

Charles Caspari, Jr., General Secretary.

Having been appointed by President E. G. Eberle to act as a Board of Canvassers to examine and count the ballots cast for officers of the A. Ph. A. and members of the Council for 1911–1912, we the undersigned have the honor to submit below a tabulated record showing the result of the canvass of said ballots.

The total number of ballots received was 1002. Of this number one was a written ballot and six of the regular ballots were entirely unmarked; your Committee, therefore, deemed it proper not to include these seven ballots in the count, nor would they have made any material difference in the result had they been counted.

SUMMARY OF BALLOTS COUNTED.

THE FUNDS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

At the San Francisco meeting in 1889, the Permanent Secretary was directed to publish annually, in the Proceedings, a brief history of the origin, money value, and use to which each Fund may be applied.

There are five permanent Funds at the present time (July 1, 1910), three of which are invested in Massachusetts State bonds, in the name of the Treasurer of the American Pharmaceutical Association.

THE LIFE MEMBERSHIP FUND.

The Constitution, as originally adopted in 1852, and up to the year 1856, contained no provision for life membership or for the creation of a permanent fund. In the year named a revised Constitution was reported by a committee, and, after consideration, adopted (see Proceedings 1856, pp. 12, 14, 27 and 79). Article II., Section 7 (afterwards Section 8), containing the following provision:

"Members who have paid their annual contribution for ten successive years shall be considered life members, and exempt from their yearly payments, and entitled to a certificate to that effect."

Owing to increased expenditures for the publication of the Proceedings, etc., the Association found it necessary in 1867 (Proceedings, p. 75) to increase its revenue, one of the measures being the erasing of Section 8, and the total abandonment of life membership in the future.

In 1870 a revised Constitution was adopted (See Proceedings 1870, pp. 87–96), and this, with a few slight amendments adopted in 1896 and 1900, is in force at the present time, containing the following:

"Article IV. All moneys received from life membership, together with such funds as may be bequeathed, or otherwise donated to the Association, shall be invested by the Treasurer in United States Government or State securities, the interest of which for any current year only may be used by the Association for its expenses."

Chapter VI., Article 5, of the By-Laws adopted the same year, reads as follows:

"Any member who shall pay to the Treasurer the sum of seventy-five dollars at a time shall become a life member, and shall be exempt from all future annual contributions."

This article was amended in 1888 and 1896 and again in 1906 and changed to Article IV., Chapter VIII. As now in force, it reads as follows:

"Any member of the Association who shall pay to the Treasurer the sum of $100.00 during the first year of his connection therewith, and also any member not in arrears, who after ten years shall pay the sum of $75.00, or after fifteen years the sum of $50.00, or after twenty years the sum of $25.00, and any member who may have paid annual dues for thirty-seven consecutive years, shall become a life member, and shall be exempt from all future annual contributions."

In the roll of members for the year 1872 (page 338) the name of the late Charles W. Badger, of Newark, N. J., appears for the first time as a life member, and the only one (until the time of his death in 1877) under this provision, which was subsequently modi-
fied (Proceedings 1879, page 799) so as to reduce the sum to be paid into the treasury by those who had been members for five to twenty years. In the same year the published roll contained the names of two new life members. The article on life membership was further modified in 1888 (Proceedings, page 52), again in 1896 (Proceedings, page 17), and again in 1906 (Proceedings, page 100), so as to apply to those who have been members for over twenty years (see Chapter VIII, Article IV, of the By-Laws). Under this clause the life membership (new style) of the present roll is ninety-eight, as published in the Proceedings.

The Treasurer’s report for 1880 (page 524) states the life membership fund to be $75, for 1881 (p. 513) $613, for 1882 (p. 608) $685, for 1883 (p. 436) $904.38, and for 1884 (p. 524) $944.14. At the Milwaukee meeting, held in the same year, the Association directed (Proceedings, p. 525) that $316, which amount had been in past years donated to the funds of the Association by various members, be withdrawn from the general fund and be added to the Life Membership Fund. At the Providence meeting in 1886 (Proceedings, p. 147) it was recommended by the Finance Committee, and approved by the Council and by the Association, that the sum of $3,000 be transferred from the general fund to the Life Membership Fund. At the Cincinnati meeting in 1887 (Proceedings, p. 471) the Association ordered again a transfer to the same fund of $4,000.

Since 1887 the annual reports of the Chairman of the Council give the number of each bond of the registered securities in which the Life Membership Fund is invested. By vote of the Association, the name of this fund was changed to the William Procter Jr. Fund on September 15, 1902 (see Proceedings 1902, p. 214), but was changed back to its original name, Life Membership Fund, on September 5, 1906 (see Proceedings 1906, p. 100). The report of the Treasurer on the special funds of the Association, contained in the addendum to his annual report (see page 479 of this volume), shows that on July 1, 1910, the value of the Life Membership Fund was $17,319.85 (face value of securities only given), of which sum the interest for any current year only may be used by the Association for its expenses.

THE EBERT PRIZE FUND.

At the Richmond meeting in 1873 (Proceedings, p. 58), Mr. Albert E. Ebert presented to the Association the sum of five hundred dollars, to be used in the following manner:

“The money to be properly invested by order of the Executive Committee, and the annual interest derived therefrom to be appropriated for conferring a suitable prize for the best essay or written contribution containing an original investigation of a medicinal substance, determining new properties, or containing other meritorious contributions to knowledge; or for improved methods of determined merit, for the preparation of chemical or pharmacal products; the prize to be awarded by a suitable committee within six months after the annual meeting at which the essays are presented for competition; provided, that in case no one of the essays offered is of sufficient merit to justify the award, in the judgment of the Committee on Prize Essays, all may be rejected, and the sum added to that of the Fund.”

The offer was accepted by the Association, and by a special vote (Ibid., page 70) the fund was ordered to be called the Ebert Fund, and the prize awarded from the proceeds to be known as the Ebert Prize.

The Ebert Prize was awarded for the year 1874 to Chas. L. Mitchell; for 1877, to Fred. B. Power; for 1882 to John U. Lloyd; for 1886, to Emlen Painter; for 1887, to Edward Kremers; for 1888, to Jos. F. Geisler; for 1890, to Wm. T. Wenzell; for 1891, to John U. Lloyd; for 1897, to Albert B. Prescott and Jas. W. T. Knox; for 1898, to Virgil Coblentz; for 1899, to Henry Kraemer; for 1900, to Edward Kremers and Oswald...
The Ebert Fund amounted in 1883 (Proceedings, p. 436) to $683.43. Since 1887 the reports of the Chairman of the Council specify the securities in which this fund is invested. On July 1st, 1910 (Proceedings, p. 477), its reported value was $927.12 (face value of securities only given). The annual interest must be applied to a prize for an original investigation meeting the requirements stated above.

In accordance with the recommendation of the committee on invested, savings and trust funds, submitted and adopted at the fifty-eighth annual meeting, see Proceedings, 1910, p. 454, the name of the Ebert Fund was changed to Ebert Prize Fund, and the amount of the prize limited to $25.00 until the excess of interest above the sum annually awarded and added to the principal shall amount to $1,000.00, after which the entire annual interest upon the same shall constitute the Ebert Prize.

THE CENTENNIAL FUND.

After the meeting held in Philadelphia in 1876, the local committees, on settling all accounts for the entertainment of the Association, had an unexpended balance left, which by subsequent collections made in Philadelphia was increased to $5.25. At the Toronto meeting in 1877 (Proceedings, p. 481), Dr. A. W. Miller, local secretary for 1876, presented this sum in the name of the local committees, to the Association, with this condition, "that a like amount be subscribed by the members within one year," with a view of establishing a fund to aid in the prosecution of original investigations, the interest accruing from the investment of the fund to be devoted to the defraying of expenses actually incurred by members in conducting investigations in some branch of science connected with pharmacy. The Association accepted the conditions (Ibid., pp. 526–528), and adopted the name Centennial Fund.

The collection of a like amount by the Association was completed at the Saratoga meeting (Proceedings 1880, p. 553), when $582.81 had thus been received. In the following year a committee of the Centennial Fund was provided for in the By-Laws of the Council, Chapter VII (Proceedings 1881, pp. 190, 549). Members have not availed themselves of this fund to the extent contemplated at its foundation; for the amounts paid out have been only $7.50 to Rott. B. Warder for material used for investigations reported in 1885; $96.80 used by the Committee on National Formulary during the years 1886 and 1887 (Proceedings 1889, page 16); and $32 to Edward Kremers for material necessary for the prosecution of scientific research on the menthol group, reported in the Proceedings for 1892; $50 to the same investigator in 1893, and $50 again to the same investigator in 1894. In 1896 the sum of $22.33 was paid to the Committee on Indicators for material used in their investigations.

The original sum of $1107.81 ($5.25 + $582.81) had increased in 1883 to $1232.76. Since 1887 the securities in which the fund is invested are specified in the reports of the Chairman of the Council; the reported value was $2413.67 (face value of securities only given) on July 1, 1910 (see Proceedings, p. 477). The interest accruing from this Fund is to be used for defraying the expenses incurred in conducting original investigations in pharmacy or an allied science.

THE ENDOWMENT FUND.

At the fifty-fourth annual meeting, held at Indianapolis, Ind., September. 1906, Messrs. Samuel A. D. Sheppard and James H. Beal proposed the establishment of a permanent
fund to be known as the "Endowment Fund" (see Proc. 1906, p. 99), under the following conditions:

"That the said S. A. D. Sheppard and J. H. Beal jointly agree to pay into said fund one dollar for each twenty dollars contributed and paid into said fund by all other members of this Association up to and until such Endowment Fund shall, with its accumulations of interest, reach the sum of twenty-five thousand dollars ($25,000).

"That as moneys shall be received as additions to said fund the same shall be invested in such securities as the Council may direct until the interest and other accumulations, together with the amount of the principal, shall reach the sum of twenty-five thousand dollars ($25,000).

"That when the Endowment Fund shall have reached the sum of twenty-five thousand dollars ($25,000) one-half the income derived therefrom may be used for any purpose deemed wise by the Association.

"That when said Endowment Fund, inclusive of donations, interest and other accumulations, shall amount to the sum of fifty thousand dollars ($50,000), the Association may use ninety per cent. of the income therefrom for any purpose deemed wise by the Association.

"That under no circumstances whatever shall all the income from said fund be used, but at least ten per cent. thereof shall be annually added to the principal of the Endowment Fund.

"That under no circumstances whatever shall the principal or any part thereof be used for any purpose except investment for income, nor pledged for any debt of obligation of the Association, or any person, nor used for any other purpose or in any other manner than as specified."

Contributions to the Endowment Fund have been made at different times, and the names of the contributors published in the annual volume of Proceedings (see Proc. 1907, pp. 47 and 48; Proc. 1908, pp. 476 and 477; Proc. 1909, p. 464; Proc. 1910, p. 478); according to the Treasurer's report, the total amount contributed up to July 1, 1910, was $5,049.70.

THE GENERAL FUND.

On February 26, 1909, the Council directed that $5,000.00 of the current funds of the Association be invested by the Treasurer in some interest-bearing security, to be approved by the Finance Committee and the Chairman of the Council (see Proc. 1909, p. 449). In accordance with this order the Treasurer reported on May 26, 1909, having purchased five $1,000.00 St. Louis, Mo., 4 per cent. bonds at 103 5/8 and accrued interest. Again on November 15, 1909, the treasurer, in accordance with an order of the Council (see motion No. 11, page 449), invested $5,000.00 of the current funds of the Association in St. Louis city public buildings and public works 4 per cent. gold bonds. All of these bonds are registered in the name of the treasurer of the A. Ph. A. and are kept in the Association's safe deposit box.

THE WM. PROCTOR, JR., MONUMENT FUND.

At the fifty-second annual meeting held at Kansas City, Mo., September, 1904, it was resolved to solicit subscriptions for a memorial monument to be erected in the Smithsonian Grounds at Washington, D. C., to the memory of William Procter, Jr., if possible in 1817, the centennial anniversary of his birth. A committee was appointed to take the matter in charge, which since that time has been active in soliciting subscriptions. The names of contributors have been published from time to time in the annual volume of Proceedings (see Proc. 1906, p. 63; Proc. 1907, p. 98).

In September, 1907, at the annual meeting held in New York City, the Association
directed that all moneys collected for the Wm. Procter, Jr., Monument Fund, be turned over to the Treasurer of the A. Ph. A., to be deposited on interest for the benefit of said fund (see Proc. 1907, p. 99). The Treasurer of the A. Ph. A., in his annual report for 1908–1909, reports having received on January 27, 1909, the sum of $3,413.33 from the Treasurer of the Committee, Benj. T. Fairchild, which was placed on time deposit in the International Bank of St. Louis, Mo., for a period of twelve months at 4 per cent. per annum (see Proc. 1909, p. 472). Since July 1, 1909, $278.25 have been collected and added to the fund. The total sum to the credit of this fund, including interest on time deposits, according to the treasurer's report (see Proc., 1910, p. 479) on July 1, 1910, amounted to $3,894.92.

THE COLLEGE PRIZE FUND.

The Association holds this fund in trust for the National College of Pharmacy, Department of Pharmacy of George Washington University, at the request of Murray Galt Motter (see Proc. 1907, p. 54). The Treasurer, in his annual report for 1909–1910, states that no draft has been made against this account since it was opened August 4, 1905. The amount of the fund, including interest, is $29.82.

THE EBERT LEGACY FUND.

The late Albert E. Ebert having by his will designated the A. Ph. A. as residuary legatee of his estate, it was ordered at the fifty-eighth annual meeting, on recommendation of the committee on invested, savings and trust funds, that the money received from the estate be converted into a fund to be known as the Ebert Legacy Fund, and that this fund be invested in municipal or other public bonds approved by the committee on invested, savings and trust funds and the finance committee, and that this fund be kept intact and the income added thereto until the fund and its accumulations shall together amount to a total of $10,000.00.

When this sum has been reached, the income derived from the fund shall be devoted to such purposes as will, in the opinion of the Council, best commemorate the founder of the fund and his services to pharmacy.

The reason for the suggestion that the old Ebert Fund and the Ebert Legacy Fund be kept separate was, that the first was given by Mr. Ebert for a specific purpose, while the latter was given to the Association practically without restriction and with the evident intention that the Association should use it in the manner which it deemed best.

On December 14, 1909, the executors of the Ebert estate paid over to the treasurer of the A. Ph. A. the sum of $2800.00, which has been deposited in bank at interest. The treasurer's report, see page 477, states that on July 1, 1910, this fund amounted to $2844.00.
ABSTRACT OF PROCEEDINGS OF THE ELEVENTH ANNUAL MEETING OF
THE AMERICAN CONFERENCE OF PHARMACEUTICAL FACULTIES,
HELD AT RICHMOND, VIRGINIA, MAY 2–7, 1910.

Twenty-six colleges of pharmacy were represented by delegates at this the eleventh annual meeting. On account of the death of the President of the Conference, Wm. M. Searby, the Vice-President, E. H. La Pierre, presided at the meetings.

The Vice-President in his address called particular attention to the growth of the Conference from seventeen schools at its organization in 1900 at Richmond, Va., to thirty-three schools now holding membership.

The report of the Chairman of the Executive Committee showed that the Conference was doing much toward assisting in raising the standards of pharmaceutical education.

The pharmaceutical syllabus was carefully considered and the conference voted to approve its general scope and purposes. The following were elected to represent the Conference on the general Syllabus Committee: J. H. Beal, H. H. Rusby, J. O. Schlotterbeck, J. A. Koch, W. C. Anderson, C. B. Lowe and H. V. Arny.

The By-Laws of the Conference were amended so as to provide that one year of high school shall be the minimum requirement for entrance to all schools holding membership in the Conference.

Prof. J. T. McGill, of Vanderbilt University, read a paper on “The High School in the Southern States.” The aim of Prof. McGill’s paper was to show that the Southern states had ample high school facilities to prepare students to meet the minimum requirement of one year’s high school work.

The following persons were elected as officers of the Conference for the year 1910–1911: President, J. O. Schlotterbeck, University of Michigan, Ann Arbor; Vice-President, W. J. Teeters, State University of Iowa, Iowa City; Secretary-Treasurer, Charles W. Johnson, University of Washington, Seattle; Executive Committee, Chairman, J. A. Koch, Pittsburg College of Pharmacy, Pittsburg; H. C. Stroup, Philadelphia College of Pharmacy, Philadelphia; E. G. Eberle, Baylor University, College of Pharmacy, Dallas, Texas; E. H. La Pierre, Massachusetts College of Pharmacy, Boston; J. M. Good, St. Louis College of Pharmacy, St. Louis.
REPORT

ON THE

PROGRESS OF PHARMACY.

FROM JULY 8, 1909, TO JUNE 30, 1910.

BY C. LEWIS DIEHL.

The ninth decennial Convention for the Revision of the Pharmacopoeia of the United States of America has been held at the appointed time, beginning its sessions almost to the hour, and, having deliberated and passed upon certain rules governing the function of the Board of Trustees, declared the principles that shall control the revision, elected its officers, and appointed a Committee of Revision (increased from 25 to 50 members) to prepare and submit the manuscript for a revised edition of the Pharmacopoeia, it has now passed into history.

This is not the place to enter into details regarding the character of the work accomplished by this convention, which was fairly representative of the kindred professions of medicine and pharmacy, nor of the instructions given; but as an evidence of progress, with which this report is immediately concerned, attention may properly be directed to the fact that, as at previous Conventions, the profession of pharmacy was well in the advance with suggestions, which have made it possible to declare the principles that are to govern the coming Revision, in a satisfactory and expeditious manner. This is not mentioned in a captious spirit, but simply to emphasize the progressive tendency that prevails among pharmacists in the furtherance of their profession, in spite of the modern tendency to commercialize the practice of pharmacy.

The report herewith presented will give abundant evidence of this commendable spirit within the ranks of the pharmaceutical profession, and ( 1 )
this evidence is augmented by the numerous papers, and the discussions thereon, that were presented at the 58th Annual Meeting of this Association, held during the week immediately preceding the Pharmacopoeial Convention; while the Synopsis of the work in the local branches of the Association, following these introductory remarks, must convincingly prove that the interest awakened for the betterment and revision of our two legal standards of authority—the U. S. Pharmacopœia and the National Formulary—however dormant it may have been in the past, has become a living issue.

PROCEEDINGS OF THE LOCAL BRANCHES OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

(SEASON 1909-1910).

BALTIMORE BRANCH.

October, 1909.—The opening meeting of the Branch for the Winter of 1909-1910 was held on the 21st of the month at the Hotel Caswell, Vice-President Lowry presiding. Chas. Caspari, Jr. opened with a general review of the Los Angeles meeting of the Association and the important work accomplished at that meeting. In consequence of a recommendation embodied in a report of the Committee on Education and Legislation, it was resolved: “That the Baltimore Branch of the American Pharmaceutical Association pledges its support to the proposed Pure Food and Drug Bill now in the hands of the Maryland Pharmaceutical Association,” a copy of which was presented. Resolutions of regret at the death of Alpheus P. Sharp (one of the oldest and most respected members of the A. Ph. A.) were also adopted, and the Secretary was instructed to notify Mr. Sharp’s family of this action. Attention was called to some amendments of the Maryland Pharmacy Law, which the Board of Pharmacy proposed to ask the General Assembly to enact at the coming session, which were discussed, but no definite action was taken. John B. Thomas was unanimously elected a member of the Council of the A. Ph. A. to represent the Branch for the next three years. Attention was also called to a vacancy on the General Membership Committee of the A. Ph. A. for Maryland, but no action was taken.

December, 1909.—The programs of the November and December meetings were combined at the meeting held on the 16th of this month at the Hotel Caswell, J. F. Hancock presiding in the absence of the President and Vice-President. The National Formulary Revision was the subject of discussion in the following order: (1) Basic elixirs and compound spirits; (2) formulas for alcoholic solutions of volatile oils; (3) color standards; (4) character and exact definition of non-official ingredients; (5) elimination of notes; (6) additions to the N. F. The discussions
were held as general as possible and the decisions reached, which seemed to represent the opinions of all, are briefly to the effect: (1) That the inclusion of a few (new) basic elixirs would be desirable; (2) that a general formula, but not specific formulas, for the preparation of alcoholic solutions (spirits) of volatile oils, was considered desirable; (3) that uniformity in the color of preparations could be more likely secured by the use of definite quantities of coloring materials made by a definite formula than by the use of color charts or other color standards; and (4) that it was considered advisable to eliminate general notes. An expression of opinion on the other questions was deferred.

January, 1910.—The annual meeting for 1910 was held at the Hotel Caswell on the 20th of the month, President Hynson presiding. After dispensing with the usual reports and the election of officers for the ensuing year (W. J. Lowry, Jr., President; C. L. Meyer, Vice-President; E. F. Kelly, Secretary-Treasurer), the National Formulary questions, consideration of which was deferred at the last meeting, were taken up and discussed by the members generally, the consensus of opinion being: (1) that non-official ingredients should be defined and wherever possible, standardized, in the N. F.; and (2) that no action be taken at present as to additions to the N. F.

March, 1910.—The program which had been arranged for the meeting of the Branch on March 17th was postponed on account of the interest being taken in the bills before the Maryland General Assembly affecting pharmacy. The meeting was held in the Lecture Hall of the Department of Pharmacy of the University of Maryland, President Lowry presiding. The Executive Committee having secured the attendance of several gentlemen who were thoroughly posted as to the important points of these bills, the discussion proved to be very interesting. As a result the Secretary was instructed to ask on behalf of the Branch, the support of each member of the General Assembly to the Pharmacy Bill.

Chicago Branch.

October, 1909.—The first meeting of the season was held on the 19th of the month at the Northwestern University building, First Vice-President Storer presiding. In a letter received from President Oldberg, accounting for his absence by reason of his precarious health, occurs the following passage, which will doubtless be appreciated by those best acquainted with his character:

"Please assure my fellow-members that the National Formulary has no truer friend than myself. My criticism of the looseness of Congressional legislation is not in any sense or degree a criticism of the N. F., and my criticism of the N. F. had for its sole object a desire to awaken a realization of the truth that the book, in order to retain its legal authority as a standard, must cease to be a private property of any independent corpo-
ration, and at the same time must be indisputably worthy of the same respect which we bestow upon the Pharmacopœia. I confidently hope and believe that the present Committee on the N. F. is successfully working to that end. A calm and unbiased reading of what I said in my presidential address, read at Los Angeles, ought to convince anyone that any other construction put upon my remarks about the N. F. is a mistaken one."

After the brief reports from the various standing committees were disposed of, the agreed topic for discussion, the Revision of the National Formulary, was taken up as per program, the particular subjects for the evening being: "General Principles: Shall Introductory Notices of Instruction be eliminated?" and "Alcoholic Strength of Elixirs." These were thoroughly discussed by the members present, and the following unanimous conclusion reached regarding the first mentioned subject. "We believe that the principle of General Formulas and Introductory Notices as at present included in the N. F. should be maintained in the next revision." On the second subject no definite action was taken; but it seemed to be the consensus of opinion that "the alcoholic strength of elixirs should be lessened wherever possible." It was decided that the program for the next meeting should be: "Additions to the N. F.;" "Flavors of the N. F.;" "Emulsions of the N. F."

November, 1910.—The second meeting of the season was held at the Northwestern University building on the 16th of the month, Vice-President Storer presiding. The discussion of the Revision of the National Formulary was continued as planned last month, the first in order being the subject of "Additions" which elicited an interesting paper from Otto E. Bruder, who proposed four new tinctures—ambrosia, cactus, passiflora, and pulsatilla—and two new elixirs—cardamom comp. and vanillin comp. He objects to the introduction of any codliver oil extracts, or wine made from this but recommends instead that more attention be given to a palatable form in which codliver oil itself might be administered. Incidentally, Mr. Bruder suggested a simplification of the (general) formula for fluidextracts, and this feature provoked considerable discussion. A paper of Theodore I. Scheipe, called up the subject of "Emulsions," which also provoked animated discussion, particularly in reference to his suggestion and strong recommendation of eggs and milk as emulsifying agents. The subject of "Flavors of the N. F." was postponed for discussion at the next meeting of the Branch.

December, 1909.—On account of the holiday season the meeting of the Branch, held on the 21st of the month at the Northwestern University building, was attended by a smaller number of members than usual. Nevertheless, the meeting proved unusually interesting from the unexpected presence of several guests of honor—President Huhn, of the N. A. R. D., Manager Goddard, of the A. D. S., and Professor Anderson, of the Brooklyn College of Pharmacy—the latter making a very interesting address
bearing on the work of the Association, on the effect of the prerequisite law in New York State, on the coming revision of the U. S. Pharmacopoeia, etc., which was followed by some interesting remarks by President Huhn bearing on the higher professional standing of "Pharmacy," which, in his opinion, can be brought about only if pharmacy is made sufficiently lucrative to attract intelligent, well-educated and capable youths. The meeting closed with the nomination of the officers to be elected at the January meeting.

January, 1910.—At the request of Vice-President Storer, seconded by the members present, Mr. Leo Eliel, of Indiana, consented to preside at this meeting, which was held on the 25th of the month at the Northwestern University building, as usual. The nominees for officers of the Branch, to serve during the ensuing year, were confirmed by the unanimous vote cast at the election held as the first business in order—these officers being: C. A. Storer, President; E. N. Gathercoal, First Vice-President; L. A. Becker, Second Vice-President; Mrs. M. M. Gray, Third Vice-President; W. B. Day, Secretary-Treasurer. After receiving and disposing of reports from the Committee on Medical Relations, and from the Committee on Public Relations, the regular program of the meeting was taken up by a "Discussion on the Revision of the U. S. P.," Dr. H. M. Gordin leading with a paper in which he advocated "the elimination of the common identical tests for chemicals," and recommended descriptive definitions for galenical preparations. This paper was followed by one of Professor A. H. Clark, discussing "the official alkaloidal assay processes" as they now appear in the Pharmacopoeia. After an animated discussion by Messrs. Puckner, Eliel, Hallberg, Gordin and others, Professor Clark closed by saying that in his mind there is no doubt that since the Pharmacopoeia is adopted by law as the standard, the methods of assay should be complete and given in detail. The interest in this meeting was enhanced by the presence of a number of distinguished visitors from other States, members of the A. Ph. A., who responded to the motion of the Chairman by felicitous expressions regarding the work of the Branch as exemplified on this occasion. On closing the meeting it was announced that the proposed amendments to the Illinois Pharmacy Law and a demonstration of the physiological standardization of digitalis would be included in the program of the February meeting of the Branch.

February, 1910.—The stated meeting was held at the usual meeting place on the 15th of the month. In accordance with the program Chairman Wells of the Committee on Legislation of the Illinois Pharmaceutical Association, presented the draft of the proposed revision of the Illinois Pharmacy Act, which was in the main approved by the members present, who seemed to be of the opinion that the features presented in the draft would be very great improvements over the present law. Of paramount interest on the program, however, was a demonstration by Dr. Bernard
Fantus of the College of Physicians and Surgeons of the University of Illinois "On the Physiological Assay of Digitalis." Dr. Fantus discussed the various methods of physiological assay of this drug and the advantage of using cold blooded animals, especially frogs. He then demonstrated the technique, using frogs injected with measured amounts of infusion of digitalis, and, while waiting for the development of the physiological effect, discussed the comparative action and strength of the different preparations of digitalis. While the author prefers the use of the infusion in his practice, the tincture has been found more active than the infusion. Incidentally, also, he found that the official infusion keeps remarkably well as compared with a simple aqueous infusion. Dr. Fantus can see no necessity for fluidextract of digitalis leaves, the tincture being sufficiently concentrated. The finest selected digitalis leaves should be used for preparing the infusion; the use of the fluidextract instead of the drug for making the infusion, would be almost a crime. At the close of the meeting it was announced that at the stated meeting in March a symposium on the U. S. P. and N. F. would be held.

March, 1910.—The meeting of the Branch held on the 15th of this month at the usual meeting place, was one of the most interesting of the season, nearly seventy members and medical friends attending. By request, Mr. Leo Eliel, of Indiana, presided and presented the speakers participating in the "Symposium on the U. S. P. and N. F." composing the announced program. Prof. Hallberg summarized the salient features of the subject selected, saying that the principal criticism by pharmacists has been the nomenclature, the purity standards, and the retention of certain compound preparations and mixtures in the U. S. P. whereas some medical men are opposed to such drugs and preparations as in their opinion have no decided therapeutic action. They favor extension of the standardization principle to such drugs whose activity can only be determined by physiological assay. Dr. Lyman F. Kebler followed, discussing the status of the Pharmacopeia as a legal standard and its bearing on importation of drugs and chemicals. He instanced the character of adulterations, and the permissible presence of foreign material, and emphasized the great need of authentic botanical specimens for the identification of drugs, regarding however as satisfactory the results given by the official assay processes. Concerning the suggestion that "The Compound Preparations and Mixtures be dropped or transferred to the N. F.," Dr. Jas. G. Kiernan says that physicians ought to be slow to suggest the omission of such mixtures as had born the test of time and were still in demand. Many of these compound preparations have been tested and approved clinically. He was of the opinion that the action of medicines on the lower animals, such as frogs could not be accepted as a criterion of the effect on man. Moreover, the synergistic effect of a combination of drugs might differ greatly from that of any one of them. Dr. Wm. L. Baum, the
next speaker, agreed with Dr. Kiernan that we stand on the threshold of
a knowledge of the physiological action of drugs. The physiological
chemist cannot explain what becomes of a drug when taken into the
system or how it produces its effects. After an exhibit by C. M. Snow of
the summaries from a tabulation of one hundred thousand prescriptions, a
general discussion followed, from which it became evident that the par-
participants at this meeting do not favor the dropping of compound prepara-
tions from the Pharmacopoeia.

April, 1910.—The last meeting of the season 1909-1910 was held on
the 15th of the month at the Northwestern University building, President
Storer presiding. After the disposal of a number of reports the reg-
ular program of the evening, Discussion of General Principles for Re-
vision of the U. S. P. was taken up, and disposed of in 10 sections, with
results as follows:

1. The present plan of nomenclature for synthetic products, using ab-
   breviated chemical names was approved.

2. The proposal to adopt the atomic weights as furnished by the In-
ternational Committee (O-16), was not opposed.

3. The vote on restoring important synonyms to the text of the U. S. P.,
is in the affirmative.

4. The attention of the temperature for specific gravities at 25° C., oc-
casioned a general discussion, resulting in the reference of the whole
matter to the Government Bureau of Standards.

5. The inclusion of general directions for determining physical constants
in the U. S. P. is recommended.

6. In view of the proposition from some quarters that such drugs as are
fully represented by their active principle be dropped, it is the opinion of
the Branch, prevailing at this meeting, that these drugs and the galenical
preparations made from them should not be discarded in favor of active
principles which are presumed to represent them.

7. The question of recognition of distilled spirit in the U. S. P. was the
subject of differences of opinion which left it undecided.

8. It was unanimously recommended that general processes and formu-
las, reducing the present details of description in each case, be intro-
duced in the U. S. P.

9. The suggestion that the alcoholic strengths of menstrua be given by
volume percentage with a general method in tabular form for preparing
these various percentages, thus doing away with much detail in the body
of the text, is approved.

10. It is recommended that a classification of methods of storing and
preservation be adopted.

At this meeting also a resolution introduced by Mr. Bruder, which pro-
vides that the N. F. should be revised by means of an annual supplement
having the same legal value as the Formulary itself, was discussed and
referred to the Committee on National Formulary.
Denver Branch.

January, 1910.—The first meeting of the season was held on the 11th of the month, President Bresler presiding, who, in calling the meeting to order, announced that a discussion of the N. F. revision was the principal topic of the evening's program. He called attention to the adverse criticism of the N. F. by many of the pharmaceutical journals and recommended protest. A. W. Clark, in view of the fact that many of the substances directed in the formulas of the N. F. have no standard of quality, strength or purity, recommended the adoption of such standards for the revised edition. The subject of using fluidextracts in the production of elixirs was criticized unfavorably, it being the sense of the meeting that—the strong alcoholic ones in particular—should not be so used, or when therapeutic value or elegance were sacrificed for simplicity of process. Several new preparations—"Elixir of Saw Palmetto and Santal Compound," "Aromatic Castor Oil," and "Syrup of White Pine Compound with Codeine and Tar"—were proposed, and formulas are given by Mr. Nitardy for the last two in the A. Ph. A. Bulletin (Feb., 1909, 96). The subject of color standards was discussed. It was suggested that caramel solution might be standardized by comparing a definite dilution in a specific manner with a color plate, while Charles M. Ford suggested the possible utility of a harmless coal-tar dye as a substitute for cudsuar. A series of three resolutions were adopted bearing (1) on the remuneration for expenses of delegates to the U. S. P. Convention; (2) on the practice of manufacturing houses to attach labels to their fluidextract containers for making other preparations from them; and (3) on the (alleged) enlistment of the pharmaceutical press of this country, with but few exceptions, in the cause of those whose interest it is to lower the standards and emasculate the tests of the U. S. P.

The election of officers being in order, on motion the present officers were elected to serve another year, viz.: S. L. Bresler, President; Chas. M. Ford, Vice-President; F. W. Nitardy, Secretary-Treasurer.

February, 1910.—The stated meeting of the Branch was held on the 15th of the month, President Bresler presiding. After the reading of an interesting paper by L. L. Alkine "on Diphtheritic Antitoxin and Globulin" the "U. S. P. Revision" was taken up as per announced program and a general discussion resulted, bearing on a variety of subjects which may be consulted in the A. Ph. A. Bulletin March 1910, 166-167). Several preparations of the N. F. Comp. Syrup of Phosphates, Elixir of Potassium Bromide, and Petroleum Emulsion—also came in for brief criticism. On closing the meeting it was announced that the discussion of the U. S. P. would be continued at the next stated meeting.

March, 1910.—The stated meeting was held on the 15th of the month, Vice-President Ford presiding. The secretary submitted a set of by-laws for the Branch, which he was instructed to prepare. These, on motion
of Mr. Best, were provisionally adopted, a final vote to be taken at the next stated meeting. The principal topic of discussion consisted of a series of thirteen questions on the U. S. P., sent out by Dr. Reid Hunt, chairman of the Committee on the U. S. P. of the American Medical Association. These, with the action taken, may be referred to in the A. Ph. A. Bulletin (May 1910, 282-284). Mr. Nitardy suggested that an annual supplement to the U. S. P. might be of value, if restricted to additions, to meet the complaint, voiced by Dr. Moleen, that physicians fail to take as much interest in the U. S. P. as they ought to, because of the delay in its publication.

April, 1910.—The stated meeting was held on the 20th of the month, after the Branch had been entertained at dinner by Mr. W. A. Hover. After a rising vote of thanks to Mr. Hover, President Bresler called on Mr. Charles Clayton for a paper on the "Synonyms in the U. S. P.", who says among other things that the extent to which the use of synonyms should be carried in the text of the U. S. P. is a question upon which there is a wide diversity of opinion. It would be unreasonable to expect that all common names should be given for every drug mentioned, but on the other hand, it would seem to be not only reasonable, but almost imperative, that the names by which various drugs and preparations are best known should be included as synonyms. The compilers of the present Pharmacopoeia attempted to dignify the work by substituting for the commonly known English names of many articles, an anglicised form of the Latin name. This, however acceptable to physicians, pharmacists and scientists, failed of success because, so far as the retail druggist is concerned, the bulk of his business is done with the comparatively un-educated public, who ask for what they want by the names to which they are accustomed, which names in many instances are not to be found in the Pharmacopoeia. As to the use of copyrighted names of the synthetic chemicals as synonyms for their official counterparts, it would seem to be doubtful wisdom to give their rivals the advertising advantage which would occur if their names were mentioned. On the other hand, the present official names of some of these articles are rather long and cumbersome and it would seem that the adoption of some shorter and more easily memorized synonym might result in their more frequent prescription. In the discussion following it developed that the members generally coincided with the views so ably presented by Mr. Clayton, which were fully endorsed. A series of resolutions circulated by the N. W. D. A., concerning the forthcoming revision of the U. S. P. were presented at this meeting and after discussion and deliberation were adopted by a unanimous vote. A number of other questions of minor importance were discussed but no action taken. The Branch then adjourned, the date of the next meeting to be determined after the return of the delegation from the U. S. P. Convention.
NASHVILLE BRANCH.

May, 1909.—Owing to the large accession of members in Tennessee through the efforts of Mr. Burge and his associates, a Branch has been organized in Nashville with over thirty members.

June, 1910.—A meeting of the Branch was held on the 9th of the month, with the following officers present:—J. O. Burge, President; Ira B. Clark, Vice-President; Lucius P. Brown, Secretary. President Burge read a paper on the subject of weights and measures, stating that he had used the metric system exclusively in manufacturing and found it was convenient and much easier than the old system. The president's experience was the principal subject of discussion in which a number of members participated. Measures were inaugurated to furnish topics of interest for discussion at the stated meetings of the Branch. The topics for discussion at the next meeting will be “What Books Should Be in the Druggist's Library,” and “Filtration.”

NEW ENGLAND BRANCH.

December, 1909.—The annual meeting of this Branch was held at Hotel Plaza, Boston, on the 7th of the month; the following officers were elected for the ensuing year: James E. Finneran, President; James O'Hare, Vice-President; R. Albro Newton, Secretary-Treasurer. The principal topic discussed at this meeting was the next revision of the Pharmacopoeia. A number of suggestions were made, but no formal action was taken. The Branch adjourned without deciding upon the date of the next meeting.

January, 1910.—The meeting held on the 11th of this month at Hotel Plaza, Boston, was attended by a committee appointed by the Massachusetts Medical Society to consider the Pharmacopoeial revision, and proved very interesting. This committee thought that a smaller book would be most agreeable to the physicians in general, toward which end they had sent out 3000 pamphlets containing a list of official articles asking that the members indicate which they desired to have omitted. The fact that 50 per cent. had done as requested shows remarkable interest in this work. No definite action was taken at this meeting, the discussion being practically confined to matters pertaining to the U. S. P.

February, 1910.—The meeting held on the 18th of the month at the Hotel Plaza, Boston, was again attended by several members of the Massachusetts Medical Society, and the principal topic of discussion, as at the previous meeting, was the revision of the U. S. P.—the discussion, however, tending more toward details regarding the individual preparations. Elie H. LaPierre was re-elected as a member of the Council from this Branch.

April, 1910.—The last regular meeting of the season was held at Hotel Plaza, Boston, on the 13th of the month, and was unusually well attended. Although the subject for discussion was to have been the first twenty-five
articles in the N. F., much time was given to a discussion of the laws in Massachusetts and Rhode Island. The only change recommended in a N. F. preparation was in the process of hydrated oxide of bismuth, which seems most unsatisfactory. The question of doses in the U. S. P. was discussed, but no agreement was reached as to the character of the doses, some favoring average doses, others the maximum. It was voted to invite the Association to meet in Boston in 1911.

NEW ORLEANS BRANCH.

October, 1909.—The sixth monthly meeting (of the year) was held in the rooms of the New Orleans College of Pharmacy, President Godbold presiding. As this was the first meeting since the close of the summer months, there was no scientific program for the evening. Mr. Philip Asher gave an entertaining account of his trip to the Pacific Coast and of his attendance at the Los Angeles meeting of the Association. Mr. Godbold also spoke of Association matters, calling attention to the great good the A. Ph. A. was doing. A number of topics for discussion at the next stated meeting having been announced, the meeting adjourned to partake of a substantial supper served in honor of President Godbold, the "Nestor" of Louisiana Pharmacy.

NEW YORK BRANCH.

November, 1909.—The first meeting of the season 1909-1910 was held on the 8th of the month. The only Committee report received was that of the Committee on Education and Legislation, and there was no set program, although subjects connected with the revision of the U. S. P. afforded abundant material for the discussions of the evening, which were participated in by Messrs. Diner, Mayo, Coblentz, Raubenheimer, Plaut, and others. In a paper "On the Assay of Opium and Its Preparations," which constituted a constructive criticism of the U. S. P., Dr. G. C. Diekman deplored the lack of definiteness in the official directions for extracting the samples and suggested a number of changes in the process which he regards essential. The paper was referred to the U. S. P. committee of the A. Ph. A. Following this, the Branch was entertained by a very instructive talk on "The Bacteriological Importance of Calomel," by Dr. S. P. Klein. After a vote of thanks to Dr. Klein, the Branch adjourned to meet on December 13th.

December, 1909.—The stated meeting of the Branch (the twenty-third in its existence) was held on the 13th of the month, President Diner presiding, with a large attendance of members and visitors. After a brief verbal report on pharmacal education in Germany, by Dr. G. C. Diekman, Chairman of the Committee on the Progress of Pharmacy, and the reading of an opinion given by State's Attorney General O'Malley on a mooted phase of the anti-cocaine law, a paper on "The Federal Law and the
Pharmacopœia" was read by Dr. H. H. Rusby, which proved to be the most interesting topic for discussion and practically engaged the attention of the Branch during the remainder of the evening. In summing up after the discussion on his paper (which was participated in by Messrs. Seil, Diekman, Roehrig, Lohman, Mansfield, Weinstein, Diner, Raubenheimer, McDowell, Gallagher, Flowers, Bigelow, Lascoff, McElhenie and Darling), Dr. Rusby held to his belief in a Pharmacopœia of more definiteness and wider scope, and to his advocacy of publicity. An evident attempt at secrecy and not a desire for publicity was, he said, recognized in law and ethics as justification for a presumption of ulterior motives. His motion, he said, was to preclude any advantage to any member of the committee in the publication of any commentary on the Pharmacopœia or work on materia medica; and also to have criticism before rather than after the adoption of a standard. On motion, the Secretary was instructed to have the paper by Dr. Rusby, and an abstract of the discussion printed and distributed to the delegates of the 1910 Pharmacopœial Convention.

January, 1910.—The meeting of the Branch, held on the 10th of the month, constituted the third annual meeting in its history and resulted in the election of the following officers: Otto Raubenheimer, President; A. M. Roehrig, Vice-President; Hugh Craig, Secretary; Joseph Weinstein, Treasurer. Reports were received from the committees on education and legislation, and from the committees on the science and practice of pharmacy, the latter presenting abstract translations of recent contributions to the German and French pharmacal literature. The attention of the Branch having been called by the retiring president to an objection which had been made to that portion of the report of the committee on the president's address at the Los Angeles meeting of the A. Ph. A. which had to do with the status of the pharmacists in the public service, the members were invited to discuss the subject, with the result that the Branch, by appropriate resolutions, places itself on record as disapproving the objectionable expressions regarding the pharmacist in the public service, as they appear in the aforesaid report on the president's address. The papers that engaged the attention of the Branch at this meeting were the following: "Linimentum Camphoræ," by G. A. Ferguson; "Note on the Assay of Opium," by E. L. Patch (of Boston); and "The Essential Oils of the U. S. P.", the latter being a translation of a paper by Paul Jeancard and Conrad Latie, of Cannes, France. These several papers were discussed by Messrs. Diner, Raubenheimer, Kleber, Seil and Dodge, and suitable acknowledgements were made to their authors.

February, 1910.—The stated meeting of the Branch, held on the 15th of the month, President Raubenheimer presiding, was devoted to the announced program, "Maceration and Percolation." These operations were authoritatively elucidated by Professors John Uri Lloyd and Remington, followed by President Raubenheimer, and Messrs. Beringer, Dunn,
Flowers, Dickman, Gallagher, Hirsman, Weinstein, Mayo, McElhenie, and Mayer, and should be consulted as reported in the A. Ph. A. Bulletin (March, 1910, 151-153). A report from the Committee on Education and Legislation led to the statement by Mr. Flowers that to require graduates of chartered colleges of pharmacy to pass a board examination in order to secure a license to practice pharmacy was to deprive the colleges of their constitutional rights, hence illegal, which was followed by considerable discussion. On closing it was announced that the National Formulary would be discussed at the next stated meeting.

March, 1910.—The stated meeting of the Branch, held on the 14th of the month, was devoted principally to a discussion of the revision of the National Formulary. Reports were received from the Committee on Membership, the Committee on Professional Relations, and the Committee on Education and Legislation. On motion of Mr. Mayo the last-named committee was instructed to express antagonism to the bill for certain specified reasons which came up during the discussion. President Raubenheimer opened the subject of the revision of the National Formulary, speaking in favor of a divided book: one part to consist of formulas, the other of descriptions and standards for simples used in these formulas and not recognized in the U. S. P. A. M. Roehrig brought up the question of the legal right of the A. Ph. A. to delete any formula from the N. F. since these were part of the law. Mr. Flowers emphasized the necessity of meeting the requirements of the medical profession in official preparations. Mr. Raubenheimer exhibited a number of improved N. F. preparations, and Mr. McElhenie also showed a number of preparations improved according to his own suggestion. These subjects gave rise to an animated discussion in which, in addition to the gentlemen mentioned, Messrs. Craig, McElhenie, Muir, Anderson, DeYonge, Weinstein, Mayer and MacDowell, participated.

April, 1910.—At this meeting of the Branch, held on the 11th of the month, the principal topic offered for discussion was introduced by the reading of a number of resolutions adopted by the Washington Branch to govern the Revision of the Pharmacopoeia. The discussion of these resolutions was opened by Dr. Rusby, who expressed himself as being opposed to the deletion from the Pharmacopoeial fold of any drug which was called for by physicians and public in the treatment of disease. Dr. R. A. Hatcher, who took a prominent part in the discussion, took a position opposed to the far-reaching Pharmacopoeia suggested by Dr. Rusby. Jacob Diner was of the opinion that there should be some legal standard for all drugs where such was possible, and that these standards should preferably be in the Pharmacopoeia, and this view was that of practically all the pharmacists present; but, in view of the equal standing of the N. F. before the law, all formulas for complex preparations might well be transferred to the N. F. The various utterances of the Washington
Branch were discussed also by Messrs. Anderson, Craig, Flowers, Gallagher, Goeckel, Lascoff, McElhenie, Roehrig, and Weinstein. The conclusions of the Branch are summed up in a number of utterances which may be consulted in the A. Ph. A. Bulletin (May 1910, 287-288).

A number of reports were received and disposed of at this meeting. Vice-President Roehrig, having been ordered to the Marine Hospital Station at Buffalo, and consequently resigned from the vice-presidency of the Branch, was elected an honorary president of the same. The death of P. C. Candidus, one of the oldest associates in time of membership and one of the honorary presidents of the A. Ph. A. was referred to by President Raubenheimer, who, with Messrs. Cook and Roehrig, spoke of the endearing qualities of the deceased. It was ordered that a page be set aside in the minutes in memory of Mr. Candidus and that a letter of condolence be sent to his widow.

**Northern Ohio Branch.**

November, 1909.—The stated meeting of the Branch was held on the 19th of the month, President Hopp presiding. The topics for discussion at this meeting were embodied in a paper prepared by M. G. Tielke in which a number of preparations of the U. S. P. and N. F. were criticized, embracing the following: Compound tincture of gentian; compound tincture of cinchona; elixir of calisaya; elixir of gentian; glycerinated elixir of gentian; bitter wine of iron; the several preparations of iron, quinine and strychnine; the several preparations of hypophosphites; and elixir of glycerophosphates. Various improvements were suggested, which were discussed by Messrs. Arny, Hopp, Fox and other members present. At the close of the meeting it was announced that the laxatives of the U. S. P. and N. F. would be discussed at the next meeting.

December, 1909.—At the stated meeting of this month the business consisted of a discussion of the laxatives of the U. S. P. and N. F. as previously announced. The discussion was led by Mr. Hankey and comparison of samples of the following preparations was made by the members present: Aromatic fluidextract of cascara sagrada; compound solution of sodium phosphate; emulsion of castor oil; confection of senna; effervescent magnesium sulphate; compound powder of rhubarb; compound powder of glycyrrhiza; and compound cathartic elixir.

January, 1910.—The stated meeting was held on the 28th of the month, President Hopp presiding. The topics for discussion were presented in a paper prepared by O. E. Muhlhan on the Expectorants of the U. S. P. and N. F., which were represented by several samples of the preparations discussed and made by the pharmacists present. The following preparations were criticized: Compound tincture of benzoin, compound syrup of squills, syrup of tar, wine of tar, mixture of ammonium chloride, syrup of senega, and compound mixture of glycyrrhiza. The following officers were
elected for the ensuing year: Lewis C. Hopp, President; William T. Hankey, Vice-President; H. V. Arny, Secretary-Treasurer.

April, 1910.—The stated meeting was held on the 15th of the month, President Hopp presiding. The subject of "Color Standards" was presented in a paper prepared by Professor Feil, who in the discussion following was ably seconded by Professor Arny. This interesting discussion may be consulted in the A. Ph. A. Bulletin (June, 1907, 371).

Northwestern Branch.

October (?), 1909.—At a meeting held at the Niccollet Hotel, Minneapolis, President Wulling presiding, the chief business was the election of officers, which resulted as follows: W. A. Frost, President; Stewart Gamble, Vice-President; Frederick J. Wulling, Secretary-Treasurer.

January (?), 1910.—At the meeting held at the Niccollet Hotel, Minneapolis, the newly-elected president, W. A. Frost, presiding, the question of consolidating the Pharmacopoeia and the National Formulary into one volume was presented for discussion, but was quickly decided in the negative. After an address by the retiring president, F. J. Wulling, and a brief response by the incoming president, W. A. Frost, the regular program of the evening was presented in a paper on "The Ownership of the Pharmacopoeia," read by F. J. Wulling. Animated discussion followed, participated in by Messrs. Gamble, Wittich, Melendy and Vøegeli, the sentiment of the meeting being crystallized by the unanimous adoption of a motion opposing the ownership of the Pharmacopoeia by the government. The rest of the evening was devoted to the matter of the coming Pharmacopoeial revision, and on the question of the desirability of a National Board of Health. The latter was favorably emphasized, but the majority opposed the suggestion that the publication of the Pharmacopoeia should be turned over to some such department, maintaining that the present method of revision should be continued.

Philadelphia Branch.

October, 1909.—The first of the season's meetings of the Branch was held at the College of Physicians on the 5th of the month, President Blair presiding. This meeting following after the annual meetings of the different affiliated bodies had been held was mainly devoted to the reception and discussion of the reports presented by the different delegations, such as the delegates to the American Medical Association, the Pennsylvania Pharmaceutical Association, the A. Ph. A., the N. A. R. D. and the N. W. D. A. The proceedings of this meeting may be consulted in the A. Ph. A. Bulletin (Nov., 1909, 439-441).

The first meeting for this season of the Scientific Section of the Branch, was held October 14th and was devoted almost entirely to the discussion of digitalis, which was considered in detail from the viewpoint of Pharma-
cognosy, Chemistry, Physiological Standardization, and Therapeutic Uses, by men who have made a special study of the drug in their respective vocations—this forming a highly interesting "Symposium upon Digitalis," which may be consulted in its entirety in the A. Ph. A. Bulletin (Dec., 1909, 491-493). Professor E. L. Newcomb, who has grown digitalis under many conditions at Vineland, N. J., presented in a clear, concise, and logical manner the "Pharmacognosy of Digitalis." Professor Charles H. Kimberly presented the intricate "Chemistry of Digitalis" in a masterly way. Dr. T. Stotesbury Githens pointed out the necessity of the "Physiological Standardization of Digitalis;" and Dr. Henry Beates, Jr., in a very able and original way described the action and "Therapeutic Uses of Digitalis," enumerating brifly his observations during many years of clinical study of the drug. The discussion following the reading of these papers was participated in by Drs. Wm. E. Robertson, Worth Hale, H. C. Wood, Jr., and E. A. Hoffer, Mr. J. K. Thum, and Professors I. V. Stanislaus and J. P. Remington.

November, 1909.—The meeting of the Scientific Section of the Branch was held on the 11th of this month at the Medico-Chirurgical College, and constituted a "Symposium upon Medicinal Chemicals" in which much valuable information was presented. Professor Virgil Coblentz spoke on the subject of "Improvements in Tests of Medicinal Chemicals," and Dr. George D. Rosengarten spoke of the "Manufacturing of Medicinal Chemicals" and the many requirements of the 1900 Pharmacopoeia that could not be practically complied with, referring, however, to the fact that these objections were largely overcome by the corrections later sent out. The details of this symposium may be consulted in the A. Ph. A. Bulletin (Dec. 1909, 493-494).

The regular meeting of the Branch was held on November 2nd, and was mainly devoted to topics connected with the "Prescription." Dr. E. L. Thornton presented an instructive paper on "Modern Methods of Teaching Prescription Writing in Medical Schools"; Mr. Franklin M. Apple a contribution in which he considered "The Prescription from the Pharmacist's View-Point"; and Dr. Daniel J. McCarthy gave an extemporaneous talk on "The Prescription—Copy or Label—Indiscriminate Renewals—and a Brief Consideration of the Legal Aspect." The final topic, "Who Owns the Prescription," was discussed in an interesting way by Messrs. Cliffe, Wood, LaWall, Cattell, Poley, Blair, Cabell, Thum, and others, all of whom agreed that it belonged to the pharmacist.

December, 1909.—The stated meeting of the Branch was held on the 2nd of the month in Cadwallader Hall, in the magnificent home of the College of Physicians. The program of the evening included discussions of "The Report of the Committee on the U. S. P. of the A. Ph. A." and "The Pharmacist's Part in the Coming Revision of the U. S. P." The topics thus brought up were interestingly discussed by Messrs. Blair, Koch,
Apple, England, Morgan, Beringer, Cook, Remington, Stanislaus, Kraemer, LaWall, Beates, Krauss, Pearson, Brinton, and others not named in the report of the meeting. The consensus of opinion appeared to prevail that the retail pharmacist would be very much in evidence with valuable suggestions at the coming convention and in the revision of the U. S. P.

The Scientific Section of the Branch held its regular monthly meeting at the Laboratory of Pharmacology, University of Pennsylvania, on the 9th of the month, the subject of the evening being "The Mydriatic Drugs." Prof. Henry Kraemer presented a paper on "The Pharmacognosy of the Mydriatic Drugs" which were considered in an admirable and highly instructive manner under eight botanical subdivisions. Mr. Joseph L. Turner in a most interesting way discussed "The Chemistry of the Mydriatic Alkaloids" namely: Atropine, hyoscyamine, pseudo-hyoscyamine, hyoscine, atropamine, belladonnine, and scopalamine. L. H. Bernegau made a number of "Suggestions for Improvements of U. S. P. Methods for Assay of Mydriatic Drugs," and recommended the addition of fluidextract of belladonna leaves and solid extract of belladonna root, with standards, in the U. S. P. "The Pharmacology of the Mydriatic Drugs" was ably presented by Dr. H. C. Wood, Jr., through whose courtesy the beautiful Laboratory of Pharmacology was opened for inspection of the members present at this meeting. The subject of the evening was discussed by Drs. Stanislaus, Morgan, Hoffer, Kimberley and Cohn, Professors Kraemer and Lawall, and Messrs. Apple, Cliffe, Turner, Blair, and Pearson. A detailed report of this meeting appears in the January number of the A. Ph. A. Bulletin (p. 27–28).

January, 1910.—The regular meeting of the Branch was held on the 6th of the month. Resolutions of respect to the memory of Mahlon N. Kline were adopted and directed to be engrossed and sent to the bereaved family. The principal topic for discussion was "The National Formulary," Mr. Apple opening the discussion by directing attention to the dignity acquired by the work since its creation as a standard under the Food and Drugs Act, which makes it incumbent on the A. Ph. A. in the present revision to make it quite as dignified a work as the U. S. P. Mr. Apple was followed by Professor Cook, who gave some information as to what was being done in this direction by the N. F. Committee in the present revision, and he was followed by criticisms and suggestions made by Messrs. Blair, Cliffe, Cattell, LaWall, Brinton, Minehart, Kendig, and Stanislaus, which may be consulted in the A. Ph. A. Bulletin of March (p. 159–161). In the face of much unfavorable criticism developed by the discussion, Professor Stanislaus made a strong plea in defense of the N. F. He said that this book, which was welcomed a few years ago as the "sure cure for the ailments of medicine and pharmacy," was now characterized in some quarters as the "creation of substitutors and frauds, a miserable jumble of slip-shod formulas and a collection of therapeutic monstrosities." The
cry for simples and criticism of mixtures he regards as untimely, since the large mass of general practitioners will prescribe mixtures, and if the pharmacist fails to produce them he simply plays directly into the specialty manufacturer's hands. It is here where the N. F. shoe pinches the most.

The Scientific Section of the Branch held its January meeting in the library of the H. K. Mulford Company, the subject of the evening being "Standards for Volatile Oils." Dr. I. V. S. Stanislaus opened the subject by presenting a resume of the very extensive data he had collected from many sources. This was followed by a paper received from Dr. Wm. Ungerer of New York, entitled "Who makes the Adulterator?" to which he answers "the purchaser!" because he is the one who demands a product below the actual cost of production. Dr. Ungerer also presented a paper entitled "The Would-be Perfumer," in which he stated that the success of a perfume depends on three factors: (1) highest quality of materials; (2) perfect formulae; (3) expert manipulation. Dr. Ungerer named those anticipating entering this line of work to consider the many difficulties that are sure to be encountered. The reading of these papers was followed by an animated discussion, bringing out interesting points, participated in by Messrs. Brinton, Sadler, Remington, Pancoast, LaWall, Kimberly, Miller, Hilts, Swinton, Graham, Vanderkleed, and Pearson. (See A. Ph. A. Bulletin, Febr., 1910, 107-109).

February, 1910.—The stated meeting of the Branch was held on the 3d of the month, and after the consideration of routine matter, was devoted to the consideration and discussion of a series of suggestions for improvements in the N. F., presented by Mr. Joseph W. England, and of a number of papers on the National Formulary contributed by other members of the Branch. After considerable discussion it was considered advisable to postpone action on Mr. England's suggestions until the next stated meeting, when they were to be taken up seriatim. The first paper of the evening was presented by Franklin M. Apple on "Alternation Weights and Measures in the N. F. From the Pharmacist's Viewpoint." This was followed by a paper by C. Mahlon Kline, entitled "The N. F. from the Standpoint of the Manufacturer"; a paper by George M. Beringer on "Some of the Dangers and Responsibilities of the N. F. Revision," and a paper by E. Fullerton Cook on "Sterilization in the N. F." John K. Thum also presented an interesting series of suggestions for improvements in the U. S. P. and N. F. The discussion following the reading of the papers mentioned (which appear in the A. Ph. A. Bulletin of April, 215-221) was participated in by Messrs. LaWall, Thum, Stanislaus, Kraemer, Koch, Stundt, Blair, England, and others.

The Scientific Section of the Branch held its meeting at the Temple University on the 10th of the month, the subject of the evening being "Synthetic Remedial Agents." Dr. C. E. de M. Sajons opened by dis-
cussing the synthetic from the standpoint of their "Therapeutics." This was followed by a paper by Prof. Chas. H. LaWall on "The Manufacture of Synthetic Compounds;" and a paper by Prof. Charles E. Vanderkleed on "The Chemistry of the Suprarenal Gland." The latter subject was discussed quite extensively by Drs. Minehardt, Horn, Morgan, Addicks, Kendig, and Sajous.

March, 1910.—The stated meeting of the Branch was held on the 3rd of the month, President Blair presiding. After the dispatch of routine business, the election of officers for the ensuing year was held, which resulted as follows: Frank E. Morgan, President; R. W. Cuthbert, First Vice-President; F. E. Stewart, Second Vice-President; Ambrose Hunsberger, Secretary-Treasurer. The "Suggestions On the N. F." offered by Mr. England at the last meeting were then taken up seriatim and discussed. It was generally agreed that standards must be given in the N. F. if laws were to be enforced properly. Another point strongly urged was the need for co-ordinated effort on the part of the two committees which have in charge the revision of the U. S. P. and the N. F. The suggestion that the N. F. include deletions from the U. S. P. brought out the query as to the right of the N. F. to re-establish the legal standard of an article deleted from the Pharmacopoeia. Complex formulas, credited with therapeutic virtue and popular among a reasonably large number of medical practitioners, must be retained for working guides. Regarding the class of preparations generally referred to as "imitations," it is held that the physical characteristics of all the preparations in the N. F. should be such as to preclude any suspicion of attempted imitation. Postponing the further consideration of the suggestions to the April meeting, a resolution was adopted as the sense of the Branch: That in the preparation of the text for standards of the substances and their preparations in the new edition of the N. F., the general principles as adopted in the U. S. P. be followed. Those taking an active part in the discussions at this meeting included Messrs. Kraemer, England, Stanislaus, LaWall, Remington, Apple, Stewart, Riegl, Blair, Koch, Staudt, Stroup and Kebler.

The meeting of the Scientific Section of the Branch, which was held on March 10th, was devoted to a discussion of the subject of "Enzymes." The first paper was by Dr. Henry Leffman, in which he comprehensively described "The Nature of Enzymes." This was followed by a paper on "The Physiological Action of Enzymes," by J. W. England. L. H. Bernegau then made a preliminary report upon "The Inhibitory Action of Mechanical Agitation on Rennin," and Dr. Arthur C. Morgan ably discussed "The Therapeutic Uses of Enzymes." These several papers were fully discussed by Messrs. Remington, LaWall, Stanislaus, Leffmann, Ungerer, Turner, and others.

April, 1910.—The stated meeting of the Branch was held on the 7th of the month, President Morgan presiding. The first subject for considera-
tion was a draft of "The Declaration of the Prescription" agreed upon at a joint conference of a committee appointed by the Branch and a similar committee representing the County Medical Society, which was approved tentatively, final action being deferred until the County Medical Society has taken action upon it. The authorship of the form of this declaration (which see in A. Ph. A. Bulletin, June, 1910, 375-376) is credited to Mr. Franklin M. Apple. After a brief discussion of the crusade against the illegal sale of cocaine inaugurated by the State Association, and on matters of minor importance, Dr. F. E. Stewart introduced the set topic for the evening by reading a most comprehensive paper on "Patents and Trademarks in their Relation to Pharmacal Science and Practice," which is briefly reported in abstract in the A. Ph. A. Bulletin (June p. 377-378), and engaged markedly the attention and discussion during the remainder of the evening—Mr. Francis Taylor Chambers of the Philadelphia Bar in opening the discussion, paying a splendid tribute to the thorough manner in which Dr. Stewart had handled the subject. Other speakers were Dr. S. Solis-Cohen and Henry Bates, Jr. Professors Remington and Stanislaus, and the president of the Branch, Mr. Morgan.

May, 1910.—The last meeting of the season was held on the 17th of the month. The scientific program having been a part of a joint meeting held with the County Medical Society in April, there was little beside routine business to be taken up at this meeting of the Branch. After disposing of this, an interesting report of the A. Ph. A. Convention at Richmond was made by Mr. Franklin M. Apple, after which the meeting adjourned.

Pittsburg Branch.

January, 1910.—At the meeting of the Branch, held on the 8th of the month, the principal interest centered on three papers which were read after disposing of routine matters. Dr. Louis Emanuel read a paper entitled "National Formulary Vehiculae," in which he presented formulae for a new class of preparations for favorable recognition to the N. F. Committee. This paper appears in full in the A. Ph. A. Bulletin of February, 1910 (p. 125), and should be carefully perused. The second paper, entitled "The Prescription," was contributed by Mr. Peter G. Walter, and is commendable for the homely yet valuable truths and the light it threw upon the importance of commonplace details. The third paper was a valuable and well-prepared contribution concerning the "Hookworm, the Lazy Disease," by Leonard K. Darbaker. The several papers were discussed by Messrs. Beal, Pritchard and Willets.

February, 1910.—On the 8th of this month the Pittsburg Branch held its first annual meeting, the following officers being elected for the ensuing year: John C. Wallace, President; Louis Saalbach, First Vice-President; Richard Mierzwa, Second Vice-President; B. E. Pritchard, Secretary; P. Henry Utech, Treasurer. After the transaction of routine business,
the regular program of the evening was taken up. J. H. Wurdack read a paper on "Window Display," bristling with reproaches for carelessness and neglect, mingled with many ingenious and practical suggestions, both quaint and original. Louis Saalbach submitted a "Report of the Committee on N. F. Recommendations," to which had been referred a number of suggestions and criticisms. After considerable discussion two of the recommendations were adopted, viz.: (1) The Branch is opposed to dropping the preliminary notes preface various classes of preparations, and (2) that in the opinion of the Branch the introduction of more preliminary notes, rather than their deletion is desirable. A third recommendation, concerning the deletion of the formula for elixir of pepsin and bismuth, was referred for consideration at the next meeting. Mr. Geo. W. Kutzer opened a third subject, "Governmental Revision of the Pharmacopæia," taking the affirmative, while Mr. Louis Saalbach spoke in the negative. The contestants presented strong arguments on their respective sides, bringing forward many excellent arguments for and against the proposition, which are promised for publication at a convenient date, but no ballot was taken and the question at issue remains unsettled.

March, 1910.—At the March meeting of the Branch attention was directed to the fact that the Pittsburg Branch has no assessed membership, and that consequently the current expenses during the past year were covered by contributions from 21 of its "loving friends." Attention was also called to the failure of the various pharmaceutical journals to publish accounts of the meetings of the Branch, and it was suggested by President Wallace that the Publicity Committee seek to remedy this lapse on the part of the journals. The Program Committee then submitted the following papers for discussion: "One Year's Accomplishment of the Pittsburg Branch," by B. E. Pritchard; "What I Know About Finance," by P. Henry Utech; "A Few Observations on Soft Elastic Capsules," by Louis Emanuel, Jr.; "Physician, Pharmacist and Proprietaries," by A. H. Riehmumueller, M. D. These papers were read with one exception, that of Mr. Utech, who was unavoidably absent. The Program Committee submitted an interesting program for the April meeting of the Branch.

April, 1910.—The stated meeting of the Branch was held on the 12th of the month, the attendance being the largest in its history. The program submitted by the Committee for the evening's discussion was as follows: "Deceptively Advertised Proprietaries," by Dr. H. G. Blank; "The Relation of the Pharmacy Student to his Preceptor," by N. A. Grauer; "Some Pharmacy Not Taught in Our Schools," by P. Henry Utech; "A Forecast of the 1910 U. S. P. Convention," by Dr. J. H. Beal; "Symposium of Difficult Prescriptions" (with use of lantern slides), by Drs. Saalbach and Darbaker; "Moving Pictures Illustrating Industrial Scenes," by Dr. L. K. Darbaker. The different papers were well received and discussed after being read by Messrs. Beal, Utech, Willets, Kutzer,
Koch, Blumenschein, Emanuel, Holsopple, Wallace, Pritchard, and others. N. A. Grauer presented a voluntary paper upon the stability of some of the U. S. P. syrups, in which he recommended the elimination of sugar from the formula and replacing it with glycerin. A series of resolutions was presented from the City of Washington Branch with the request that they be endorsed by the Branch. On motion the matter was referred to the U. S. P. delegation.

**City of Washington Branch.**

*November, 1909.*—The stated meeting of the Branch was held on the 3d of the month, and was devoted entirely to a “Discussion of Patent and Trade-Mark laws.” The subject was introduced by Dr. Murray Galt Motter, who discussed the report of the Committee on Patents and Trade-Marks of the American Medical Association, pointing out that this report evidently written by some one thoroughly familiar with the several problems involved—presented the several questions in a clear and concise manner and was certainly well worth careful study on the part of everyone at all interested in the possibility of correcting the abuses that have developed out of the present laws as interpreted. Dr. F. E. Stewart, a member of the Committee referred to, in discussing the report of his committee presented some additional evidence in support of the conclusion therein presented. Mr. Samuel Hilton reported on the hearings on the “Mann Bill” and outlined its history, and Mr. Willard S. Richardson reported on the hearings that have been held on the “Currier Bill,” which he hopes to see enacted into law, believing it to be in every way just and equitable. The question was discussed from various points of view by other speakers: Dr. Worth Hale, Dr. William H. Leaman, Prof. John Uri Lloyd, Dr. H. W. Wiley, and Messrs. M. I. Wilbert and Wymond H. Bradbury, whose remarks may be consulted in the A. Ph. A. Bulletin of January, 1910, p. 10–12.

*December, 1909.*—The stated meeting, held on the 1st of the month, was devoted to a discussion of “The Report of A. Ph. A. Committee on National Formulary.” Mr. H. P. Hynson spoke of perfecting the N. F. and outlined what he believed that the book should be and what it should not be, as indicated in his letter to the Chairman appearing in the December Bulletin (pp. 472–474). Prof. H. E. Kalusowski, in his review of the report, commended many of the conclusions reached by the committee, mentioning in particular the objection to the deletion of certain introductory notes of instruction, but also directs attention to some oversights—such as misleading titles which would tend to bring the work of the Association into undeserved disrepute. Other speakers who spoke interestingly on the subject were Messrs. Augustus C. Taylor, Lewis Flemer, Lyman F. Kebler, S. L. Hilton, and H. W. Wiley, whose remarks are reported in the A. Ph. A. Bulletin of January, 1910 (pp. 12–16). Following
a suggestion made by Mr. Hynson, the president was on motion requested to appoint a committee of five to consider the several suggestions that were presented during the discussion and to report at the February meeting of the Branch. The following officers were then elected to serve for the year 1910: Samuel L. Hilton, President; Rodney H. True, First Vice-President; Henry E. Kalusowski, Second Vice-President; Miss Alice Henkel, Third Vice-President; M. I. Wilbert, Secretary; W. H. Bradbury, Treasurer.

January, 1910.—The stated meeting of the Branch, held on the 5th of the month, was devoted to a “Discussion of the Pharmacopœia of the United States,” the discussion being opened by the Chairman of the Committee of Revision, Professor Joseph P. Remington. Mr. Geo. M. Beringer, discussed the scope of the book, and calling attention to the report of the A. Ph. A. Committee on the U. S. P., pointed out that this report represented the individual views of the members composing that committee and that no attempt had been made to harmonize the views of the several members. Professor Henry Kraemer discussed the importance of pharmacognosy in connection with pharmacopœial work and pointed out that in the U. S. P. fully 70 per cent. of the articles are more or less intimately dependant on plant drugs. H. H. Bartlett in discussing the nomenclature of the Pharmacopœia pointed out the desirability of uniformity in the titles of medicaments which should be made universal for all pharmacopœias. Professor Remington, opening the general discussion, took up the subjects thus presented, and gave a very interesting talk on these and other matters concerned in the forthcoming revision of the U. S. P. He was followed by Dr. H. W. Wiley, Dr. Reid Hunt, and Prof. Kalusowski in an equally interesting view, as will appear on consulting the report of this meeting in the A. Ph. A. Bulletin of February, 1910 (pp. 85–89).

February, 1910.—The meeting of the Branch, held on the 2nd of the month, was in accordance with the resolution at the December meeting devoted to the discussion of the “Report of a Special Committee on National Formulary.” This report, as presented by the Chairman of the Special Committee, Mr. Lyman F. Kebler, appears verbatim in the A. Ph. A. Bulletin of March, 1910 (pp. 144–148), and should be consulted for the proper understanding of the several propositions acted on and endorsed at this meeting, which are here reproduced in full, as principles that, in the opinion of the City of Washington Branch, should govern the revision of the National Formulary:

Object.—The National Formulary should be a book of remedies which not only conserve and protect the welfare of the people, but also represent the best that the American Pharmaceutical Association stands for.

Nomenclature.—No name should be used which misleads in any particular.

Standards.—It is believed that it would be preferable to have a definite standard prescribed, when practicable, for each product recognized.
Division of Book.—It is unwise to divide the book into two parts.

Introductory Notes.—The National Formulary should include useful introductory notes, comments, etc.

Metric System.—The metric system alone should be employed in giving the quantity or proportion to be used in preparing the various products.

Medicinal Tipples.—All products which bear any form of stigma characterizing tipples should be eliminated.

Saccharin.—The use of saccharin as a sweetening agent for National Formulary products should be discouraged.

Pills.—The general direction for making and coating pills should be continued if it is found practicable to present the matter in an intelligible form.

Artificial Coloring.—The artificial coloring of official preparations should be discouraged; it is desirable, however, to introduce one or more formulas for preparing coloring solutions to be used when called for by prescriptions.

Preservatives.—Preservatives, other than such articles as alcohol and glycerin, should not be used in pharmaceutical preparations.

Basic Elixirs.—The introduction of several select basic elixirs is recommended.

Proprietary Medicines.—Formulas intended to produce an imitation of some proprietary product should not be included in the National Formulary.

Supplements.—Supplements, corrections and additions should be issued as the progress of pharmacy and medicine may demand.

The following recommendations were not concurred in by the majority of the members present, either because of a difference of opinion or because the subject matter itself has, as yet, not been sufficiently well discussed to permit of the expression of a definite opinion by many of the members present.

Synonyms.—The Committee believes that there should be introduced into the National Formulary as many synonyms as possible for the several preparations.

National Formulary a Book of Formulas.—The Committee is of the opinion that all simples should be embodied and described in the Pharmacopoeia and that all mixtures and composites such as “Vegetable Cathartic Pills,” “Compound Tincture of Cardamon,” etc., should find a place in the National Formulary.

Druggists’ Receipt Book.—The Committee expressed the belief that the only good purpose that such a book could serve is that of a repository for worthless, antiquated and defunct products. It is unable to see what possible value such a book would be to the progressive pharmacist.

Extemporaneous Preparations.—The Committee itself was undecided as to the advisability of preparing the various N. F. products extemporaneously, but expressed the opinion, evidently the majority, that it is the safer procedure to dilute fluidextracts with an appropriate solvent in the manufacture of a tincture than to prepare such tincture under conditions which are not as favorable as they might be.

Additions and Omissions.—The Committee believes that great liberality should be exercised along these lines because the National Formulary is to be used by people located in various sections of the country.

In view of the apparent difference of opinion regarding the possibility of harm resulting from “the use of saccharin,” a resolution was passed to refer the matter to the Surgeon General of the Public Health and Marine Hospital Service with the request that it be made the subject of pharmacologic investigation.

March, 1910.—The stated meeting of the Branch, held on the 2nd of the month, was devoted to the discussion of subjects relating to “The
Forthcoming Revision of the Pharmacopoeia.” Dr. G. A. Menge discussing “The Melting Points” directed attention to some of the causes of divergence in melting-point determinations and suggested that in place of determining the melting “point” it would be better for the Pharmacopoeia to direct that the range of melting be noted, as it is practically impossible to accurately define any one point in which all observers would agree. Dr. Atherton Seidell discussed “Solubility Factors” which have become more important with the acceptance of the Pharmacopoeia as a legal standard. He discussed the general subject of solubilities and outlined the possible uses to which accurate information regarding this factor might be put. Dr. Norman Roberts pointed out that despite the fact that the U. S. P. requires about 54 of the official liquids to be “colorless,” it is well known that such a thing as a “colorless liquid” does not exist in fact. Dr. Lyman F. Kebler, discussing the subject of “Hydrogen Dioxide,” asserted that the points made by the previous speakers while interesting were important only from a theoretical point of view. The troubles that had been encountered by him were real, as explained in the course of his further remarks, leading to further discussion by a number of members and visitors present. An interesting criticism and review of the recommendations of the Branch Committee on the National Formulary was received from Mr. Otto Raubenheimer, in which he expressed his personal views on a number of questions not endorsed at the February meeting of the Branch, which may be consulted in the A. Ph. A. Bulletin (April, 1910, 214).

April, 1910.—The stated meeting of the Branch this month was devoted to the discussion of suggestions for general principles to be followed in revising the Pharmacopoeia of the United States, and resulted in the adoption, without a dissenting vote, of the following resolutions defining what in the opinion of the Branch should constitute the function and scope of the work; these to be submitted to the Pharmacopoeial Convention;

Whereas, It has been recommended that the Pharmacopoeia of the United States be recognized and used as the basis for medicinal prescribing; and

Whereas, It has been recommended that medical colleges use the Pharmacopoeia as a text-book, or book of reference for students; now, therefore, be it

Resolved, That the Pharmacopoeia should be a compilation of the acceptable standards for desirable medicaments of known and recognized value; and be it further

Resolved, That the United States Pharmacopoeial Convention, to be held in Washington, May 10, 1910, be requested seriously to consider the adoption of the following rules for general principles to govern admissions to and deletions from the Pharmacopoeia of the United States.

1. That drugs which possess no well-recognized medicinal value be not included in the U. S. P.

2. That the duplication of drugs having essentially the same medicinal action be discouraged.

3. That drugs which are fully represented by an official active principle be omitted from future editions of the U. S. P.
4. That substances which are of but secondary importance as drugs and are used primarily as foods be not retained.
5. That whiskey and alcoholic beverages be deleted from the U. S. P.
6. That substances which have no direct therapeutic value and are used as solvents or reagents be included in the appendix.
7. That the unnecessary duplication of Pharmaceutical preparations such as wines, vinegars, tinctures and fluidextracts of the same drugs be discouraged.
8. That the continuing of fixed formulas for complex mixtures be discouraged.
9. That all formulas for preparations that can be made extemporaneously be recommended for admission to the National Formulary.
10. That all complex preparations not provided for by international treaties be relegated to the National Formulary.
11. That further efforts be made to establish and adopt international nomenclature and standards for drugs and preparations.
12. That compounds and mixtures permanently controlled either by secrecy or proprietary rights be not admitted to the U. S. P.

In the course of the discussion preceding the adoption of the above resolution, attention was called to a number of communications, which had been received, bearing on these resolutions, and that many of these, coming from representative individuals, were in harmony with the resolutions adopted by the Branch. Those participating in the discussion during the meeting were: Messrs. Murray Galt Motter, Reid Hunt, M. F. Finley, M. I. Wilbert, W. M. Barton, L. F. Kebler, Drs. Magruder and Seidell, Prof. Kalusowski and Mr. Flemer.

PROCEEDINGS OF STATE PHARMACEUTICAL ASSOCIATIONS 1909.

In the following no attempt has been made to give a synopsis of the proceedings of the State Pharmaceutical Associations. It is confined to the dates of the meetings, the names of the executive officers and to the titles of the original papers read, with the names of their authors, in accordance with information gathered from the official proceedings that have been received by the reporter. It may be noted that less than one half of the State Associations have complimented this Association with their printed proceedings of meetings held during 1909. Note also, that the papers marked with an asterisk (thus *) have been abstracted for this report.

Alabama.—The Twenty-Eighth Annual Meeting of the Alabama Pharmaceutical Association was held at Gadsden, June 9 and 10, 1909. Lee Whorten, of Gadsden, was elected President; W. E. Bingham, of Tuscaloosa, Secretary.

The following papers were presented at this meeting:
"How to Bring the Druggists Closer Together," by Mrs. J. T. Roe.

"The Doctor and Proprietaries," by Dr. Murphree.

Arkansas.—The Twenty-Seventh Annual Meeting of the Arkansas Association of Pharmacists was held at Pine Bluff, May 11, 12 and 13, 1909. O. O. Lumpkin, of Pine Bluff, was elected President; Miss Mary A. Fein, Secretary-Treasurer.

The following papers were read at this meeting:

"Wild Cherry Bark," by Henry Weimar.

"Syrup Phosphates Compound, N. F. (Chemical Food)," by A. C. Parse.

"Are We as Pharmacists Doing Our Duty in the Prevention of Tuberculosis?" by Dr. Eugene Winkler.

Connecticut.—The Thirty-third Annual Meeting of the Connecticut Pharmaceutical Association was held at New Haven, June 15 and 16, 1909. Patrick J. Garvin, of Bethel, was elected President; John B. Ebbs, of Waterbury, Secretary.

The following paper was read:

Illinois.—The Thirtieth Annual Meeting of the Illinois Pharmaceutical Association was held at Quincy, June 15 to 17, 1909. W. D. Duncan, of Ottawa, was elected President; W. B. Day, Chicago, Secretary.

No individual papers were presented at this meeting.

Indiana.—The Twenty-eighth Annual Meeting of the Indiana Pharmaceutical Association was held at French Lick Springs, June 22 to 24, 1909. Burton Cassaday, of West Terre Haute, was elected President; Maurice P. Schwartz, of Indianapolis, Secretary.

The following papers were read at this meeting:

"The Pharmacist as a Citizen," by Dr. J. N. Hurty.

"Legislation," by J. M. Barrett.

"Recreation—Does the Druggist Need it?" by J. R. Mutz.

"The Practical Operation of Soda Fountains, With Reference to Syrups, Crushed Fruits and their Preparations," by Prof. H. E. Barnard.

"Random Thoughts," by Leo Eliel.

Kansas.—The Thirtieth Annual Meeting of the Kansas Pharmaceutical Association, was held at Independence May 25, 26 and 27, 1909. A. E. Topping, of Overbrook, was elected President; Robert Lowman, of Pittsburg, Secretary.

No individual papers were presented at this meeting.
Kentucky.—The Thirty-Second Annual Meeting of the Kentucky Pharmaceutical Association was held at Cerulean Springs, June 15, 16 and 17, 1909. George L. Tenny, of Stanford, was elected President; J. W. Gayle, of Frankford, Secretary.

The following papers were presented at this meeting:

"Should Druggists Discourage the Sale of Morphine, Cocaine, Opium and their Derivatives?" by William J. Johnston.

"Collection of Odd Orders and Remarks on Same," by Marvin D. Averill.

"Should Our State Pharmacy Law Be Repealed, and Should we have Registered Assistants and Apprentices Incorporated in a New Measure?" by J. W. Gayle.

"The Directoire Gown," by Mrs. Dr. Leathers.

Maine.—The Forty-Second Annual Meeting of the Maine Pharmaceutical Association was held at Portland, June 29 and 30, 1909. John Coughlin, of Augusta, was elected President; Dr. M. L. Porter, Secretary and Treasurer.

The following paper was read at this meeting:

"The Pharmacist and the Physician," by Dr. Horace Fox.

Minnesota.—The Twenty-Fifth (the Silver Jubilee) Annual Meeting of the Minnesota State Pharmaceutical Association was held at Tonka Bay, June 16, 17 and 18, 1909. A. D. Thompson, of Minneapolis, was elected President; Theo. F. Leeb, of Winona, Secretary.

The following papers were presented at this meeting:

"The New College of Pharmacy Building," by Frederick J. Wulling.

"The College of Pharmacy of the University of Minnesota—Historical. (An Annual Contribution, continued from 1908)," by Dean Wulling.

"The Proprietary" (so-called), by Theo. F. Leeb.

"Digitalis," by Edgar D. Brown, M. D.

Missouri.—The Thirty-First Annual Meeting of the Missouri Pharmaceutical Association was held at Joplin, June 15, 16, 17 and 18, 1909. W. K. Ilhardt, of St. Louis, was elected President; Henry M. Whelpley, Permanent Secretary.

The following papers were read at this meeting:

"Can Drug Store Hours be Shortened and Sunday Closing Extended?" two papers, by H. O. A. Huegel and by F. G. Uhlich.

"General Replies to Questions Submitted by Committee on Papers and Queries," by J. G. Geiwitz.

"Suggestions on Membership," by Charles E. Meyer.

"Suggestions Wanted for Our New Board of Pharmacy," two papers, by Francis Hemm and by H. W. Servant.

* "What Constitutes a Reputable College of Pharmacy from the Viewpoint of the Missouri Pharmaceutical Association?" by Leo R. Suppan.
* "The 1884 Meeting," by H. M. Whelpley.
* "Is Commercial Instruction in Our Colleges Doing Good?" by L. Liebersteim.

"The U. S. P. Alkaloids and Their Salts," two papers, by Francis Hemm and by William Mittelbach.
* "Cinchona Alkaloids," by H. M. Pettit.
* "Trade Interests," by W. F. Ittner.
* "Missouri Pharmacy Law," by A. Brandenberger.
* "Answers to Queries," by H. A. Kattelman.

New Hampshire.—The Thirty-Sixth Annual Meeting of the New Hampshire Pharmaceutical Association was held at The Weirs, June 29 and 30, 1909. Edwin M. Allen, of Canaan, was elected President; Herbert E. Rice, of Nashua, Secretary.

The following papers were read at this meeting:
* "What's the Matter with the Drug Business of To-day?," by Herbert E. Rice.

New Jersey.—The Thirty-Ninth Annual Meeting of the New Jersey Pharmaceutical Association was held at Lake Hopatcong June 9, 10 and 11, 1909. George H. Horning, of Roselle Park, was elected President; Frank C. Stutzlen, of Elizabeth, Secretary.

The following papers were presented at this meeting:
* "Capsella Bursa Pastoris," by Dr. P. Hommell.
* "Compound Tincture of Gentian," by B. Hulick.
* "Notes on Volatile Oils of the U. S. P.", by Chas. H. LaWall.
* "Plasters of the Pharmacopoeia," by F. B. Kilmer.
* "Should Phenolphthalein be Recognized by the U. S. P. as a Therapeutic Agent?," by Dr. P. E. Hommell.

REPORT ON THE PROGRESS OF PHARMACY.

* "The Rapidity of Volatilization of Camphor," by Chas. H. LaWall.
* "The Senna Syrups," by Dr. P. E. Hommell.

North Carolina.—The Thirtieth Annual Meeting of the North Carolina Pharmaceutical Association was held at Greensboro, June 23, 24 and 25, 1909. G. Y. Watson, of Southport, was elected President; P. W. Vaughan, of Durham, Secretary.

The following papers were read at this meeting:
"Answers to Queries," by William Niestlie.
"Drug Store Advertising," by —?

Ohio.—The Thirty-First Annual Meeting of the Ohio State Pharmaceutical Association was held at Cedar Point, July 13, 14 and 15, 1909. C. S. Ashbrook, of Mansfield, was elected President; Theo. D. Wetterstroem, of Cincinnati, Secretary.

The following papers were read at this meeting:
* "Alkaline and Antiseptic Solution," by H. V. Arny.
* "A Few Observations at the Prescription Counter," by W. Kaemerer.
* "Formaldehyde Tests," by George D. Beal.
"Pharmacy as a Science," by L. H. Witte.
"Should Drugs Furnished by Doctors be Required to Comply with Legal Standards?" by C. M. Shafer.

Pennsylvania.—The Thirty-second Annual Meeting of the Pennsylvania Pharmaceutical Association was held at Bedford Springs, June 22, 23 and 24, 1909. John C. Wallace, of New Castle, was elected President; Edgar F. Heffner, of Lock Haven, Secretary.

The following papers were read and presented at this meeting:
"Answer to Query 8 (Regarding the Lawful Use of Synthetics for Preparing Flavoring Extracts)," by Louis Saalbach.
"Concerning the Increase of Proprietary Preparations," by B. E. Pritchard.
* "Confirmation of Saccharin in Foods and Beverages," by F. A. Genth, Jr.
* "Fresh Belladonna Leafs," by J. G. Roberts.
* "Formulas for Some New Basic Elixirs," by George M. Beringer.

South Dakota.—The Nineteenth Annual Meeting of the South Dakota Pharmaceutical Association was held at Lead, August 18, 19 and 20, 1909. J. Deetken, of Deadwood, was elected President; E. C. Bent, of Dell Rapids, Secretary.

The following papers were read at this meeting:
“A Few Don’ts in a Drug Store,” by E. C. Bent.
“Why I Attend the Pharmaceutical Association,” by Mrs. D. F. Jones.
“The College Boy and His Relation to the Pharmaceutical Association,” by Prof. B. T. Whitehead.
“Should or Should Not a Druggist Allow a Patent Medicine Concern to Use his Name in Advertising their Nostrums?” by Julius Deetken.
“How Can Our Association Aid the Pharmacy Department at Brookings State College?” by James Lewis.
“What Are the Necessary Qualifications for an Ideal Prescription Pharmacist?” by C. L. Stillman.
“Of Interest to Physicians and Pharmacists,” by Dr. Waldron.

Tennessee.—The Twenty-Fourth Annual Meeting of the Tennessee Pharmaceutical Association was held at Sewanee, July 20, 21 and 22, 1909. W. I. Gates, of Whiteville, was elected President; E. F. Trolinger, of Nashville, Secretary.

The following papers were read at this meeting.
“The Practical Operation of Soda Fountains with Reference to Syrups, Crushed Fruits and Their Preparations,” by H. E. Barnard.
“Shorter Hours and Sunday Closing,” by W. I. Gates.
“Druggists’ and Doctors’ Relation, and What Should be Done by Each to Induce Harmony,” by O. J. Nance.
“School for Employees—Training Our Helpers,” by Iliff Conger.
“Excessive Prices on Proprietaries and How Best to Bring Them Lower,” by Ernest Finch.
“Druggists Making and Selling Their Own Preparations,” by George S. Alcorn.
Texas.—The Thirtieth Annual Meeting of the Texas Pharmaceutical Association was held at San Antonio, June 15, 16 and 17, 1909. R. H. Walker, of Gonzales, was elected President; E. G. Eberle, of Dallas, Secretary-Treasurer.

The following paper was read at this meeting:
“Some Clerks I Have Known,” by W. H. Cousins.

Vermont.—The Sixteenth Annual Meeting of the Vermont State Pharmaceutical Association was held at Lake Bomoseen (Castleton), June 22, 23 and 24, 1909. Arthur L. Cheney, of Morrisville, was elected President; W. E. Terrill, of Montpelier, Secretary.

The following papers were read at this meeting:
“Should the Druggist Handle Liquors When He Has the Legal Right to Do So, and How Does It Affect the Business?” by F. J. Kinney.

West Virginia.—The Third Annual Convention of the West Virginia State Pharmaceutical Association was held at Morgantown, June 3 and 4, 1909. Arch. Kreig, of Charleston, was elected President; F. S. Johnston, of Elkins, Secretary.

The following papers were read at this meeting:
“The Pharmacist vs. the U. S. Internal Revenue Department,” by B. E. Pritchard.

Wisconsin.—The Twenty-ninth Annual Meeting of the Wisconsin Pharmaceutical Association was held at Elkhart Lake, June 22 to 25, 1909. F. M. Charlesworth, of Kaukauna, was elected President; E. B. Heimstreet, of Janesville, Secretary.

The following papers were presented at the meeting:
“Druggists Versus Tuberculosis,” by Otto J. S. Boberg.
“Pharmacy, Commercial or Scientific,” by W. F. Kaiser.
“Should a Druggist Allow His Name to be Used in Advertising Patent Medicines?” two papers, by Fred. G. Wiechmann and by M. C. Trayser.
“Sunday and Early Closing,” by J. K. Stephany.
“The Help Problem and How to Solve It,” by Max R. Zaegel.
PHARMACY.

A. APPARATUS AND MANIPULATION.

Titration—Simple Device to Prevent Over-Titration.—In order to prevent over-titration in rapid work, F. Schulz places a piece of tube of 12 to 15 Mm. bore and open at both ends in the liquid to be titrated; this temporarily separates a portion from the reagent that is run in, and titration can be carried at once to a point at which the color is completely changed. By agitation the liquid in the tube is then mixed with the remainder, when the original color returns, and the few drops necessary to finish the titration are cautiously added.—Pharm. Journ. and Pharmacist, Febr. 12, 1910, 173; from Chem. Ztg., Nov. 9, 1909, 1187.

Burettes.—New Forms.—W. Meysahn has devised two new forms of burettes, constructed entirely of glass and possessing pronounced advantages in the arrangement for regulating the outflow, which are clearly depicted in the accompanying cuts. These burettes (Figs. 1 and 2) are distinguished from the ordinary form by having the outflow through an elongated conical glass stopper, accurately ground and fitted so as to protrude from the nether end of the glass burette tube, which is calibrated and graduated as usual. The stopper in Fig. 1 is perforated centrally from above towards the middle and the perforation is then deflected laterally, and from below upward to within a short distance of the downward perforation, and then also deflected laterally, the lateral openings thus produced being coincident with a groove cut into the wall of the burette-tube. For convenience in finger ing, the projecting end of the tapering stopper is slightly bulged out, the details being shown by Fig. 2. By a simple turn of the stopper a full flow from the burette may be established or it may be reduced to drops at greater or less intervals, or cut off completely. When empty, the stopper may be removed by reversing the burette and pressing upon it, and the instrument then conveniently and thoroughly cleaned. The second form is shown by Fig. 3. In this the glass stopper is not perforated, but is provided with a groove coincident to the lateral outlet attached to the body of the burette, as shown in detail by Fig. 4. To facilitate the finger ing of the stopper, a hard rubber disk is provided, which may be slipped over the stopper and removed again easily when it is necessary to cleanse the burette.—Pharm. Ztg., liv (1909), No. 64, 623, and No. 82, 812.

Pharmaceutico-Chemical Burette—An Instrument of Precision.—Gustav Müller supplies a new form of burette (shown by Fig. 5) which is intended particularly for pharmaceutico-chemical titration directed in the volumetric operations of the G. P., in which it is important that the end
BURETTES.

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

Burettes.
of the reaction can be determined with absolute precision. This burette is graduated with great accuracy, the upper, wider part of the tube into cubic centimeters, the lower, constricted part (having a total capacity of 1 Cc.) being divided into graduations of $\frac{1}{10}$ cubic centimeters. The zero is im-

**Fig. 5.**

**New Form of Burette.**

**Fig. 6.**

**Reservoir Burette.**
This First, in the burette, in the three-way by simple No. immediately tap the made to covered burette, presents 235-improvement by No. (above possible and pressuring on the sanitary having grinding, use a of reservoir Burettes An Fig. The right of the burette, having a globular reservoir blown at the top, as shown by a. The tap connecting the arm may be of two kinds: First, a hollow three-way tap set upright, as shown in b. In this case the tap itself forms the spout of the burette. Second, a three-way tap, shown in different positions, depending on the use, by c, d and e. This tap has one hole drilled right through and another drilled half-way through, leading into the first hole at right angles. If this one is used, the burette must be made with a spout, as shown by a, and this is considered preferable to the use of a tap only, as shown by b, for it is easier to titrate with a tap in the front than with one set between the two limbs of the burette. The tap is in position d when filling reservoir; in position e when filling the burette, and in position c when running off a titration, while all connections are shut off by turning the tap at an angle from the “on” position to the “off” position.—Pharm. Journ. and Pharmacist, Aug. 14, 1909, 235.

Burettes and Clamps—Improved Forms.—Dr. Bertheim has devised a new burette clamp, shown in the accompanying cut (Fig. 7), which presents the advantage that the entire scale is visible, no portion being covered by the clamp itself. The clamping is effected by applying the principle of the set-screw, a simple turn of which exerts the pressure on the verticle surface of the clamp necessary to hold the burette in position.

An improvement of the burette consists in its expansion near the top (above the graduation) into a bulb, flattened on one surface and frosted by grinding, so that characters may be written on it with a pencil. This improvement is plainly shown by (Fig. 8). Pharm. Ztg. LV. (1910), No. 13, 127.

Burette Holder—Convenient Form.—Kuntze has constructed a new and convenient form of burette holder (Fig. 9) by interposing the extensible arm A between the clamps holding the burette and the sliding clamp on the upright support. The utility of this device is obvious, since the position of the burette may be changed at will by drawing out or compressing the extensible arm. Pharm. Ztg. LIV (1909), No. 99, 975.

Hygienic Pipette—A Practical Construction.—Dr. Meysahn has devised the pipette shown by (Fig. 10) which presents a form commendable on sanitary and hygienic considerations. It consists of an ordinary pipette having a syringe-like extension fused to the upper extremity, which is pro-
vided with a close-fitting leather plunger by means of which the suction necessary to fill the pipette to the mark is effected. The device is protected by a German patent. Pharm. Ztg. LIV (1909), No. 82, 811.

Burette Holder.

_Spritz-Bottles._—Clamps for Securing Stopper. E. A. Schott recommends the device shown by Fig. 11 for securely holding the stopper in spritz-bottles, which he has found useful when operating with hot liquids.
or when it is desirable to run more than ordinary pressure for projecting the liquid. The illustration requires no further discription. Pharm. Ztg. liv (1909) No. 82, 811.

Solubilities of Official Substances.—Definition. M. I. Wilbert suggests

100 Cc. of solvent will dissolve:
100 Gm. or more of a—"very soluble" substance.
10 Gm. to 100 Gm. of a—"freely soluble" substance.
1 Gm. to 10 Gm. of a—"soluble" substance.
0.1 Gm. to 1 Gm. of a—"slightly soluble" substance.
0.01 Gm. to 0.1 Gm. of a—"very slightly soluble" substance.
0.001 Gm. to 0.01 Gm. of a—"nearly insoluble" substance.
Less than 0.001 Gm. of a—"practically insoluble" substance.

Exact information regarding solubilities, Mr. Wilbert states, could be tabulated in the appendix, as is done in the Belgium Pharmacopoeia. Proc. Penna. Pharm. Assoc. 1909, 332-333.

Quick Pressure Filter—New Form.—Albert Kahlert Co. supply an ingenious quick-pressure filter consisting of a hollow cylinder with numerous perforations, which in use are covered with filter paper, the method of applying the filter paper being shown by Fig. 12, of holding the filter in place by means of rubber bands by Fig. 13, and the filter in use by Fig. 14, all of which is quite simple and needs little explanation. The filter cylinder being in cylindrical funnel, the syphon-tube is inserted and held air-tight in the upper orifice of the filter-tube by means of a rubber stopper. Suction is produced by means of the bulb in the syphon-tube and a flow
of liquid from the container is then continuously established, the rate of flow depending on the rapidity with which the liquid passes through the filter, which, in turn, depends on the length of the syphon-tube. The advantages are obvious. Filtration goes on automatically and rapidly, the filter-paper is economically utilized, and there is no loss of liquid by evaporation.—Pharm. Ztg., lv (1910), No. 34, 346.

Continuous Filtration—A Home-made Device.—"A Reader" has devised a continuous filter which consists of an inverted "flower-pot" with a piece of muslin tied over the mouth and a rubber syphon tube attached to a section of glass tubing inserted by means of a perforated cork into the hole at the bottom of the pot. The arrangement is shown by Fig. 15. The syphon-filter rests in a funnel inserted into the mouth of a receiving bottle, and the flow of liquid having been started continues until the liquid to be filtered is exhausted by the syphon from the vessel containing it.—Drugg. Circ., Aug., 1909, 405.

Filtration through Wadding.—A Practical Suggestion.—Von Heygendorff observes that if cotton wool or similar material is employed as a filtering medium, a small wad is very apt to slip down into the tube of the funnel and make filtration very slow. This may be prevented by putting a small Gooch filtering cone in the funnel underneath the wad, but the latter is then rather apt not to fit closely to the funnel, but to become packed together in the cone and allow some precipitate to pass. Both
difficulties are overcome by using two Gooch cones, the wool being placed between them, and the upper one being larger and heavier than the lower. Pharm. Journ. and Pharmacist, Febr. 12, 1910, 173; Pharm. Chem. Ztg. Nov. 9, 1909, 1187.

Quick Filter Funnel.—Novel Modification.—Dr. E. Murmann has constructed a funnel for quick filtrations which obviates the necessity of the long constricted funnel tubes usually employed for accelerating the flow of filtrates. The device, as shown by Fig. 16 consists of a knee-shaped bend of the tube just below the cone of the funnel, which is so adjusted as to be cause a slight upward flow of the liquid during its passage from the filter. This causes the production of small air spaces and consequent suction, which very efficiently accelerates the flow of liquid. It is import-

ant that the upward incline in the knee shall be about and not exceed the inner diameter of the funnel tube. The device is patented in Germany. Pharm. Ztg. lv (1910), No. 21, 213.

Filter-Spiral.—A Substitute for the Hot-Water Funnel.—H. Stoltzenberg has devised and recommends the filter-spiral shown by Fig. 17, which is constructed of thin glass tubing, as a substitute for the usual hot-water funnel for the filtration of hot liquids. The spiral is suspended in a beaker into which it fits snugly, a plaited filter is introduced, and the hot liquid poured into the filter. Filtration proceeds rapidly without danger of cooling, the surrounding steam keeping both the spiral and the filter quite warm to the end of the filtration. Pharm Ztg. liv (1909), No. 64, 623; from Chem. Ztg. 1909, No. 81.
Funnels with Shoulder—A Useful Device.—Klimach & Co. have introduced funnels provided with a shoulder at the lower extremity of the cone, which holds them rigidly in an upright position when introduced into the mouth of bottles or jars. They are constructed of tinned iron (Fig. 18) and glass (Fig. 19) and require no further explanation.—Pharm. Ztg., liv (1909), No. 91, 900.

Perforated Funnel Cone—Construction of Porcelain.—Dr. Rewald has introduced the perforated porcelain funnel cone, shown in its application by Figs. 20 and 21. The cone is flanged outwardly at the upper ex-
tremity and provided near the pointed extremity with three projections which insure its position from contact with the walls of the funnel into which it is fitted. The utility of the cone, which may be used for ordinary filtrations (Fig. 21) or for suction filtrations, is obvious. In either case, the filter-paper is introduced smoothly into the cone, but in operations with the suction pump the cone is fitted with a rubber ring at the upper extremity, as shown by Fig. 20. The collection and washing of precipitates, however dense or heavy, is greatly facilitated by the intervention of these cones, and ordinary filtrations are greatly accelerated.—Pharm. Ztg., liv (1909), No. 99, 976.

**Bung-Funnel.**—**Practical Construction.**—Aug. Wohlfart has devised and supplies the convenient contrivance shown by Figs. 22 and 23, which has proven very serviceable for filling and emptying barrels through the bungs into which, owing to its conical form, it is easily adjusted irrespective of variations in size. These funnels are constructed of zinc or other desirable metal, and are provided either with a partial jacket or enclose an air tube so that in filling air may pass out, and in emptying air may enter without bubbling through the liquid or spurting. Pharm. Ztg. liv (1909), No. 82, 812.

**Carboy Nozzle.**—**A Practical Device.**—Schmidt and Brösel supply a new carboy nozzle which serves admirably for emptying acid carboys of their contents without danger from spurting. As shown by Figs. 24 and 25 it consists of a cap, the part A (Fig. 24) being of soft, elastic rubber, while the extremity of the cap, composing the nozzle, is constructed of hard rubber, and bears a hard-rubber bent tube which extends well into the neck of the carboy-bottle and admits the air necessary to replace the space of the overflowing acid. Pharm. Ztg. lv (1910), No. 40, 409.
Syphon-Funnel—Convenient form for Decantations from Precipitates.—Dr. Ernst Richter calls attention to the tie-over funnel shown in outline by the accompanying drawing (Fig. 26), which, when the mouth is tied over with a suitable filter material (such as a four-fold layer of gauze), affords an efficient attachment to the syphon used for decantation from precipitates—such as ferric hydroxide, for example. The funnel is attached by means of rubber tubing to the short limb of the syphon, the long limb of which is provided with a rubber extension and pinch-cock—the short limb being adjusted by the aid of a clamp sliding on a vertical rod and held in place by a set screw. The use and method of application is obvious. When the liquid has been decanted to within 1 cm of the precipitate, the syphon is closed at the long limb, and the fresh wash water is added without removing the syphon, which is again ready for action when the precipitate has settled sufficiently.—Apoth. Ztg., xxiv (1910), No. 92, 871.

Syphons—Construction on a New Principle.—E. Neugebauer describes two forms of syphons which are constructed on an entirely new principle, as shown by Figs. 27 and 28. The glass syphon (Fig. 27) is composed practically of two syphons, $b\ a\ c$ and $b\ d\ e$, which are joined at $b$, and it functionates on immersing the smaller of the two ($b\ d\ e$) completely into
and beneath the surface of the liquid (f) in consequence of the vital force imparted to the fluid by its downward passage from d to b. This vital force is further augmented by lengthening the tube d b, and also by increasing the diameter of the same, as shown by Fig. 28, in which the greater diameter of the smaller syphon increases the lifting power and rapidity of outflow very materially. The only essential condition is that the smaller syphon shall be completely covered by the liquid in starting the operation. If it is desirable to facilitate the removal of the filled syphon, the end of e should be bent upwards.—Pharm. Ztg.

Safety Siphon—Efficient Construction.—Dr. Matton has devised the siphon which efficiently prevents the suction of liquids into the mouth and

![Syphons](image1)

![Safety Siphon](image2)

has proven particularly useful in separating two different fluids from each. The construction is plainly shown by Fig. 29, and needs little description. The siphon is filled by suction at B, the glass cock at the long limb being closed. As soon as the ball in the suction attachment is filled, the float within the ball closes the orifice with an audible click. Suction is at once suspended, and on opening the cock the liquid siphons off with a speed which is easily reduced to a minimum by manipulating the cock. This serves also for the separation of the two liquids conveniently if for any reason both liquids should be drawn into the siphon.—Pharm. Ztg., lv (1910), No. 21, 213.

Extraction with Immiscible Solvents—Apparatus Adapted for the Purification of Ether.—Rudolpho Fritsch, with such simple appliances as are
usually found in well-appointed laboratories, constructs an apparatus for the extraction of igneous liquids with immiscible solvents, which is shown in the accompanying drawing (Fig. 30). It consists of a flask (A) for the reception of the volatile solvent (ether), an inverted, two-necked Woulf’s bottle (B) for the reception of the liquid to be extracted, and a reflux condenser (C), which are connected in a suitable manner by means of glass tubes. The heat of a water-bath being applied to the flask, the ether vapor passes at (b) into the Woulf’s bottle, permeates the aqueous liquid in a finely divided state and, as it circulates on the top of the liquid, re-

![Fig. 30.](image)

Apparatus for Purification of Ether.

...turns through (a) into the flask loaded with the dissolved matter, to be vaporized as before until the aqueous liquid is considered to be completely extracted.

The apparatus, however, is particularly adapted for the purification of ether (removal of alcohol) by means of calcium chloride solution, now commonly used for this purpose—the alcohol being completely retained by the solution and pure ether accumulating in the flask.—Pharm. Ztg., liv (1909), No. 64, 623; from Chem. Ztg., 1909, No. 83–84.

*Extraction of Liquids with Immiscible Solvents—Efficient Form of Apparatus.*—Lind has devised a new form of apparatus for the extraction of liquids by the so-called “perforation method” with ether, which is illus-
EXTRACTION WITH IMMISCIBLE SOLVENTS.

47

trated by the accompanying cuts (Figs. 31 and 32). The flask (a—Fig. 32) contains the ether, or other immiscible volatile solvent, the vapor of which passes through the tube (c) into the extraction apparatus (b) and thence reaches the condenser (d). Here it is condensed and drops into the cup (g), from which it flows through the small hole (h) into the hollow spindle (e, e) of the stirrer and is ejected through openings in the hollow rings (k and i) at the bottom of the apparatus into the liquid to be extracted. The spindle (e) being revolved rapidly on its axis by the pulley (f), the solvent is mixed in a finely-divided state with the liquid to be extracted, and when sufficiently accumulated flows back into the flask through the tube (c), whence it again returns as vapor until the extraction is completed. Obviously, a number of these apparatus can be arranged side by side and several operations conveniently conducted at the same time.—Pharm. Ztg., liv (1909), No. 64, 622.

Extraction with Immiscible Solvents.—Convenient Apparatus.—Hermann Emde describes the simple apparatus shown by Fig. 33 which permits the automatic extraction of specifically heavier liquids with small quantities of specifically lighter immiscible solvents. An ordinary cylindrical separatory funnel is provided with an S tube, (C and C'), which may be attached by means of rubber-tubing and held in place by means of

Fig. 31.

Fig. 32.

Apparatus for Extraction of Liquids.
The stop cock \((b)\) being closed, a quantity of the immiscible solvent is introduced into the funnel and the heavier liquid to be extracted is allowed to drop in slowly in the smallest possible drops—the flow being regulated by means of a screw-clamp at \((d)\), observing that the point of the pipette-tube \(e\) just dips beneath the extracting solvent. When the heavier liquid has accumulated sufficiently to fill the \(S\) tube \((c c')\) the stop cock \((b)\) is opened and the extracted liquid will then flow out at \(c\) as fast as it drops into the separatory through \(e\). If desirable the liquid from \(c\) may be dropped into a second extraction apparatus charged with the same solvent, and this with a third, so as to secure complete extraction. But in any case, the apparatus and method secures the extraction of small quantities of substances from large quantities of specifically heavier liquids with the smallest possible quantity of the lighter immiscible solvent. Apoth. Ztg. xxiv. (1909), No. 72, 663.

Maceration and Percolation—History and Comparative Value.—Otto Raubenheimer has contributed an exceedingly interesting historical account and criticism on the comparative value of the processes of maceration and percolation for the extraction of drugs which must be consulted in the original to be fully appreciated. In his conclusion Mr. Raubenheimer says that in his experience the percolation process, and especially the improved macero-percolation method of the U. S. P., VIII, although the same cannot be used for the exhaustion of all drugs, decreases the

![Extracting with Immiscible Solvents.](image-url)
labor and saves time and is a scientific method par excellence. When properly carried on all the advantages of maceration are obtained, and furthermore it is superior to maceration, inasmuch as no strong menstruum is retained in the marc.—Amer. Journ. Pharm., Jan., 1910, 32-42.

Maceration and Percolation—Historical Review.—At the monthly meeting of the Kings County Pharmaceutical Society, Feb. 8, 1910, Thomas J. Keenan presented a highly interesting contribution to the study of maceration and percolation, in which he traces the history of percolation from the time when, during the early part of the eighteenth century, Edward Lloyd, a coffee-house keeper in Abechurch Lane, London, made his coffee by percolation, to the most recent utterances on the subject of drug extraction, incited by the prophetic words of Professor Tschirch, the eminent Swiss pharmacognostist, that he could foresee a time when medicine having thoroughly ruined its digestion with synthetical remedies, and tested all the organs of the animal body, “it (medicine) would return once more to the most ancient remedies of mankind—to the medicinal plants and drugs, for the utility of which the experience of thousands of years vouches.” Mr. Keenan’s paper must be read in the original, which appears in Amer. Drugg., Feb. 14, 1910, 73-76.

Extraction Apparatus—Simple Form.—Dr. A. Trager recommends the extraction apparatus shown by Fig. 34 as an efficient substitute for the Soxhlet apparatus, which may be cheaply constructed and requires little explanation. It consists of a glass cylinder, constricted below so as to form a tubular neck and enclosing a thin glass tube, bent to conform to the shape of the cylinder, through which the vapor reaches the reflux condenser (not shown) and returns through the material to be extracted, enclosed in a cartridge in the usual way.—Pharm. Ztg., liv (1909), No. 99, 975.

Dunstan and Short’s Extraction Apparatus—Simple Modification.—In order to avoid the lifting up of the column of drug and consequent liability of breaking up and being carried over into the outer tube during extractions with Dunstan and Short’s apparatus, P. É. F. Perrédés has devised the expedient shown in the accompanying cut (Fig. 35). This consists essentially of a spiral
spring of brass wire, soldered to a brass-ring above and to another below, but covered with coarse wire gauze, which is inserted into the inner tube so as to press lightly on its contents, and is held in place by a cork inserted in the upper aperture of the outer tube. The details of filling the inner tube, whereby the removal of any small particles from the column of drug is prevented, are visible in the illustration from below upward: A loose plug of glass wool; a layer of clean silver sand about a quarter of an inch thick; the column of drug; a layer of silver sand; a plug of glass wool—the last two similar to those below.—Pharm. Journ. and Pharmacist, Jan. 29, 1910, 106.

Hot Percolation—Advantage for Watery Extractions.—A. Astone com-

municates the results of experiments which convincingly point out the advantage of hot percolation over all other methods for the extraction of drugs with water. For this purpose he employs a double-walled or jacketed percolator, in which water may be kept at or near the boiling tem-
thermometer, and thus permits extraction with boiling water in a simple and expeditious manner.—Pharm. Ztg., lv (1910), No. 11, 107; from Journ. de Pharm. et Chim., 1910, No. 2.

Rigid Percolator Stand—A Practical Idea.—John J. Stephenson constructs the rigid percolator stand shown in the accompanying cut (Fig. 36) from two lengths of gas pipe, 12 and 36 inches in length respectively, each threaded at both ends, one end of each screwed into a socket with four screw holes, the other ends united with an elbow fitting. The socket of the longer limb is screwed to the work-table and that of the short, horizontal limb against the wall or shelf-front. Suitable rings, such as are on an ordinary retort stand, are then provided, of which various styles are obtainable from most dealers in chemical apparatus. The kind having the ring separate from the clamp, and the clamp having two thumb-screws, one for fastening to the upright, the other to hold and permit the extension of the arm to which the ring is attached, are the most suitable.—Bull. Pharm., March, 1910, 121.

The U. S. P. Melting Points—Causes of Divergence and Their Remedy.—In a paper read before the City of Washington Branch of the Association (March 2, 1910), G. A. Menge points out the cause of the divergence in the melting points given in the U. S. and other pharmacopoeias, which in essentials he summarizes as follows:

1. The great variety of methods used in melting-point determinations.
2. Varied individual manipulation, including the "personal factor," and especially the rate of heating.
3. Difference in the physical condition of the compounds.
4. The use of thermometers widely differing in their construction or range, or both.
5. The application or omission of emergent-stem correction and the manner of making it.

5. Widely varying interpretations of just what the melting point is (which might be considered to include the apparent use of decomposition point as equivalent to melting point).

The author discusses these different causes of divergence in the sequence given, in order to indicate the remedy to a greater or less degree, and mentions in conclusion of his very interesting paper, that its subject, and the work that has recently been done in the Hygienic Laboratory, U. S. Public Health and Marine-Hospital Service, will be given more complete and detailed treatment in a Bulletin to be published in the near future.—Amer. Journ. Pharm., April, 1910, 178-187.

Thermometer for Determining Melting Points—New Construction.—J. Bredt has devised and patented a thermometer for melting-point determinations which presents certain advantages over those usually employed for this purpose. The device consists of an expansion of the outer
thermometer tube, immediately below the graduation, having four longitudinal depressions or channels, as indicated by the cross-section a in the accompanying cut (Fig. 37), which are intended for the reception of the capillary tubes containing the substance to be tested, this arrangement being plainly shown in the cut of the entire apparatus. When the melting-point is to be determined in an air bath (as shown in the cut), these capillary tubes are fastened to the thermometer by means of thin platinum wire; but when a liquid bath, such as conc. sulphuric acid, paraffin, etc., is used, these tubes maintain their position by simple adhesion.—Pharm. Ztg., lv (1910), No. 30, 305.

Melting-point Apparatus—Simple Device.—Dr. Th. Weyl has devised the simple apparatus for melting-point determinations shown by Fig. 38.

It consists of three different parts: (1) A thermometer with the outer tube
Slightly bulged immediately above the mercury bulb; (2) a glass slide, fitting over the thermometer tube and provided with two sets of rings, the one superimposed over the other so that the opening in the upper ring coincides with that in the one beneath, and (3) the melting tubes, which, diminishing slightly in diameter downward, are held securely in position by the two rings, the openings of which are correspondingly different in diameter.—Pharm. Ztg., lv (1910), No. 40, 408; from Chem. Ztg., 1910, No. 55.

Home made Still—Construction from a Wash Boiler.—A. R. Eberle constructs a modified Remington still from an ordinary copper wash-boiler by fitting it with a deep rim into which the lid fits, and attaching an elbow at the center of the lid, of such size that it may be connected with the condenser of a Remington still. A screen on legs nine inches long is provided which fits into the kettle, and serves a good purpose for recovering alcohol from dregs. These are placed on a moistened cloth covering the screen, and heat being applied the steam from water under the screen carries over the alcohol. Among other operations for which this still has proven useful, it serves excellently for preparing distilled water, ten gallons being obtainable during a working day with one charge of the apparatus. When so used, the space in the lid above the rim is filled with a lot of plaster of Paris and linseed meal.—Proc. Wisc. Pharm. Assoc., 1909, 66-67.

Spectral-Attachment for Bunsen Burners.—A Simple Device.—Prof. H. Precht has originated and employs the simple device shown by Fig. 39, which when inserted into the tube of a Bunsen burner facilitates the ordinary flame tests and is particularly advantageous in spectral operations requiring the prolonged production of colored flames. It is constructed of a short section of brass tubing, split so as to give it the effect of a spring, to which a segment of iron wire bearing a small iron cup is soldered. The upper part of this wire and the little cup may, if desirable, be also constructed of platinum. The brass tube, acting as a spring, retains its position within the burner tube at any height, and this permits the adjustment of the cup containing the substance to be examined in any part of the flame that is desirable. The wire is so bent that the position of the cup is always coincident with the axis of the flame. Pharm. Ztg. lv (1910), No. 13, 128.
“Steady” for Evaporating Dishes—A Good Suggestion.—Having among a number of new porcelain evaporating dishes one that proved exception-ably “wobbly,” Emil Reger had a tinner make a ring of galvanized iron of suitable dimensions—in this case 1½ in. high and 6 in. diameter—

![Evaporating Dish](Fig. 40)

which proved an excellent support for steadying the dish during evapora-
tions over the open flame or other operations for which the dish may be used. The accompanying cut (Fig. 40) is self-explanatory.—Bull. Pharm., Jan., 1910, 28.

Oil-Bath—Useful Composition.—Louis W. Bosart, Jr., finds a mixture of 10 parts of refined cotton-seed oil and 1 part of beeswax to make a very satisfactory oil-bath. It emits very little fume below 250° C., and can be used safely almost throughout the range of the ordinary mercury thermometer, having a flash-point above 300° C. when heated in an open cup. A sample of hard paraffin under the same conditions flashed at 215° C. The mixture has the advantage of the paraffin-bath that it solidifies on cooling, so that there is not the liability of the oil spilling out when not in use, and it has the added advantage that it melts quickly.—Chem. News, Nov. 12, 1909, 238; from Journ. Amer. Chem. Soc., 31, No. 6.

Crucible Support—A Practical Device.—Carl Bormann describes the crucible support shown by Fig. 41, which offers some practical advantages. It consists of two small rings of different size, the larger superimposed above the smaller and having three movable porcelain holders attached which rest loosely upon the lower and smaller ring. By raising or lowering the smaller ring the points of the porcelain supports spread out or close upon each other, and in this way accommodate larger or smaller crucibles, which are held securely by the three points suspended from the upper
MECHANICAL STIRRER.

55

Universal Tripod—A Convenient Device.—Fleissner has devised a new form of tripod, the construction of which permits its use in various ways.

FIG. 41.

FIG. 42.

Crucible Support.

Universal Tripod.

It consists of the usual ring, but the legs are hollow and are provided with thumb-screws. As shown in the drawing (Fig. 42) this arrangement permits of the insertion of rods bearing clamps for holding burettes, flasks, etc., and the rods may be fixed at any suitable height and thus used for holding rather complicated apparatus.—Apoth. Ztg., xxiv (1909), No. 67, 602.

Mechanical Stirrer.—Novel Construction.—Douglas H. B. Couman has devised a mechanical stirring apparatus which is rapidly rotated by a jet of steam generated in a copper boiler of 1 liter capacity and is efficient in a solution containing 50 per cent. of sugar. The apparatus, as shown by Fig. 43, consists of a cylindrical copper flask (A) to which two brass tubes (B and C), 20 cm. long are soldered, and these support a piece of wide brass tubing (D) which is fitted with a cork through which a glass collar (E) is vertically fixed. The stirring rod (F), enlarged to a smooth disc (G) is slipped through the glass collar and than bent as shown at H. On the apex of the stirring rod a circular cork (K, 5 cm. in diameter and 1 cm. thick, is fitted, and this carries a number of vanes of zinc plate \( \frac{1}{2} \) Mm. thick and projecting from the cork about 1 sq. cm.—these vanes being inserted into slits made with a razor, and placed about 1 Cm. apart around the circumference, at an angle of 50° with the vertical, so that the steam from the glass pipe (M) will exert a lifting as well as rotating force, the diminishing friction at G. The string (N) holds the glass jet in a slightly

*Porcelain Mortars—Special Advantage.*—P. I. Minton observes that in titrating salol, veronal, or duotal in a glass or Wedgwood mortar, the mortar becomes electrified and the fine powder adheres to the sides, making it almost impossible to get it all out with a spatula. He finds that porcelain mortars do not become electrified under these conditions, and therefore always uses them when such substances require trituration. If porcelain mortars are not available the addition of one or two drops of alcohol to the powder will prevent it from adhering to the sides.—Bull. Pharm., Nov., 1909, 472.

*Mortar Rack—Convenient Device.*—Finding it hard to pick out the right mortar when they are either on a shelf or in the drawer, Lawrence Prudhome constructed the rack for their reception shown by Fig. 44, which supports the mortars well and has proven a great convenience. The required number of holes are cut into a soft piece of pine board to accom-
modate the different mortars, observing that these holes are a little larger than the bottom of the mortar. Small holes are also bored for the reception of the pestle belonging to the mortar, but care must be taken that the holes for mortars or pestles are not too big.—Bull. Pharm., Feb., 1910, 75.

Universal Laboratory Rack—Useful Construction.—Dr. Kehler has devised and patented (in Germany) the laboratory rack shown by Fig. 45, which is constructed of tinned wire, and commends itself by its compactness, accommodating in a small space 80 test-tubes, besides a number of

![Laboratory Rack](image-url)

**FIG. 45.**

Erlenmeyer and other flasks, together with pipettes, thermometers, funnels, etc., ordinarily required in the experimental laboratory. It has the further advantage of being easily cleaned, and rests firmly on the table.—Pharm. Ztg., lv (1910), No. 30, 305.

Test-Tube Rack—Convenient Construction.—M. Sollenberger constructs a cheap, convenient and stable test-tube rack by removing the top and one of the sides of a wooden box, say about 10 x 6 inches square and 7 inches high, the sides about $\frac{3}{4}$ inch thick, and screwing on the inner sides.
as shown in the drawing (Fig. 46), a row of corkscrews (of the style shown) about an inch from the bottom and another row four inches above, taking care so that the rings of the two rows be coincident. The size of the rings and rack depends on that of the test-tubes in use.—Bull. Pharm., Jan., 1910, 28.

Pharmaceutical Glass Ware—Alkalinity.—Dr. C. Jacobsen records a series of examinations of prescription bottles which have demonstrated the presence of alkali in a soluble condition sufficient to give decided reaction when water after contact with the glass was titrated with $\frac{\sqrt{1}}{\sqrt{0}}$ HCl using phenolphthalein as indicator. As an example, a number of vials of different capacities were each rinsed, drained, and set aside 24 hours; then portions of 10 Cc. of water were shaken in each vial and titrated with phenolphthalein as indicator. In almost every instance alkalinity of the water was demonstrated. On subjecting the same vials, containing 10 Cc. of pure water, to sterilization during one hour in a current of steam, the water in every case showed strong alkalinity, the quantity of $\frac{\sqrt{1}}{\sqrt{0}}$ HCl required for saturation varying according to the size of the vial as well as the quality of the glass. Direct experiments also demonstrated that morphine was precipitated from neutral solutions of the hydrochloride when sterilized and kept during 24 hours in some of these glasses.—Apoth. Ztg., xxv (1910), No. 30, 262.

Beaker Flasks—A New, Graduated Form.—Prof. A. Junghahn has devised a new distilling flask combining the advantages of the ordinary form of the beaker with that of the flask and measuring glass. The new flask is shown in two shapes by Figs. 47 and 48, the one with a flat bottom, the other rounded. The graduation enables the addition of definite volumes of different liquids in operations requiring their admixture, or to distil off
a definite volume of the contents without the necessity of using the usual accessories, while, on the other hand, they adapt themselves to all the individual purposes for which the beaker, flask or graduated measure are commonly employed. The flasks are, however, also employed without graduation.—Pharm. Ztg., lv (1910), No. 13, 127.

Three-necked Flask—A Form Suitable for Organic Work.—Emil Maas describes a new form of flask, which is particularly adapted for organic experimental work. As shown by Fig. 49, it is provided with three tubulures, the central one being large enough to permit the introduction of a mechanical stirrer, one of the side tubulures being intended for a dropping funnel, the other for a thermometer. The flask adapts itself for reduction operations in organic work, the central tubulure here serving the purpose of being a cooler, while the third tubulure permits the introduction of metallic sodium (Fig. 50).—Pharm. Ztg., liv (1909), No. 91, 900.

The Ampul and Its Uses in the Preservation of Sterile Solutions is the title of an illustrated paper by Caswell A. Mayo, showing and explaining the ampuls of various shapes and sizes, the methods of filling, and the apparatus necessary for the purpose. The voluminous paper appears in the "Proceedings," 1909, 1106–1122.

Ampul Filler.—Efficient Form.—Dr. Wulff has constructed a new apparatus for filling ampuls which is shown by Fig. 51. It consists of a graduated measuring tube, having two scales, the one intended for measuring the quantity to be introduced into the ampul, the other to accurately adjust the quantity. It is surmounted by a reservoir from which the fluid is supplied by a turn of the glass cork, the inflow being regulated by a small
tongue-shaped tube, securing equability of flow and preventing frothing of the liquid. A small hole in the upper part of the tube, loosely stoppered with cotton, establishes communication with the outer air. The filling is done by means of a hypodermic needle attached to the lower orifice of the graduated tube by means of a rubber tube closed with a clip in the usual manner. Obviously, the apparatus may be utilized for a variety of purposes requiring accurate measurements of fluids. Pharm. Ztg., lv (1910), No. 21, 212.

Capped Bottle.—Improved Construction.—Wetzel has devised the new form of capped bottle shown by Fig. 52 which is provided with a cup-shaped ground-glass stopper for the reception of a suitable material to absorb the moisture in the air enclosed within the glass cap carefully ground to fit the shoulder of the bottle. The device thus efficiently excludes moisture from the material preserved in the body of the bottle. Pharm. Ztg., lv (1909), No. 99, 975.

Eyedrop Bottle and Dropper—Efficient Form.—Dr. Emanuel has devised the eyedrop bottle with dropper shown by Fig. 53, in which the eye-drops may be sterilized and maintained sterile until completely used. It consists of the bottle \( a \), the dropper \( b \), protected by the ground-glass cap
c, and the truncated funnel-tube d, closed with a rubber membrane. The bottle, the glass cap, and the rubber membrane are first boiled separately; the liquid is then poured into the bottle through the funnel-tube, subjected to brief boiling over the flame, and the funnel is then closed with the rubber membrane; while the dropper is protected by fitting on the glass cap. Simple pressure on the rubber membrane regulates the flow of drops, and the contents of the bottle are perfectly protected in a sterile condition until the last drop is used.—Pharm. Ztg., lv (1910), No. 21, 212.

**Bottle Filler—A Home-Made Device.**—C. A. Charles has used with convenience and satisfaction the home-made bottle filler shown by Fig. 54, which can be constructed at a trifling expense with such apparatus and material as is usually on hand. The reservoir for the liquid to be filled consists of a glass percolator (A), provided with a cover (G) bearing a funnel (B) to convey fresh supply of liquid into the percolator. A piece of telegraph wire (C) passes through the centre of the cover and ends in a rubber stopper (D), closing the orifice in the neck of the percolator, over the outer extremity of which a short section of rubber tube (E) is stretched, into the extremity of which, in turn, a perforated cork bearing a short section of glass tubing is inserted, as shown at (H) in the
drawing—the calibre of this glass tubing being such as to conveniently fit into the neck of small bottles, as shown at (F). The application of the device is obvious, the flow of liquid from the percolator resulting on raising the stopper (D) by means of the wire (C), and effectually ceasing on again pressing the stopper into place.—Drugg. Circ., Nov., 1909, 587.

*Bottle Draining and Drying Closet—A Convenient Receptacle for Prescription Ware.*—Herman Herwald has patented (in Germany) the convenient draining and drying closet for prescription bottles shown by Fig. 55, which requires little explanation. These closets are constructed of different sizes, according to requirement, the one here shown having 18 compartments or drawers accommodating 1600 bottles of all sizes, from 5.0 to 1000.0 capacity. The drawers have the same superficial size, but differ in height; they are lined with zinc, the bottom being slightly inclined toward the rear so that the rinsing water may escape through an appropriate orifice and collect in a common receptacle at the bottom of the closet, from which it is automatically carried into a common drain. The rear wall of the closet, similar to the drawers themselves, is also zinc lined.—Apoth. Ztg., xxiv (1909), No. 91, 859.

*Collapsible Tubes—Label Attachment.*—George Wenderoth has introduced collapsible tubes with a tag attachment for labeling contents, which, as shown by Fig. 56, recommends itself as a practical device in dispensing prescriptions for ointments, pastes, etc.—Pharm. Ztg., liv (1909), No. 91, 900.
Drug Jars—Improved Form.—W. Haldenwanger has patented an improved form of drug jar which, apart from its pleasing shape, possesses certain practical advantages over the shop jars ordinarily in use. As shown by Fig. 57, the bottom of the jar is rounded on the inner surface, so as to avoid the sharp angles of the usual form, thus facilitating the complete removal of the contents and the subsequent cleaning, while the mouth of the jar flares outwardly, permitting the introduction of the hand or finger for the same purpose.—Pharm. Ztg., liv (1909), No. 82, 811.

Porcelain Drug-Jars — Important Improvement.—Doering calls attention to the improved white porcelain drug jars and containers which have recently been introduced by the Berlin firm of Bach & Riedel. These jars, while white on the outside and in no way distinguished in appearance from the ordinary shelf ware, are glazed on the inner surface impenetrably black, thus excluding light completely from the substances contained in them.—Pharm. Ztg., liv (1909), No. 85, 839.

White Enameled Ware—Utility in Laboratory Operations.—E. Fullerton Cook calls attention to a line of white enameled ware, sold in the house goods departments of many stores, which may be applied with great advantage to many drug-store laboratory operations. He has used them for water-baths for several years. The plates admirably adapt themselves to covers for funnels and percolators. The bowls, of many sizes, are inexpensive and strong and clean, and may be used in innumerable ways and for almost every purpose for which a porcelain dish is required.—Amer. Journ. Pharm., Sept., 1909, 417.

Aluminum Utensils—Precaution against Contact with Mercurials.—"J. Sch." observes that while it is generally well understood that alkalies, soap, acids, etc., act unfavorably on aluminum, it is not so well known that certain dry salts, particularly those of mercury, are injurious to aluminum utensils, converting the metal into oxide. Mere traces of corrosive sublimate, for example, in contact with an aluminum surface produce spots consisting of alumina, the mercury being reduced and further injuring the aluminum by forming an amalgam. While aluminum is of itself combustible in air, to form aluminum oxide a superficial thin layer of oxide is almost instantaneously formed on the surface, and this protects it from further oxidation.—Pharm. Ztg., lv (1910), No. 34, 346.

Zinc Containers—Corrosion by Alum.—Dr. O. Langkopf having opportunity to subject an incrustation which had formed in a zinc canister used for storing alum, found that this incrustation was caused by the decomposition of the alum incited by high temperature and involving the container itself. The explanation is as follows: Primarily the zinc was oxidized by
the high (climatic) temperature prevailing and by the moisture supplied by the vaporization of the water of crystallization of the alum. In turn the zinc oxide precipitated alumina from the aluminum sulphate and was converted into zinc sulphate, water being again liberated, thus facilitating the further oxidation of the zinc.—Pharm. Zentralh., 57 (1910), No. 17, 333.

**Round Labels—An Extemporized Receptacle.**—L. W. Marshall gives the following directions for constructing the convenient receptacles for round labels shown by Fig. 58: "Procure a block of wood and have a carpenter saw holes the size of the paper used. Save the round blocks. Take pieces of heavy cardboard (or pieces of mailing tubes and cut slits up their sides about an inch wide) and insert them in the openings and place the round blocks back. The latter will hold the tubes in place."—Drugg. Circ., Aug., 1909, 399.

**Label Requirements in State Pure Food and Drug Laws** is the subject of a paper by E. G. Eberle which appears in the "Proceedings" of 1909 (p. 693-695), in which attention is directed to some of the difficulties encountered in compliance with the requirements, some of which are of questionable necessity or utility.

**A Convenient Paste-Pot** is according to E. Fullerton Cook's suggestion constructed as follows: A quart, pure aluminum kettle, having an aluminum lid slipping on but fitting lightly, both drawn from a piece of sheet aluminum and very strong, is purchased. The handle is removed and a round hole, one and one-half inches in diameter, punched in the center of the lid, after which the top is depressed towards the center by using considerable pressure. Then selecting a good brush of suitable size—the best of these being bound in a metal which is not liable to rust—the metal winding is first shellacked, then wrapped closely with twine from the bristle to the wood, and this winding in turn is heavily shellacked with two or more coats. A disk of rubber, about one-fourth inch thick and 2 inches diameter is now cut from a rubber stopper, a hole punched in the center,
DISPENSING OF MEDICAL PRESCRIPTIONS.

and the brush handle is fitted into this. When the brush is standing in the pot, the rubber disk effectually excludes air and prevents the paste from drying, and when the brush is to be used the excess of paste may be wiped off as it is withdrawn. Amer. Journ. Pham., Sept., 1909, 415-416.

Pill Finisher—A Self-Adjusting Device.—Walter Ruch describes a self-adjusting pill-rounder and finisher which he has found quite convenient and satisfactory. It consists of a flat circular box open at the bottom, a thin disk fitting the interior of the box, which is movable vertically by means of a piston extending through the top of the box, the top of the piston having a knob attached for placing the finger. When using simply place the pills beneath the box. This raises the disk according to the size of the pills and by means of the finger on the knob of the piston any decided pressure may be exerted upon the pills beneath, which may now be rolled and finished perfectly.—Proc. N. J. Pharm. Assoc., 1909, 45.

GENERAL SUBJECTS.

The Profession of the Practicing Pharmacist is the title of an interesting paper by C. S. N. Hallberg which appears in the “Proceedings” of 1909 (pp. 686-693). The author discusses his subject chiefly from the historical and ethical standpoint, and concludes with the relation of the medical code of ethics to pharmacists, leading to the “Declaration on the Prescription” adopted tentatively by a number of branches of the A. Ph. A., and covering the following propositions: 1. The attitude to the prescription. 2. The prescribing by druggists. 3. The dispensing by doctors.

Should the Dispensing of Medical Prescriptions be Exclusively Confined to Pharmacists? is the title of a paper read by the president of the British Pharmaceutical Conference at the Newcastle-on-Tyne meeting in 1909, which was animatedly discussed by both pharmacists and physicians present, the consensus of the opinions expressed being distinctly in support of the decided opinion held by President Tocher that the dispensing of medical prescriptions should be confined to pharmacists. It was proposed that a joint standing committee of members of the British Medical Association and of the British Pharmaceutical Conference should be created, whose preliminary duties would include: (1) dispensing problems; (2) prescribing problems; and (3) drug problems. Beginning with the collection of data and information, the annual reports as time goes on would give an idea as to the steps necessary to bring about a more satisfactory relation in this respect between physicians, pharmacists and the public, for it has been a practice from time immemorial for doctors to supply their own physic; and if any practical measure can be devised whereby they could be relieved of this encumbrance to their work, medical men will surely hail the measure with joy, and the change will redound to the benefit of all parties concerned—the doctor, the pharmacist, and the pub-
lic. This admirable paper and the discussion following are well worth more than casual perusal by pharmacists in our own country, who, on different grounds, are confronted with a similar problem.—Trans. Brit. Pharm. Conf. (Yearbook of Pharm.), 1909, 279–292.

Revision of the U. S. P.—Suggested Standards and Changes.—Charles H. LaWall publishes notes collected during a period of several years, embodying observations made from a practical application of the various tests and requirements of the U. S. P. in examining a large number of substances. While some of them are not entirely new, a number of them, as far as known to the author, have not appeared in pharmaceutical literature, and are submitted as being in the lines of constructive criticism. This interesting paper may be consulted in Amer. Jour. Pharm., Jan., 1910, 21–26.

The National Formulary: a Criticism! is the title of a voluminous paper in which H. G. Posey criticizes a very large number of the formulas at present in the N. F. This paper is printed in the “Proceedings,” 1909, 980–998.

Modifications of U. S. P. and N. F. Formulas are suggested by John A. Dunn in a paper which is published in the “Proceedings,” 1909, 942–959. Similarly,

Some Suggestions for Improvements in the National Formulary are made by a committee of the Philadelphia Branch of the A. Ph. A., which appear in the “Proceedings,” 1909, 959–963, and by Mr. Bruder, chairman of a Special Committee of the Chicago Branch, on pp. 963–967; while

Laboratory Notes on Some N. F. and Other Preparations are contributed by J. D. Aug. Harz, on pp. 967–971; and

Suggestions for the Modification of Certain N. F. Preparations are made by A. Alton Wheeler, on pp. 971–973 of the same “Proceedings.”

Broadening the Usefulness of the National Formulary is the title of a paper by Frederick E. Niece, which appears in the “Proceedings,” 1909, 976–979.

Manufacturing Notes on Some Official Preparations are contributed by F. W. Nitardy in which he suggests improved formulas for syrup of senega, comp. solution of sodium phosphate, and several elixirs. The paper appears in the “Proceedings,” 1909, 1055–1058.

Galenical Preparations.—Refractometric Examination.—W. B. Cowie and J. O. Broadbent record the results of some preliminary experiments undertaken with the object of ascertaining the possible utility of a refractometric method of examination of galenical preparations for determining the character of the extraction and the absence of extraneous matter. They have applied a method, which is explained in some detail, to fluid-
exacts of cascara sagrada of their own make and from commercial sources, and find the refractive indices to agree well with the specific gravity and amount of extraction. Trans. Brit. Pharm. Conf. (Year-book of Pharmacy) 1909, 323-324.

Alcoholic Galenicals—Reduction of Alcohol and Substitution of other Solvents.—D. B. Dott observes that while the B. P. of 1885 directs proof spirit as the weakest menstruum for preparing tinctures, that of 1898 directs in some cases a menstruum as low as 45 per cent. alcohol, and he raises the question whether this reduction in alcoholic strength cannot be still further extended in the preparation of tinctures and similar galenicals. He mentions quite a number in which he thinks this can be done with advantage and without reducing the medicinal value of the preparation. Some of them might be reduced from 90 to 70 per cent. (orange, lavender compound, lemon, podophyllum); others from 70 to 60 per cent. (cascara, cinchona, cinnamon, conium, pyrethrum); or from 60 to 45 per cent. (calumba, chiretta, saffron, digitalis, ergot, rhatany, hops, quillaya, squills and senega; while tinctures of aloes, cochineal, hyoscyamus, opium, quassia and stramonium might be reduced from 45 to 30 per cent. The author also mentions the advantages of using in some cases glycerin or acetic acid, wholly or in part, as menstrua for galenicals in which alcohol, more or less diluted with water, is now used.—Trans. Brit. Pharm. Conf. (Year-book of Pharmacy), 1909, 331-333.

Spirituos Galenicals.—Estimation of Extractive and Glycerin.—W. A. H. Naylor and F. J. Chappell have experimented to determine a method suit-
Tube $B$ is bent, and cut off level with the inside of the stopper $C$. The flask is immersed up to the neck in a bath of a suitable liquid—glycerin itself answers well. In the bath is a coil of compo tubing connected to $A$ by pressure tubing with a screw clip. This connection should be made so as to leave as little of the tubing outside the bath as possible. Tube $B$ is connected by glass tubing, joined by short lengths of pressure tubing, to two Woulff's bottles containing water to a depth of about $\frac{1}{2} - 1$ inch above the ends of the delivery tubes. These in turn are connected with a water pump and a manometer. To conduct an estimation introduce 5 Cc. or other suitable quantity of the galenical into the flask, previously weighed. Place the flask in the bath and connect it to the Woulff's bottle and the coil, the screw clip being closed. Exhaust the apparatus till the pressure is about 18—20 Cm., and then by carefully opening the clip allow a slow current of washed air to pass through the flask—meanwhile raising the temperature of the bath to 150—140° C. When all the spirit and water have passed over known by the tube $B$ becoming cool—connect the compo coil with a steam generator, and admit steam very gently at first, to avoid splashing, and then gradually increase the current to a fairly rapid one, which should be continued for three hours, the pressure being maintained at 18—20 Cm. At the end of this period carefully admit washed air till the pressure reaches the normal again. Disconnect the apparatus and wash the stopper and tube $B$ with distilled water, adding the washings to the distillate. Any extraction remaining in the lower end of tube $A$ should be washed into the flask by a suitable solvent, and the flask and its contents dried in an air oven at 110° C. and weighed. This gives the extractive. Concentrate the washings to about 5—10 Cc., filter, wash the basin and filter paper, and make the filtrate up to a definite volume. Determine the glycerin in this filtrate, or in an aliquot part of it, by Hehner's bichromate method as modified by Richardson and Jaffé (Journ. Soc. Chem. Ind. 1898, 330), omitting the treatment with lead subacetate, etc. The results by this method, as applied to a large number of preparations in which the glycerin and extractive contents were known, are given in a table, and prove the accuracy and reliability of the method if carried out with reasonable care. Trans. Brit. Pharm. Conf. (Year-book of Pharmacy) 1909, 260—265.

B. Preparations.

AQUÆ.

Ammonia Water—Presence and Detection of Pyridine.—Herman Kunz-Krause, discussing the G. P. test for the absence of certain cyclic amino compounds which, like pyrrol and the bases of the aniline and pyridine series, produce a more or less red-colored instead of a colorless nitrate when ammonia water is evaporated to dryness with nitric acid in excess,
observes that pyridin is practically the only base that requires consideration, but that its presence in ammonia water is more frequent than is generally supposed. A less circumstantial test than that of the G. P. is therefore a desideratum, and such he finds in the following, which is based on the pronounced and characteristic disagreeable odor of the pyridine and depends on the fact that ammonia is a stronger base than pyridine, and remains in a free state along with the excess of ammonia when the ammonia water is treated with insufficient acid to complete neutrality. The proposed test is carried out by placing 5 Cc. of the ammonia water into a capacious test-tube, the mouth of which can be conveniently closed with the thumb, and adding, in small portions at a time, but as rapidly as possible, 2 Gm. of finely-powdered tartaric or citric acid, incorporating the powder if it forms lumpy aggregations by means of a glass rod. Before and at the end of last addition of the acid, the mixture is vigorously shaken and tested by the smell. On the disappearance of the ammonia odor by the heat of reaction, that of pyridine, owing to its high vapor tension, is retained and manifests itself unmistakably by its penetrant and nauseous quality.—Apoth. Ztg., xxv (1910), No. 11, 87.

**Bitter Almond Water—Decomposition.**—Dr. F. M. Litterscheid, having noticed that perfectly clear solutions of the hydrochlorides of morphine, codeine and dionine, in bitter almond water of apparent official quality, soon became turbid and gradually formed a deposit, traced this unusual reaction to the presence of ammonia. Further investigation leads him to regard the amorphous precipitates to be impure condensation products of ammonia and benzaldehyde, the ammonia resulting from the decomposition of the bitter almond water, the hydrogen cyanide in aqueous solution being under certain conditions readily converted into ammonium formate. This impurity may be removed by treatment of the bitter almond water with a little blood-charcoal and filtration after standing about one hour.—Apoth. Ztg., xxv (1910), No. 13, 106.

**Cherry-Laurel Water, Ph. H. IV—Reliability of the Formula.**—Supplementing his previous studies concerning the conditions demanded to produce a reliable cherry-laurel water (see Proceedings 1909, 65), Dr. K. Siegfried has made a comprehensive study of the subject, with particular reference to the demands of the Swiss Pharmacopoeia, IV, which has been the subject of numerous criticisms (by Fleissig, Berger, Weitbrecht, Guerin, Gouet and others). Referring for the details of this study to the original, the author’s results are briefly summarized as follows:

1. The formula of Ph. H. IV, is correct and reliable.
2. The demands of this standard can be complied with.
3. It is desirable, however,—
   a. That leaves gathered after the flowering period may also be used.
   b. That the specific gravity 0.9940 to 0.9960 be adopted.
c. That, in place of "neutral reaction," faint acid to neutral reaction be permitted.

d. That, as proposed by Dr. Weitbrecht, cherry-laurel water is to be carefully preserved, protected from light, in completely filled bottles, of at most 250 Cc. capacity, and well stoppered.

e. That the determination of quality (and identity) be made with the aid of sodium bisulphite.—Schw. Wschr. f. Ch. u. Pharm., xlvii (1909), No. 36, 542–549.

_Distilled Cinnamon Water—Manipulation._—A writer in the "Südd. Apoth.-Zeitung" (1909, No. 60) observes that the German pharmacopœial description of the characteristics of cinnamon water, "turbid when first distilled, afterwards becoming clear," should be supplemented by the further characteristic of having an agreeable sweet, followed by a sharp burning taste. But to obtain such a cinnamon water, the coarsely powdered cinnamon should not be macerated for 12 hours with the necessary quantity of alcohol by itself (as is the case when the so-called 1:100 cinnamon water is made? Rep.), but it is absolutely necessary to macerate with a mixture of alcohol and water, the latter in large preponderance (1:8). This effects the opening out of the cellular tissues so that the volatile constituents of the bark pass completely into the distillate, which possesses all the characteristic requirements above indicated and an aroma with which the water obtained by dilution of the concentrated (so-called 1:100) cinnamon water, or that obtained from the volatile oil itself, will not bear comparison.—Pharm. Ztg., liv (1909), No. 62, 601.

CAPSULE.

_Soft Capsules—Importance of Fresh Preparation._—In the course of some observations on the facility and advantages of dispensing freshly-filled soft capsules, Louis Emanuel, Jr., mentions some experiments made to determine the effect of age on the capsules. While a fresh, home-filled capsule was completely dissolved in an acidulated pepsin solution within eight minutes, another of the same lot, taken from the stock a month later, required fourteen minutes; another, three months old, twenty minutes, and when a year old one of the same capsules required three hours and ten minutes for complete solution.—Amer. Drugg, April 11, 1910, 193.

ELIXIRIA.

_The National Formulary Elixirs_ are the subject of a paper contributed by William Mittelbach, which appears in the "Proceedings," 1909, 973–974.

_The Perpetuation of Elixirs in the National Formulary_ is discussed in a paper by M. I. Wilbert, who regards their perpetuation as evidence that we have not kept in touch with the advances made in pharmacology and
drug therapy. This paper appears in the “Proceedings,” 1909, 1044–1047.

**New Basic Elixirs—Formulas Recommended for Inclusion in the N. F.**

George M. Beringer contributes a number of formulas for basic elixirs to be included in the National Formulary for the purpose of replacing some of the basic elixirs now directed in certain preparations, whereby they may become more satisfactory both in regard to flavor and in alcoholic content, a reduction of the latter being particularly desired in the formulas for some of the sedative elixirs, such as ammonium valerate, chloral hydrate and the bromides. Referring to the original paper for the formulas for these new basic elixirs, these are here mentioned by their titles, as follows:

- Elixir Amygdalae Compositum—Compound Elixir of Almond.
- Elixir Cardamomi Compositum—Compound Elixir of Cardamom.
- Elixir Curassao—Elixir of Curacao.
- Elixir Vanillinæ Compositum—Compound Elixir of Vanillin.

Formulas are also given for “Compound Spirit of Cardamom” and for “Compound Spirit of Vanillin,” which are needed in the formulas for these basic elixirs.—Proc. Penna. Pharm. Assoc., 1909, 251–255.

**Vehicula—A New Class of N. F. Preparations.**—In a paper read before the Pittsburg Branch of the A. Ph. A., Louis Emanuel says there is need for a class of fluid preparations to be used as vehicles, or solvents, differing in character from any preparations at present available for the purpose indicated. That this is true is evidenced by the great popularity of a number of proprietary preparations which have made their appearance and been eagerly taken up by the medical fraternity during the past decade. Mr. Emanuel therefore urges the “Branch” to use its best efforts toward bringing about the adoption by the National Formulary Committee for inclusion in that volume of formulas the following new class of preparations which may be used as solvents, diluents or vehicles:

**Vehiculum Rubrum.** (Red Vehicle.)

The fruit of Ananassa sativa is pared and sliced, ground in a gem chopper, and the juice expressed through muslin. The juice is then mixed with the alcohol, glycerin and purified talc, 7.00 Gm. Allow the mixture to stand for 24 hours and filter through paper, or filter immediately.

Vehicle peppermint, cinnamon, etc., may be prepared by simply adding 20 parts of glycerin to 80 parts of the respective medicated waters.—Midl. Drugg. and Pharm. Rev., Febr., 1910, 32-33.

Elixir of Gentian, N. F.—Modification of Formula.—George M. Berger, believing the process of detannating the gentian both unnecessary and harmful, suggests the addition of an alkali citrate which prevents the tendency of iron salts to blacken the elixir when used in connection therewith, and proposes the following as a substitute for the present N. F. formula:

- Fluidextract of gentian: 35 Cc.
- Comp. spirit of cardamom: 15 Cc.
- Sodium citrate: 30 Gm.
- Glycerin: 50 Cc.
- Syrup: 250 Cc.
- Alcohol: 200 Cc.
- Purified talc: 20 Gm.
- Water, a sufficient quantity to make: 1000 Cc.

Dissolve the sodium citrate in 350 Cc. of water. Add to this solution the fluidextract of gentian and then the glycerin. Mix the comp. spirit of cardamom and the alcohol, and gradually add this to the other mixture, shaking well after each addition. Then add sufficient water to make the product measure 1000 Cc. Add the purified talc and filter.—Proc. Penna. Pharm. Assoc., 1909, 538-539.

Elixir Gentiana Glycerinatum may be improved, according to J. Diner, by using compound spirit of orange as a flavoring, according to a formula which he proposes in the "Proceedings," 1909, 1161.

Elix. Iron, Quinine and Strychnine Phosphate, U. S. P., viii—Modification of Formula.—Adolph F. Marquier proposes the following modification of the official formula for elixir of iron, quinine and strychnine phosphate:

- Ferric phosphate (soluble): 32.0 Gm.
- Quinine phosphate: 8.5 Gm.
- Strychnine phosphate: 0.24 Gm.
- Oil Sweet Orange: 2.0 Cc.
- Alcohol: 250.0 Cc.
- Glycerin: 300.0 Cc.
- Distilled water, a sufficient quantity to make: 1000 Cc.
Dissolve the ferric phosphate in 300 Cc. of distilled water by cold maceration; dissolve the quinine and strychnine phosphate in 150 Cc. of hot water; dissolve the oil of sweet orange in the alcohol; now add the alkaloidal solution to the glycerin, then the iron solution, alcoholic solution and enough distilled water to make 1000 Cc. Lastly, allow to stand 24 hours and filter. Preserve in dark bottles.—Proc. N. J. Pharm. Assoc., 1909, 47.

_Elixir of Phosphate of Iron, Quinine and Strychnine.—Improvement of U. S. P. Formula and Manipulation._—S. A. Sharp says that the working process of the official "Elixir of Triple Phosphate" requires much care and accuracy in manipulation and that the formula is improved by the addition of one grain of potassium citrate to the fluidounce, whereby all of the ingredients are rendered soluble and compatible. By carefully following the formula and directions here given a permanent preparation is speedily obtained;

Dissolve the phosphorus iron scales in 150 Cc. dist. water with heat; and the phosphorus quinine in 150 Cc. dil. alcohol containing the phosphoric acid. To the solution of phosphorus iron add the citrate of potass. and the phosphorus strychnine. Heat the Elixir of Orange to about 100° F. in a closed vessel and add the solution of phosphorus quinine and lastly the solution containing the iron, strychnine and potass. citrate previously warmed to about 100° Fahr. Filter, if necessary, and protect from light, in dark amber bottles. Pacific Pharm., Jan., 1910, 290–291.

_Compound Elixir of Pepsin—Improved Formula and Title._—Having become convinced by personal observation as well as from the literature that compound elixirs of the digestive ferments have an extensive use in medical practice, George M. Beringer maintains that it is not within the province of the National Formulary to recommend, nor to advise, nor to question, the therapeutic action of remedies dispensed on physicians' prescriptions, and that as long as it makes no claim for the product it is only filling its mission and keeping well within its intended scope by simply supplying approved formulas. The question of the therapeutic incompatibility is one that the pharmacist cannot consider and, if introduced, would certainly queer many prescriptions. While, therefore, not in the least defending either the therapeutic action or the chemistry of these compound
preparations of the digestive ferments, the author insists that a necessity exists for the retention in the N. F. of one, the "Compound Digestive Elixir," for which he proposes an improved formula and the changes of title to "Compound Elixir of Pepsin." It is proposed to have the elixir approximately represent one-tenth of the powder, or 100 Gm. of compound powder of pepsin in 1 liter of elixir. The flavoring is orange, and by the use of powdered cudbear a greater uniformity in product of different stores will be secured.

The following formula is submitted:

_Elixir Pepsini Compositum._ (Compound Elixir of Pepsin.)

Mix the acids with the glycerin and 500 Cc. of water, add the pepsin, pancreatin and diastase, and macerate with occasional agitation until solution is effected. Then add gradually the alcohol, in which the oil of orange has been dissolved, agitating after each addition. Now add the cudbear and sufficient water to make the preparation measure 1000 Cc. Macerate for six hours with occasional shaking and then filter.—Amer. Jour. Pharm., July, 1909, 331-336.

_Elixir of Lactated Pepsin_ is the title of a paper presented to the Association by W. A. Pearson, which appears in the "Proceedings," 1909, 905-907.

_Essence of Pepsin, N. F._—_Satisfactory Stability._—Mrs. D. V. Whitney, referring to the statement sometimes made that essence of pepsin, N. F., rapidly deteriorates, becomes unsightly and inert, brings experimental evidence that this preparation compares favorably with the most popular proprietary article. A sample prepared in conformity with the N. F. formulas, originally having a pepsin content corresponding in strength to 1 : 2600, after four months was perfectly clear and proved to have a pepsin content corresponding to a 1 : 2365 strength by the U. S. P. test, and after two years still showed a pepsin value of 1 : 1183. During the same time the proprietary article under identical conditions had depreciated to 1 : 916 pepsin value. The milk-curdling effect of the two specimens, similarly, showed a celerity in forming a coagulum which was decidedly in favor of the N. F. preparation.—Proc. Mo. Pharm. Assoc., 1909, 103.
**Plasters in the Pharmacopoeia—Necessity for Revising their Formulas.**—Fred. B. Kilmer has contributed an exhaustive paper in which he criticises the shortcomings of the U. S. P. in the changes effected at the last revision in the formulas for plasters. These shortcomings are mainly the result of the change in the composition of the base of the plasters, by which the attempt was made to convert the adhesive plaster into a "rubber adhesive plaster." He arrives at the conclusion that the mass or base introduced into the U. S. P. under the head of "Adhesive Plaster" should be abandoned, and that a mass or base more nearly resembling that of the lead plaster of 1890 be restored; and, furthermore, that if such a course be possible, the alternative use of any India rubber mass such as now employed by manufacturers be allowed. Also, that assay processes be prescribed for all plasters containing alkaloids or definite medicinal components.—Proc. N.J. Pharm. Assoc., 1909, 105-113.

**Medicinal Plasters—Assay.**—Frederick B. Kilmer says that prior to the issue of the U. S. P., VIII, no authoritative process of assay of any medicinal plaster appeared in that work. In this revised edition a process is given for the assay of mydriatic alkaloids in belladonna plaster, but he finds it a very difficult matter to make this assay, chiefly because of the rubber base, and considers it probable that similar difficulty will arise from the same cause if an assay is attempted of the other rubber base plasters. He has worked out assay processes for belladonna plaster, salicylic acid plaster, mercurial plaster, ammoniac and mercury plaster, and iron plaster, which he submits for possible use in the revision of the U. S. P.—Amer. Journ. Pharm., March, 1910, 112-118.

**Rubber Adhesive Plasters—Formulas Adopted by the Medical Administration of the German Army**—After a review of the conditions that are required to produce rubber adhesive plasters of uniform and satisfactory efficiency, Budde communicates the following formulas which have been officially adopted by the medical administration of the German army after comprehensive studies and experiment:

I. **Rubber Adhesive Plaster.**

134.0 anhydrous woolfat are melted with 16.0 copaiba and the mixture is heated for a short time to 100° C. The partially cooled mixture is then dissolved in 60.0 petroleum benzine, and when cool a solution of 50.0 caoutchouc (Para) in 300.0 petroleum benzine is added. The whole is then intimately mixed by agitation with a finely-divided triturate of 50.0 powdered orris rhizome and a sufficient quantity of petroleum benzine, and is ready for use. It is spread upon unstarched "shirting" so as to form a total thickness of 0.9 mm.
II. Rubber Plaster with 20 Per Cent. Zinc Oxide.

134.0 anhydrous woolfat and 16.0 copaiba are melted together, heated for a short time to 100° C., allowed to cool, and triturated with 57.0 zinc oxide and 27.5 powdered orris rhizome so as to form a homogeneous ointment. The mixture is then gently heated, diluted with 60.0 petroleum benzin, and intimately mixed by shaking with a solution of 50.0 caoutchouc (Para) in 300.0 petroleum benzin.

This mixture may then be spread at once on unstarched "shirting" (64 threads to the Sq. Cm.) to the thickness of 0.9 Mm.—Pharm. Ztg., liv (1909), No. 52, 507.

Rubber Plaster, Fr. P.—Unsatisfactory Formula.—The formula of the recently published French Pharmacopoeia is unfavorably commented on by L. Cavailles and C. Pepin. The official directions require the rubber to be dissolved in benzin; and dammar, separately, in a mixture of oil of turpentine and alcohol. Beeswax and woolfat are to be melted on the water-bath and mixed with liquid paraffin. The rubber solution is then to be mixed with this, and the mixture is allowed to cool. Then the dammar solution is to be added carefully, and the whole is to be heated on the water-bath at a temperature not exceeding 50° C. until the volatile ingredients have been evaporated. The residue is to run into a pot. This process is condemned as unnecessarily complicated and wasteful. The alcohol and oil of turpentine are needless. The solid consistence is not convenient. The dammar is simply melted on the water-bath with the wax, wool fat, and liquid paraffin. The warm liquid is strained through muslin and the solution of rubber in benzin is added. This gives a semi-liquid mass, which keeps well in a closed vessel, and is readily incorporated with other ingredients in the cold. Its consistence is well suited for spreading. After drying in the air for two or three hours it has a good adhesive surface.—Pharm. Jour. and Pharmacist, May 21, 1910, 645; from Journ. de Pharm. et Chim., 1910, i, 393.

Lead Plaster—New Formula.—Fr. Bergh recommends the following new formula for lead plaster:

Lithargyrum ......................................................... 50.0
Acid, olein depur .................................................. 90.0
Stearinum .............................................................. 10.0
Glycerinum ............................................................ 3.0
Spiritus concentratus ............................................... 10.0

EMULSA.

The Emulsions of the National Formulary are the subject of some notes by A. B. Stevens, which appear in the "Proceedings," 1909, 974–975.
Commercial Emulsions—Method of Determining the Oil Content.—In the course of an examination of a large number of commercial emulsions, E. W. Pollard perfected a "dry" method of assaying the amount of oil in them, which possesses a number of advantages over the method commonly in use—such as milk analysis—and is described as follows: A small "mound" (about 5 Gm.) of dried sodium sulphate is made in a watch-glass, and a "crater" capable of holding 2 Gm. is formed on top. The weight is taken, the "crater" filled with emulsion, the weight again taken, and the contents of the watch-glass tipped into a mortar; the glass will be left perfectly clean. After absorption of the emulsion the sulphate is triturated and the small nodules formed broken up by the addition of 10 Gm. of coarse sand. The powder thus formed is transferred to the extractor and the mortar rinsed twice with carbon tetrachloride. Extraction is allowed to go on vigorously for two hours. In this way an anhydrous solution is obtained which, after the distillation of the solvent, requires only an hour to dry in the water-oven; nor should longer be allowed. During the drying the flasks are preferably laid on their sides to allow the escape of the heavy carbon tetrachloride vapor. The iodine figure may be obtained by a second extraction, using the carbon tetrachloride solution without distillation. The process is also suitable for malt and oil, providing only a small quantity be taken. Concerning the

Preparation of Emulsions, the author gives decidedly the preference to the method as exemplified in the Emulsio Olei Morrhuæ, B. P. C., which consists in mixing the powdered acacia with the whole of the oil, then adding the water secundum artem. The "alternate" method of the B. P. C., as exemplified by Emulsio Olei Morrhuæ Comp., is successful only when the proportion of oil is sufficiently high to form a jelly. A third method, by "churning," is adapted only to large quantities, and then only when the menstruum is quite thin; with thick emulsions the manipulation is not easy nor, in the author's judgment, satisfactory. A good pharmaceutical emulsion, in addition to keeping qualities, is one—(1) which is no more viscous than glycerin; (2) in which the globules do not exceed 15 μ; (3) which on dilution throws down no sediment.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 266–278.

Emulsion of Iodoform—Preparation Suitable for Surgical Dressing.—P. I. Minton recommends the following formula for an emulsion of iodoform which remains indefinitely perfect and is free from the undesirable adhesiveness imparted by the ordinary emulsifying agents:

Iodoform, a sufficient quantity.
Hydrous lanolin ................................................. 2 ounces.
Cottonseed oil, enough to make ................................ 1 pint.

Triturate the iodoform with enough cottonseed oil to form a smooth
paste. Add the lanolin, rub the mass until smooth, and then add the remainder of the oil with constant trituration.—Bull. Pharm., Nov., 1909, 472.

Extracta.

Plant Extracts.—Preparation in an Unaltered Active Condition.—A. Goris describes a method devised by Perrot and himself for destroying the natural ferments of plants and extracting their active principles in the actual state in which they exist in the plant tissues. Alkaloids and glucosides are often found in fresh plants in complex combinations with tannins or other bodies, in a condition which renders them soluble in water and in alcohol, but insoluble in ether and in petroleum ether. The authors subject the fresh plants to the action of the vapors of neutral liquids boiling below 100° C. This treatment kills the natural ferments, without the material coming into contact with the liquid. The plants are then dried, powdered, extracted with alcohol, 80 per cent., and the alcoholic extract is evaporated, in vacuo, without heat. The semi-solid extract is then kneaded under anhydrous ether, which removes chlorophyll and fat. The residual extracts are of different colors, according to their source. They are soluble in water, and the authors claim that they contain all the active principles of the fresh plant in an unaltered state. Pharm. Journ. and Pharmacist, Sept. 18, 1909, 365; from Journ. de Pharm. et Chim. 30 (1909), 186.

Solid Extracts.—Valuation.—In the course of an interesting review of the pharmacological and chemical history of tansy (Tanacetum vulgare), H. Matther and H. Serger direct attention to the insufficiency of determining the value of many solid plant extracts on the basis of alkaloidal or glucosidal constituents and, per contra, the possibility of arriving at a more satisfactory valuation of the same by extending the field of research and observation to constituents of a more or less indifferent or inactive nature, such a tannins, resins, fats and the like, which when determined according to a general scheme might yield constants that admit of drawing definite conclusions. Thus, for example, the authors have recently determined in

Tanacetum Extract, prepared from the flowers of the plant by extraction with alcohol, certain resins, fats, tannins, bitter substances, and alkaloidal bodies, without, however, reaching any definite conclusions, owing to the impossibility of isolating the bitter principles and alkaloidal bodies quantitatively. The valuation of such extracts therefore becomes possible only on the basis of the more or less indifferent constituents, which may serve as constants for the particular extract under a uniform scheme of examination adapted to solid extracts in general. Such a scheme is described by the authors, and has been applied in three parallel experiments to the extract of tansy under examination, with the following results:
Extract of Belladonna.

Substances insoluble in water...... 34.17 35.28 34.60
Alcohol—soluble resin............. 12.44 12.51 11.85
Ether—soluble resin.............. 1.717 1.729 1.84
Fat.......................... 6.615 6.934 6.821
Fatty acids..................... 2.930 2.603 2.681
Unsaponifiable matter.......... 1.617 1.826 1.535
Substances precipitable by solution of
lead subacetate............... 20.07 20.36 21.11
Water........................ 7.25 — —
Ash............................ 13.61 — —
Acid number.................... 3.9 — —
Tannins.................... 11.528 — —

—Apoth. Ztg. xxiv (1909), No. 64, 575-577.

Purified Extracts—Preparation from Aperient Drugs.—Knoll & Co. have patented a method for removing the inert constituents of certain aperient drugs (thus rendering them more effective and more acceptable to the stomach) by treating the alcoholic extraction with ether, and adjusting the ethereal extract obtained with milk sugar to a definite pharmacological activity. So, for example, 1 Kgm. of rhubarb root is extracted with two successive portions of 5 liters of alcohol, and the extract, either at once or after concentration, is treated with ether as long as a precipitate is produced. This is removed by filtration, the ether and alcohol are distilled off from the filtrate, and the residue is adjusted to the required strength with milk sugar. The yellow powder so obtained, although not quite soluble in water, is perfectly soluble in diluted alkalies, forming a deep red solution.—Pharm. Ztg., liv (1909), No. 89, 880.

Solid Extracts—Preservation in Collapsible Tubes.—A writer (H in B) suggests the preservation of solid extracts that are but rarely called for in collapsible tubes lined with wax paper. The extracts are thus protected from the action of the air, retain their plastic condition, and are dispensed with economy and cleanliness.—Pharm. Ztg., lv (1910), No. 38, 388.

Solid Extracts—Preservation in Screw-cap Jars.—Frommann directs attention to the use of screw-cap glass jars, which are obtainable in all desirable sizes, as preferable to the collapsible tubes suggested by “H in B.” Contact with the metal of the screw-cap is prevented by interposing a disc of corkwood, or thin linoleum. When the quantities of extract are small, the diminutive jar is encased in an ordinary shop jar, with loose cover, the interior (bottom) lined with a pad of felt. With these precautions the extract is protected from the influence of air and dust, and is conveniently available in good condition until completely consumed.—Ibid., No. 45, 459.

Extract of Belladonna, Fr. Pharm.—Alkaloidal Strength.—An extract of belladonna prepared by André according to the process of the French
Pharmacopoeia, 1908, gave 2.28 per cent. of alkaloids calculated on the dry extract. Two commercial extracts yielded 2.14 and 2.37 respectively. The French Pharmacopoeia, 1908, does not give any alkaloidal standard for this extract. The Belgian, Swiss, and German Pharmacopoeias require 1.5 per cent. The requirements put forward by Grimbert and Warin, 4 to 5 per cent., are evidently unattainable at present. Pharm. Journ. and Pharmacist, Oct. 9, 1909, 451; from Journ. de Pharm. et Chim. 30 (1909), 249.

Bitterless Extract of Cascara Sagrada.—Preparation with Zinc Oxide.—The “Journal de Pharmacie d’Anvers” publishes a method for preparing bitterless extract of cascara sagrada in which zinc oxide is satisfactorily used in place of calcined magnesia. 1000 Gm. of powdered cascara bark and 80 Gm. of zinc oxide are intimately mixed, sufficient hot water is poured on the mixture to well cover it and it is allowed to stand 8 or 10 hours at 60° to 70° C. After cooling it is expressed, and the maceration with hot water is repeated several times in the same way. The united infusions are filtered and evaporated in a vacuum to dryness, the yield being about 23 per cent. of a brown, scarcely hygroscopic extract, readily soluble in water, and completely free from bitterness. Pharm. Ztg. liv (1909), No. 61, 594.

Extract of Kola, Fr. P.—Official Caffeine Content not Attainable.—J. Warin says that the official powdered kola of the Fr. P. is required to contain 1.25 per cent. of caffeine, and the official extract, prepared with 60 per cent. alcohol, should be obtained in a yield of about 12 per cent. of the original powder, and is required to contain at least 10 per cent. of caffeine. Operating strictly by the official directions with powdered kola containing 1.8 per cent. of caffeine, 14.7 per cent. of extract was obtained which contained 5.4 per cent. of caffeine only. Another portion of the same extract which had been prepared without the filtration directed, yielded 16.5 per cent. extract containing, however, 7.75 per cent. of caffeine. It is apparent from this that a portion of caffeine is removed from the aqueous residue, remaining after distilling off the alcohol, if, as directed, it is submitted to filtration before evaporation.—Pharm. Journ. and Pharmacist, June 18, 1910, 760; from Journ. de Pharm. et Chim., 1910, 7, 543.

Licorice Extracts—Analysis of Commercial Sorts.—Ernest J. Parry contributes an interesting and exhaustive paper on the “Licorice-juice of Commerce,” in which he points out that licorice varies so enormously according to the country in which it is grown, and even the locality in the same country, that it would be very inadvisable to attempt to lay down any standard figure for the commercial product. The principal variation is in the amount of glycyrrhizin contained in the root, which may be twice as much in a root grown in one district as in one grown elsewhere. Nevertheless, these juices (extracts) may be divided into three distinct species,
viz., (1) Calabrian juice, the type of the ordinary edible juice, containing 10 to 15 per cent. of glycyrrhizin, and used in the manufacture of stick licorice; (2) Anatolian juice, containing from 17 to 25 per cent. of glycyrrhiza, but too bitter to be palatable. This is the type of juices (forming the pure black extract), used in manufacturing, but never made into stick licorice. (3) Sweet Spanish juice, frequently containing 6 per cent. or less of glycyrrhizin, and not considered valuable. The author has prepared extracts of licorice from parcels of authentic root from the places of their origin, which, by the process of analysis employed and described in detail, fully verified the authenticity of the samples described in the following tables:

From an examination of numerous samples of extracts made by the author from different roots, he was unable to find any licorice juice of authentic origin which differed materially from the above described types.

Regarding licorice extracts from France and Belgium, in which countries, so far as the author has been able to ascertain, no licorice root is grown, the roots or block juice are imported, and the sticks are moulded, usually with the addition of saccharine matter. From reports of the White Cross Congress, together with his own examination of a large number of doubtful or adulterated samples, of which the following are typical, it appears that the greater part of the French and Belgium licorice-juice is a mixture of pure juice and added saccharine matter.

In these samples the low ash, high amount of matter soluble in water, low starch and gummy matter and high sugar values are significant.—Chem. & Drugg., Jan. 1, 1910, 21–22.

**Extract of Licorice.—Contamination with Metallic Copper.**—Fr. Wandersleben directs attention to the not infrequent occurrence of particles of metallic copper, plainly visible under the lens in some instances, in others embedded in the mass. He attributes its presence to attrition and scratching during the stirring of the mass and removal from the copper kettles in which it is prepared. Pharm. Ztg. lv (1910), No. 6, 58.

**Malt Extract.—Requirements of a Properly Prepared Article.**—In the mashing of malt, as is well known, the starch undergoes hydrolysis under the influence of the diastase, and is transformed partly into maltose and partly into maltodextrin. Max Hamburg points out particularly that this formation of maltodextrin takes place under all circumstances, and that in his experience it never falls short of 10 per cent. of the maltose produced at the same time. Other important constituents of malt extract are the proteins which have been rendered soluble by the action of the malt peptase, and which for the most part belong to the class of albumoses. Further, in a properly prepared malt extract there will be found a quantity of active enzyme, principally diastase, and, whether the extract is intended
for medicinal use or for dietetic purposes, all of these constituents—maltose, dextrin, proteins, and diastase—ought to be present in due proportions. In examinations of a large number of perfectly pure malt extracts, the dextrin figure never dropped below 3.2 per cent. and usually ranged from 9 to 14 per cent., rarely above, and it contained from 5 to 7.8 per cent. of protein, together with 1.5 to 1.8 per cent., of mineral matter, in the dry solids. The diastase efficiency of a malt extract should not fall below 3.8 Mgm. of maltose with one gramme of extract when acting on starch paste by one of the methods in vogue.

Adulterations of malt extracts are increasingly frequent. The principal adulterants found by the author have been materials containing dextrose, such as starch syrup, molasses, etc., and some malt extracts have been found to consist solely of saccharified potato starch with the addition of a little malt. In view of the generally unsatisfactory character of commercial malt extracts, the author considers it very desirable that uniform methods for their examination be established.—Pharm. Journ. and Pharmacist, July 31, 1909, 133.

Malt and Cod Liver Oil—Commercial Variation.—E. F. Harrison contributes an instructive article on variations observed in extracts of malt with cod liver oil on the English market. His examinations comprise nine popular brands, four supplied by large retail concerns, and six supplied by manufacturing houses as "own name specialities" to pharmacists. The latter contained from 1.5 to 10.3 per cent. of oil only, and by the author's method (described in Proceedings 1909, 76) showed a diastasic value of from 9 to 150, with a content of from 59.2 to 72.9 per cent. of maltose in extract. The second lot mentioned showed: Oil, 2.1 to 10.1 per cent.; maltose, 55.9 to 69.1 per cent.; diastasic value, 10 to 104. The first mentioned (nine samples) gave: 3.6 to 33.8 per cent. of oil, 53.6 to 75.2 per cent. of maltose, and a diastasic value of 5 to 776. The author describes simple methods for determining the oil and maltose in the preparation.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 335-337.

Extractum Malti cum Oleo Morrhus is suggested for inclusion in the N. F. by Hugh Craig, who gives a formula in the "Proceedings," 1909, 1154.

Extract of Meat—Presence of a Basic Constituent in Large Proportion.—R. England says that among the constituents of Liebig's extract of meat a base of the formula C₁₇H₃₃NO₃ occurs in large quantities, for which he suggests the name—

Carnetine. From its reactions it is found that—(1) it contains a carboxyl group; (2) it contains a hydroxyl group in the α-position with regard to the carboxyl; (3) it contains a trimethylamine residue bound to the carbon atom which is in the γ-position with regard to the carboxyl group. Thus it is an α-oxy-γ-trimethylaminobutyric acid of normal struc-
ture. Its chloride has the formula Cl(CH)₃N.CH₂.CH(OH).COOH.

Albumen-meat Extract—A Stable Substitute for Natural Meat Juice—
Reviewing the historical facts connected with the introduction and uses of fresh meat juice, following the suggestion of Liebig (in 1854), of an infusion of fresh meat as a stimulant-nutrient for the sick, a writer, over the signature "K. W.," recommends the following formula for a concentrated albumen-meat extract, which keeps well and efficiently replaces all the substitutes for meat juice that have heretofore been prepared, as well as the freshly-prepared meat juice prepared by expression. The necessary materials are a good meat extract and carefully-prepared dried-egg albumen—600.0 Gm. of the dried albumen, in pieces, and 600.0 Gm. of cold well-water are placed in a porcelain or stoneware vessel and allowed to stand about 18 hours at the ordinary temperature; then solution is effected by gentle stirring and the egg-membrane is removed by straining the solution through fine-meshed gauze. To the strained liquor 800.0 Gm. of meat-extract are added and after one to two hours mixed by gently stirring, to avoid formation of froth. The preparation so obtained has the consistence of a thin extract, sufficiently fluid to be poured from the container, and is not changed on exposure for two weeks in the incubator at 37° C. It contains 30 per cent. of albumen. If desirable, celery salt or some other condiment may be added to correct the taste.—Apoth. Ztg., xxv (1910), No. 39, 348.

FLUIDEXTRACTA.

Fluidextracts—Question of Preparation by Retail Pharmacists.—Frederick J. Blumenschein discusses a question which cannot be impressed too strongly upon pharmacists, namely the question of practicability for the retail druggist to prepare in his own laboratory the fluidextracts which he is called upon to dispense. He says that the manufacturers have so repeatedly impressed upon the druggist his (the druggist's) inability to make and assay his own fluidextracts, that he has come to believe in it to such an extent that he buys all his fluidextracts with the firm conviction that time and money are saved. But, the author contends that, with two possible exceptions—senna and licorice—all the U. S. P. fluidextracts can be made in quantities of one-half pound upward cheaper than they can be purchased. The strongest argument the salesman can offer is that his fluidextract does not precipitate; this is not true, for all of them precipitate upon aging and exposure to light and air. But the large manufacturer carefully ages and filters his compounds—this requiring from two months to a year. The author follows these preliminary remarks with some brief practical suggestions which will repay consultation in the original paper, which appears in Proc. Penna. Pharm. Assoc., 1909, 187-189.
Fluidextracts.—Value of Glycerin as Solvent and Preservative.—At the meeting of German Naturalists and Physicians in Salzburg, 1909, Dr. Richard Firlas described a series of experiments undertaken with the object of ascertaining the value of glycerin as a solvent for the active constituents of drugs in the preparation of fluidextracts by percolation, and the influence of glycerin on their stability, etc. Selecting cinchona, kola, condurango, hydrastis and ergot as typical examples, he arrived at the following conclusions: The presence or absence of glycerin in the menstruum does not affect the amount of alkaloid or glucoside in the fluidextracts from any of these drugs, the differences, if any, being so small as to be quite negligible; but their stability is affected to a greater or less extent, the alkaloid or glucoside being diminished more rapidly in fluidextracts prepared without glycerin than in those prepared with a menstruum containing glycerin, this diminution being greater in the case of cinchona and kola, less in condurango, scarcely appreciable in hydrastis, and inappreciable in ergot. The same rule holds good for the total residue of evaporation, which diminishes more rapidly in the fluidextracts prepared without glycerin than in those prepared with glycerin. In either case, however, the diminution of alkaloid, glucoside or total extractive is relatively greatest during the first year, is then gradually minimized, and finally remains constant; but in the case of the fluidextracts prepared with glycerin the diminutions in alkaloid and glucoside values fluctuate during the first three years within such narrow limits as to become practically negligible. On the basis of these observations the fluidextracts of cinchona and kola should be made with glycerin, those of condurango and hydrastis are advantageously made with glycerin, and in fluidextract of ergot glycerin is not necessary.—Apoth. Ztg., xxiv (1909), No. 77, 721–722.

Fluidextracts.—Preparation by Extraction under Pressure.—L. Kroeber, after discussing the limitations and imperfections of the percolation methods in use for preparing fluidextracts, records the results of comprehensive experiments made by the method of extraction recommended some years ago (1904) by Bruns, who described an apparatus for this purpose consisting in its essentials of a cylindrical hydraulic press. Although experiments made by J. Herzog in 1905, in the pharmaceutical Institute of the University of Berlin, by Brun's method, failed to lead to satisfactory results, Kroeber now finds that by observing certain conditions—small quantities of the solvent, 3-4 successive expressions, etc.—fluidextracts are obtainable by this method, which meet all requirements, and which yield a dry residue of evaporation only inappreciably less than that yielded by fluidextracts made by percolation. Pharm. Zentralh, 51 (1910), No. 3, 41–47.

Fluidextracts.—Identification.—H. M. Gordin summarizes the points brought out by him in his paper on the indentification of fluidextracts
read before the Chicago Branch of the A. Ph. A. in 1909. This summary appears in the "Proceedings," 1909, 886-888.

**Fluidextract of Buckthorn Berries—Preparation.**—George M. Beringer and George M. Beringer, Jr., recommend the following method of preparation for a fluidextract of buckthorn berries: Add 1000 Gm. of the ground berries to 5 liters of boiling water, allow to infuse for two hours, and express; then infuse the dregs with 3 liters of boiling water in the same way and express; mix the expressed liquids, and evaporate to 750 Cc. When cold, add 250 Cc. of alcohol; allow the mixture to stand a few days, filter, and wash the filter with sufficient of a mixture of 1 volume of alcohol and 3 volumes of water, to make 1000 Cc. A satisfactory preparation can also be made by percolation, using diluted alcohol, in the usual way. Percolation with weaker alcohol was found impracticable owing to the gummy character of the drug.

**Fluidglycerate of Buckthorn Berries** can be prepared by the type process proposed by one of the authors (see Proceedings 1908, 981), but the percolation is very slow and tedious.—Amer. Journ. Pharm., July, 1909, 325.

**Fluidextract of Cascara Sagrada—Use of Ammonia to Effect More Complete Extraction of the Bark.**—Charles Symes finds that when fluidextract of cascara sagrada is prepared according to the formula of the B. P., the addition of ammonia water to the marc after the bark is exhausted by water alone, and then the continuation of percolation with water, results in the extraction of additional aperient matter. He has utilized this observation in the preparation of this fluidextract from 28 lbs. of bark, modifying the process also by using chloroform water instead of pure water to apparent exhaustion; then following this by the addition of 2 gallons of chloroform water and 10 ozs. of liq. ammoniae, B. P., and continuing the percolation to obtain a second percolate, which was evaporated to 16 fl. ozs., added to the concentrated first percolate to which 2 pints of glycerin had been added during evaporation. This was then adjusted to the proper volume by the addition of diluted alcohol.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 319-320.

**Fluidextract of Rhamnus Purshiana—Characters of Identity.**—In connection with an elaborate investigation of the bark of Rhamnus Purshiana and R. Frangula, L. Kröber describes the following characters by which the identity and quality of a properly-prepared fluidextract of Rhamnus Purshiana may be established: The fluidextract should be dark-red brown, should have a peculiar bitter taste, and should form a turbid liquid when mixed with 10 parts of water, while the precipitate produced thereby should be yellow-brown, but by no means coffee- or chocolate-brown. The specific gravity of the fluidextract at 15° C. should be from 1.060 to 1.070, never less than 1.050, and the dry residue of evaporation should
FLUIDEXTRACT OF HYDRASTIS.

87

weigh at least 20 per cent. of the weight of fluidextract taken. The mineral constituents (ash) should not exceed 1.2 per cent. If 1 Cc. of the fluidextract, diluted with 1 Cc. of water, is shaken with 10 Cc. of ether, and 5 Cc. of the clear yellow ether-layer are shaken with 5 Cc. of water and a few drops of ammonia, the aqueous layer should acquire a deep cherry-red color. The filtrate of a mixture of 1 p. of the fluidextract and 9 p. of water should give with solutions of tannin, of corrosive sublimate, of ferric chloride, of ammonium molybdate, and of acetic acid, an immediate turbidity, followed by the formation of precipitates in the course of some time.—Pharm. Ztg., lv (1910), No. 37, 376; from Pharm. Praxis, 1910, No. 1.

Fluidextract of Ergot—Chemical Assay.—John R. Rippeto is has subjected some specimens of fluidextract of ergot, which he had tested during the past three years by observing their action on the cock's comb, to examination by the "benzol extract" method recently proposed by Dr. Horatio C. Wood, Jr. (see Proceedings 1909, 151), and communicates the results in some detail. While, as a matter of course, no previous assays of the benzol extracts could be made—the process being unknown—it is noteworthy that they contain a proportionally lower amount of extract according to age, the quantity varying from 0.14 Gm. in 100 Cc. of fluidextract made in 1907 to 0.56 Gm. in 100 Cc. of extract made in 1909. It is noteworthy also that larger doses of the preparations were required after eight months' ageing to produce the desired action upon the cock's comb.

Fluidextract of Hydrastis—Simplification of G. P. Method of Assay.—Prof. E. Rupp has worked out a simplified method for the assay of fluidextract of hydrastis, G. P., for which he claims absolute reliability. In a tared Erlenmeyer flask of about 125 Cc. capacity, 10 Gm. of the fluidextract and 20 Gm. of water are evaporated by moderate boiling to from 9 to 11 Gm., to eliminate the alcohol completely. When cool, the liquid is acidulated with 1.5 Gm. diluted HCl, and adjusted with water to 20 Gm. Now 1 Gm. of talc is added, the contents of the well-corked flask are vigorously shaken during one minute, filtered, and 10 Gm. of filtrate collected in a 100 Cc. flask, in which it is well shaken with 4 Gm. of spirit of ammonia and 20 Gm. of ether during several minutes. Then 20 Gm. of petroleum ether, b. p. 40°, are added, the mixture is again thoroughly shaken, and then again after the addition of 1.5 Gm. of powdered tragacanth until the gum balls together and the supernatant liquid is clear. Of this, 32 Gm. are weighed into a tared beaker, the solvent is evaporated on a water bath, and the residue dried to constant weight. This residue represents the alkaloidal content of 4 Gm. of fluidextract; consequently multiplication of the ascertained weight by 25 gives the percentage of hydrastine in the sample.—Apoth. Ztg., xxiv (1909), No. 98, 922-923.
GLYCERITA.

Fluidglycerates have been the subject of further study and experimentation by George M. Beringer, who reports the results of his recent observations in a paper printed in the Proceedings, 1909, 1909-1014.

Glycerinum Acidi Borici, B. P.—Precautions to be Observed in its Preparation.—T. Hatfield Dyson says that no preparation so well repays a scrupulous attention to the cleanliness of the utensils as glycerin of boric acid. A perfectly clean porcelain or enameled dish and a glass rod should be used. The use of "finely powdered" acid is both unnecessary and undesirable. The crystals will serve equally well, and are much cleaner than the powder. The preliminary heating should be strictly followed, and the acid added in small portions, with constant and vigorous stirring. If the temperature is maintained at about 290° F. much time will be saved, and there is little danger of the temperature rising unduly until all the acid has been added if the mixture is vigorously stirred. After this the temperature slowly rises, and when the temperature of 302° F. is reached the weight is approximately one-eighth above that to which it should be evaporated. If, therefore, the official directions were amended, "continue the application of heat . . . until the product is reduced to 11 ounces, then add 9 ounces of glycerin," a preparation would be obtained having the physical character that is required by the physician, while considerable time would be saved in the process. The reduction to 10 ounces, as now required, is quite tedious.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 700.

Glyceritum Iodi is recommended by Franklin M. Apple for the purpose of conveniently and expeditiously preparing the ointment. A formula is given in "Proceedings," 1909, 1132-1133.

Glycerinum Plumbi Subacetatis B. P.—Modification of Process.—T. Hatfield Dyson observes that the directions of the B. P. to evaporate the prescribed quantities of ingredients for glycerin of lead subacetate to a given weight and a specific gravity of 1.48 cannot be uniformly complied with, because the weight and specific gravity are not necessarily equivalent. He therefore suggests that the directions be amended to read: Liquor plumbi subacetatis fortis, 20 fl. ozs.; glycerin, 20 fl. ozs. Evaporate to the weight of 33½ ozs., or sp. gr. 1.48.—Pharm. Jour. and Pharmacist, Dec. 4, 1909, 700.

INFUSA ET DECORTA.

Infusions and Decoctions.—Pharmacopoeial Definitions and Directions.—Dr. Bulenheim, although considering the present definition and directions for preparing infusions and decoctions an improvement on those given in previous editions of the G. P., suggests that omitting "decoctions" as an obsolete form of preparing medicinal extractions, the article on infusions might with advantage be formulated as follows:
"To prepare an infusion the drug, comminuted if necessary, is covered with (cold) water in a suitable vessel, and heated for at least 15 minutes in a water bath, stirring repeatedly. Moderately fine or coarsely comminuted drugs must be heated half an hour. The liquid is then strained while hot, unless the nature of the drug demands the contrary, and if necessary expressed."

While in the case of some drugs—digitalis, ergot, etc., it is imperatively necessary to strain the infusion while hot, in others, notably condrango, it is equally necessary that the infusion is allowed to cool for some time before straining it from the dregs. The author also suggests the following general directions for preparing.

Macerations ("Aussüge" = Extractions): "The drug, comminuted if necessary, is covered with the prescribed liquid and allowed to stand without the application of artificial heat, stirring occasionally. It is then strained and if necessary expressed."—Pharm. Ztg., lv (1910), No. 32, 325.

Concentrated Infusions—Rational Preparation.—C. Hartleb discusses the question of admitting concentrated infusions as substitutes for freshly prepared infusions, with particular reference to the infusions of digitalis and of ipecac, and arrives at the conclusion that by adopting a rational method of preparation such concentrated infusions, possessing stability and reliability, are readily made. Taking, for example,

Concentrated Infusion of Digitalis, the author says that the glucosides digitoxin, digitonin and digitalin, are either completely or almost completely insoluble in water, and that an infusion prepared with water alone can contain only a very small proportion of these, admittedly the active constituents of digitalis leaves. But if a small percentage of alcohol is used, a 1:20 infusion is readily obtained, containing practically the entire glucosidal contents of the leaves, by adopting the following formula and procedure; 20 Gm. of fresh digitalis leaves (containing at least 0.3 per cent. digitoxin) are introduced into a 500-Cc. flask with 80 Gm. of 90 per cent. alcohol and allowed to stand one hour after thorough shaking. Then 300 Gm. of boiling distilled water are gradually added to the contents of the flask, and the whole is allowed to stand, with frequent shaking, for 12 hours. The mixture is then strained, expressed, filtered and the filtrate adjusted to 400 Gm. with a mixture of alcohol and water in the proportion of 1 and 4. So obtained, the concentrated infusion possesses unlimited stability, and represents the total activity of the digitalis leaves used. In the case of

Concentrated Infusion of Ipecacuanha the conditions are practically the same. The active principles, emetine and cephaeline, are only sparingly soluble in water, but readily soluble in alcohol. It suffices, however, to use a small percentage of alcohol for the menstruum (=15 per cent.)—Pharm. Ztg., liv (1909), No. 74, 726.
Infusion of Digitalis—Preservative Effect of Small Percentages of Alcohol.—In continuation of his valuable researches on digitalis and its preparations, Dr. C. Focke has studied the effect of adding small percentages of alcohol to the infusion with the object of correcting the taste and improving its stability. Basing his conclusions on an experience of several years with physiologically tested and assayed infusions of digitalis, he found that the addition of 5 per cent. of alcohol renders the infusion more palatable and reasonably stable within certain limits, and if as much as 10 per cent. of alcohol is added, he has found it effective within 5 or at most 10 per cent. of its original activity after keeping it for 9 months (including the winter months) in a warm place. An infusion treated with the same amount of alcohol and exposed in the spring of the year to the afternoon sun during 2½ months, had become somewhat lighter in color, but showed no greater diminution in physiological activity than the sample protected from light. For nearly two years Dr. Focke has employed infusion of digitalis containing 5 per cent. of pure alcohol in his practice, and found it to be satisfactory in every respect, and particularly as regards stability and tolerance.—Pharm. Ztg., liv (1909), No. 77, 757; from Caesar & Loretz’s Ber., Sept., 1909.

LINIMENTA.

Ammonia Liniment—Acidity of Oils a Desideratum.—Krekeler observes that in former years complaints of failure to obtain a satisfactory ammonia liniment were seldom made by the pharmacist, while modernly they are quite frequent. The liniment was then made with ordinary olive oil (ol. olivar. commun.) and there was no difficulty to obtain a handsome thick-liquid mass when the directions of the G. P. were followed. With the abandonment of the crude olive oil, prepared by more or less primitive methods and containing an abundance of free fatty acids, and the substitution by the Pharmacopœia of purer fixed oils, such as poppy oil, etc., the failures to prepare a satisfactory liniment have become numerous. This, the author maintains, is due to the very purity of the oil—its freedom from acids, and he therefore suggests the addition of olein to supply this deficiency. An excellent liniment is obtained, for example, with: Olein, 60.0; ol. papaver., 3900.0; liq. ammon. caust., 800.0. If too thick, this is readily corrected by the addition of a little water.—Pharm. Ztg., xv (1910), No. 14, 139.

Linimentum Cajuputi et Chloroformi Compositum is suggested for inclusion in the N. F. by Hugh Craig, prepared according to a formula which he gives in the “Proceedings,” 1909, 1154.

Vasolimentum Salicylatum 10 per cent.—Improved Formula.—Schnabel states that the formula for 10 per cent. salicylated vasoliment proposed for the G. P. V. requires the addition of alcohol to make it satisfactory, and
therefore recommends the following modification of the formula: Shake 10 p. salicylic acid with 5 p. absolute alcohol and add 85 p. vasoline. The preparation may also be made direct from the individual components, as follows: Mix 38 p. olein (redistilled), 38 p. liquid paraffin and 3.8 p. solution of ammon., sp. gr. 0.91, and add to this mixture a solution of 10.2 p. salicylic acid in 10.2 p. absolute alcohol.—Apoth. Ztg., xxiv (1909), No. 102, 959.

LIQUORES.

Volumetric Solutions of the U. S. P.—Metallic Silver as a Suitable Ultimate Standard.—Elias Elvove observes that the very prominent position given to volumetric analysis is in the U. S. P., and its almost exclusive use, wherever possible, in determining whether a given substance comes up to the required standard of purity, render it imperative that the most suitable ultimate standard be adopted for the necessary volumetric solutions. It is also obvious that in considering what substance might form a suitable ultimate standard for these solutions, we must place as of primary importance the readiness with which such substance is obtainable in a pure state, its stability under ordinary conditions, its possessing the necessary properties for admitting of its use in a volumetric process of proven accuracy, and finally, what likelihood there is of different operators obtaining such substance in different degrees of purity although working by the same method. After pointing out some of the objections to potassium bitartrate which is chiefly relied on as standard in the U. S. P., the author refers to the large number of substances that have from time to time been suggested and used for the same purpose, pointing out their deficiencies in some cases and pronouncing them unmistakable; arriving at the conclusion that the one substance that apparently meets all demand is “pure silver.” He says, that of all volumetric processes at present known, there is probably not one that excels in elegance or accuracy the well-known Volhard method for titrating silver by means of a thiocyanate solution. In fact, its advantages are so pronounced that Shutt and Charlton have even recommended its use in estimating the very small amounts of chlorine in potable waters, in preference to the standard chromate method. Moreover pure metallic silver is obtainable with comparative ease, and by its adoption as the ultimate standard for the required volumetric solutions of the U. S. P., as he confidently advises, the way would be paved for leaving such standard supplied from one source, thus making the uniformity absolutely complete. Amer. Journ. Pharm. May, 1910, 203–211.

U. S. Volumetric Solutions are discussed by A. H. Clark in reference to their keeping qualities in a paper which appears in the “Proceedings,” 1909, 874–879.

Sterile Solutions—Preparation by Pharmacists.—Clarissa M. Roehr makes some practical observations on, and gives directions for, preparing
sterile solutions, concluding with the following remarks which merit the attention of pharmacists: "The question is often asked, Can pharmacists profitably dispense sterilized solutions? There seems but one answer. The apparatus required is very simple, and when physicians see that pharmacists are prepared to do this work, it is very evident that it will add to their professional standing and also to their commercial interests."—Pacific Pharm., Dec., 1909, 249-250.

_Sterilized Solutions—Influence of the Components of Glass upon them._—Lesure has made some interesting observations concerning the influence of the components of the glass containers of sterilized solutions, his investigations leading to the following conclusions: For solutions containing hydrolyzable compounds (of the type of cocaine hydrochloride), vials of _neutral_ glass must be used, _i. e._, such glass as under the ordinary conditions of sterilization in the autoclave do not separate any alkali. Such suitable glasses are the Jena (Schott & Co.), the Cologne (Ehrenfeld) and the Serax glasses.

For solutions of salts forming insoluble compounds (phosphates, arsenates, etc.), calcium-free glasses, containing instead aluminum, zinc or magnesium silicate, should be used.

For substances less susceptible to decomposition, such as sodium cadoxylate, methyl arsenate, strychnine salts, mercury salts, etc., glasses showing faint alkalinity, under the conditions above mentioned, may be employed.

For solutions of chlorides, bromides and iodides, glass containing lead must be avoided.

The ideal glasses, of course, are those of quartz, which combine all the advantages of the others, but are practically excluded from consideration on account of their high cost.—Pharm. Ztg., lv (1910), No. 18, 181; from Journ. de Pharm. et de Chim., 1910, Nos. 2 and 3.

_Sterilized Gelatin Solution.—Preparation for Ampuls._—"E. S." gives a detailed description of the method of preparing sterilized gelatin solution for ampuls as practiced in the laboratory of K. J. Kresling, in St. Petersburg: Using only the best quality of gelatin, 100 Gm. are dissolved in 1000 Gm. of water by heat in a porcelain or enameled vessel. If the resulting solution is acid it must be neutralized with alkali. When cooled to 40°-45° C., the white of one egg, beaten with several times its volume of water, is added and the mixture is heated in a flask in a current of steam for 20 to 25 minutes, and then for 5 to 8 minutes, under pressure in the autoclave at 103°-105° C. This coagulates the albumen completely and the solution may now be filtered, which is best accomplished in the autoclave under a gentle current of steam. The clear filtrate is now adjusted to 1000 Gm. and, if the proper conditions have been observed, should form a consistent jelly on cooling. After adding 0.8 per cent. of
sodium chloride, the hot solution is at once filled into ampuls (25 and 50 Cc. capacity), previously carefully cleaned and perfectly sterilized, and avoiding that the solution touches the walls of the neck, which would result in discoloration of the sealed end of the ampul. In order to assure complete sterility, the filled ampuls are subjected for two days to a temperature of 37° C. in the thermostat, during which exposure no colonies should be developed. Pharm. Ztg., liv (1909), No. 56, 551; from Pharm. Jour. (Russ.) 1909, 200.

Liquor Alumini Acetici—Formula Permitting the Sterilization of the Product.—K. J. Sooms recommends the following formula, a method for preparing a solution of aluminum acetate which may be sterilized without decomposition: 30 p. of pure alumin. sulph. are dissolved in 75 p. of distilled water and 13 p. of calcium carbonate, triturated with 20 p. of distilled water, are added, rinsing in the last portion of calcium carbonate with 5 p. more of water. The mixture is stirred frequently during 24 hours and then heated until CO₂ is no longer evolved; then 36 p. of acetic acid, of 30 per cent., are added, and the preparation is finished as usual. The product when heated to boiling becomes slightly opalescent, but perfectly clear again on cooling.—Pharm. Ztg., liv (1909), No. 86, 851; from Baltische Pharm. Monatsch., 1909, 95.

Liquor Alumini Acetici—Improved Manipulation.—Dr. Bulenheim points out that the usual method of preparing solution of aluminum acetate suffers from all the faults inherent to a saturated or supersaturated solution. Calcium carbonate and gypsum, held in solution by the carbonic acid evolved during the process of preparation, are gradually deposited and render the solution turbid. Employing ingredients of the right quality, the directions should be so changed that a more concentrated solution is preliminarily produced, stirring the mixture during the reaction until the evolution of gas is no longer perceptible. The mixture is then allowed to stand several days, so that the calcium salts may completely precipitate. If the solution is then filtered and diluted to the proper strength a perfectly stable preparation is obtained, colorless and permanently clear. Furthermore, the author points out that the variable quality of the aluminum sulphate of the market is responsible for the unsatisfactory quality of the solution. He therefore suggests that a

Liquor Alumini Sulphurici be adopted in the G. P. of the strength 1 : 2 or 1 : 3, to be directed in place of the dry salt now official, which suffers from the fact that it contains water in variable proportions, whereas for the preparation of solution of aluminum acetate it should be anhydrous.—Pharm. Ztg., lv (1910), No. 32, 324.

Burow’s Solution is the subject of an interesting paper by Otto Raubenheimer, in which he discusses the origin of this preparation, and its relation to the liquor aluminii aceti of the different authorities. The paper appears in the “Proceedings,” 1909, 1036–1044.
Alkaline Antiseptic Solution—Bleaching and Spontaneous Restoration of Color.—Prof. H. V. Arny mentions that some specimens of alkaline antiseptic solution made by different students of the Cleveland College of Pharmacy and stored in a cupboard during about six months were found very much faded, some being almost colorless. One of the bottles being opened, the color was completely restored within half an hour, and each of the bottles opened since have in like manner resumed their original color. The author is unable to account for this peculiar action.—Proc. Ohio State Pharm. Assoc., 1909, 40.

Liquor Antisepticus Alkalinus Ruber is the distinctive name given to a formula regarded as an improvement of that for the alkaline antiseptic solution now official in the N. F. The improved formula is given in the "Proceedings," 1909, 1137-1138.

Solution of Chlorinated Soda—Improved Process—Having found the U. S. P. method for the preparation of solution of chlorinated soda inadequate to yield a solution containing about 6 per cent. available chlorine, Elias Elvove, in search of an available method, found the process of Graebe, which depends upon the direct action of chlorine on sodium hydroxide solution, to serve excellently, the chlorine being generated from the hydrochloric acid by reaction with a permanganate (in Proceedings, 1903, 824). Graebe found that by employing a slight excess of the alkaline solution the stability of the solution is much increased. Moreover, that the amount of chlorine produced by means of a given quantity of permanganate is quantitative. From the data so obtained, Mr. Elvove has developed the following process for a solution of chlorinated soda containing 6 per cent. of available chlorine: 27.3 Gm. of potassium permanganate are placed into a distilling flask of about 300 Cc. capacity, fitted with a bi-perforated stopper, one of the perforations for the reception of a separating-funnel containing 175 Cc. of strong (33 per cent.) hydrochloric acid, the other for the delivery tube of the generated chlorine. This tube is connected with a small wash-bottle containing about 50 Cc. of water, and the wash-bottle in turn delivers the gas into a narrow-mouthed measuring cylinder containing a solution of 50.75 Gm. of sodium hydroxide in 419.25 Gm. of water, and almost filling it. When all the connections are made, the stop-cock of the separating funnel is turned so as to let the hydrochloric acid fall slowly in drops on the solid potassium permanganate in the flask—this being, of course, easily regulated. When the current of chlorine is observed to slow down, heat is applied to the flask and continued until the gas only very slowly bubbles through the wash-bottle, when the receiving cylinder is disconnected and the process is ended. In the experiment, described in detail, the increase in weight of the alkaline solution was 29 Gm., indicating 5.81 per cent. of chlorine.—Amer. Journ. Pharm., April, 1910, 161-166.
Solution of Hydrogen Dioxide.—Presence of Chlorine.—In view of the omission of a test for chlorides and free chlorine in the proposed purity tests of the G. P. for solution of hydrogen dioxide, Dr. Langensiepen calls attention to his experience that this solution frequently contains large quantities of chlorides and so much free chlorine that its presence manifests itself by the odor. A proper and exact test for free chlorine should therefore be included in the official tests of the G. P. Apoth. Ztg., xxv (1910), No. 24, 201.

Liquor Picis Carbonis.—Otto Raubenheimer directs attention to the confusion existing in regard to this preparation, which is also (and more generally) known as “Liquor Carbonis Detergens,” owing to the difference in alcoholic strength of the tincture of quillaja prescribed by different authorities. The paper is printed in the “Proceedings,” 1909, 1031-1035.

Liquor Potassii Arsenitis has been examined by A. B. Lyons with the object of ascertaining the extent of the gradual oxidation to which this solution is subject under ordinary conditions. This paper appears in the “Proceedings,” 1909, 904-905.

Solution of Sodium Arsenate, G. P.—Simple Method of Determining the Arsenic Acid.—Referring to and reviewing the various methods that have been proposed for determining the H$_2$AsO$_4$ content in the liq. natrii arsenici of the G. P., E. Lukenow recommends the following simplified method: 10 Cc. of the solution are pipetted into a glass-stopped flask, 3 Gm. of potassium iodide and 20 Cc. of concentrated hydrochloric acid are added, mixed, and allowed to stand 10-15 minutes (not longer). The neck of the flask is then rinsed with about 20 Cc. of water, to wash down any adhering iodine liberated by the reaction, and the iodine is titrated in the usual manner with $\frac{N}{10}$ solution of thiosulphate, with or without the use of starch paste as indicator. The reaction is expressed by the equation: $\text{H}_2\text{AsO}_4 + 2\text{HCl} + 2\text{KI} = \text{H}_2\text{AsO}_3 + 2\text{I} + 2\text{KCl} + \text{H}_2\text{O}$. The solution containing 1 per cent. of anhydrous arsenate, 10 Cc. should require 10.7-10.8 Cc. of $\frac{N}{10}$ solution of thiosulphate, corresponding to a purity of 99.5-100 per cent.—Apoth. Ztg., xxv (1910), No. 15, 122.

Sodium Hypobromite Solution—Convenient Method of Preparation for Urea Determinations.—To obviate the inconvenience attending the use of sodium hypobromite as usually made, A. Job and Dr. Clarens suggest the use of sodium hypochlorite and potassium bromide. The latter, treated by the hypochlorite, is very rapidly converted into hypobromite, so that eau de Javelle added to potassium bromide reacts on urea exactly in the same way as the liquid prepared with sodium hydroxide and bromine. Eau de Javelle is very stable under proper conditions, while the solution of potassium bromide may be kept indefinitely. The quantities recommended are 1 Gm. of potassium bromide for 20 Cc. of eau de Javelle. The two are mixed five minutes before the estimation.—Pharm. Journ. and Pharmacist, Oct. 23, 1909, 507; from Journ. de Pharm. et Chim., Aug. 1, 1909, 100.
Mucilagines.

Mucilage of Acacia—Preservation by the Addition of 10 Per Cent. Alcohol.—"Dr. B. in D." regards alcohol as the best preservative for mucilage of acacia and does not consider its addition objectionable from a therapeutic standpoint, while pharmaceutically it presents certain advantages. The addition of 10 per cent. alcohol, it is true, occasions preliminarily a strong coagulum, which, however, disappears on shaking, or on standing. The author therefore suggests the adoption of the following formula in the G. P.:

"3 p. of acacia, washed with water, are dissolved in 6 p. of water and then shaken with 1 p. of alcohol until the coagulum produced is completely dissolved. Then strain."—Pharm. Ztg., lv (1910), No. 23, 232.

Mucilage of Acacia—Novel Method of Straining.—Of the many methods of straining mucilage of acacia that A. W. Bromley has tried, he finds the least troublesome that is practicable in an ordinary pharmacy is to force it through the muslin by the pressure produced by the expansion of air in the bottle. Dissolve a quantity in a wide-mouthed bottle so large that the gum and water only half fill it; when dissolved, remove the cork and cover the bottle-mouth with muslin very firmly tied, and stand the bottle in the coolest place available for half an hour or so. Then invert the bottle into a measure (or other suitable receiver) and put the whole in a warm place. The confined air within the bottle expanding will force out part of the mucilage. When the process stops, the bottle is again set upright in a cool place, and when quite cold inverted into the measure as before. The author does not consider the temperature of 80° or 90° F., to which the mucilage is exposed by this method, to affect it injuriously.—Pharm. Journ. and Pharmacist, July 3, 1909, 6-7.

Mucilago Salep.—Manipulation.—The ordinary method of preparing mucilage of salep presents difficulties to secure a product free from lumpy particles, which according to Dr. Bulenheim may be overcome by manipulation as follows: The finely powdered salep is sprinkled in small portions at a time on the surface of the total quantity of water directed, awaiting the complete immersion of the powder before stirring and adding the next portion. After all the powder has been added in this way, the mixture is heated with frequent stirring—the entire procedure requiring about 15 minutes. Pharm. Ztg., lv (1910), No. 33, 334.

Olea.

Iodine Oils.—Method of Preparation.—Remo Conradt has experimented with various methods for the preparation of iodine oils and recommends the method of Winternitz as being most satisfactory if carried out as follows: The calculated quantity of freshly prepared iodine chloride (CII) is dissolved in absolute alcohol, mixed with the oil (almond or se-
same are the best) and heated to 40°, shaking frequently. The alcohol is
then removed by the aid of a separatory funnel and the last portions are
driven off in a vacuum at 40° C. The iodine oil so obtained is colorless and
contains no free iodine. A 10–20 per cent iodine-sesame oil remains
unchanged when heated to 100°–110° C., while the 25 per cent. oil is not
changed at 100° C., but assumes color at 105°–110° C. Pharm. Ztg., liv
(1909), No. 97, 957; from Boll. Chim. Farm., 1909, No. 48.

Phosphorated Oil—Conditions Affecting Stability.—P. Bohrisch finds
that light, air and moisture have an unfavorable influence on the stability
of phosphorated oil, while rancidity and temperature have comparatively
little effect. Expressed oil of almond is preferable to all other fixed oils
for the preparation of phosphorated oil, because of its purity and practical
freedom from moisture, although a carefully prepared olive oil will also
answer well. The stability of the stronger phosphorated oils (1:100 or
1:200) is, however, quite limited. They may keep unchanged for sev-
eral months if preserved in full, carefully stoppered vials in a dark place,
but acquire prolonged stability by the addition of certain deoxidizing
agents, such as limonene or other terpenes (1 per cent.), or of ether or
alcohol (5 per cent.). The more dilute forms of phosphorated oils
(1:500 or 1:1000), on the other hand, possess considerable stability,
keeping well for half a year or more, even if the stopper is frequently
lifted during that period; but both the strong and the more dilute oils will
retain their phosphorus content unchanged for at least nine months, and
even a year, if the preservative additions are made as above indicated.
The most satisfactory stronger oil, however, from which suitable dilutions
may be made is obtained if paraffin oil is used in place of the vegetable
oil, and adding to this 5 per cent. of ether as preservative. The most
suitable strength for this is 1:200. The author gives explicit directions
for preparing the oil,* which may be consulted in Pharm. Ztg., liv (1909),
No. 87, 859–860.

Phosphorated Oil—Formula of the Hungarian Pharmacopoeia.—In
connection with the observations of Mr. Bohrisch, the following formula of the
Hungarian Pharmacopoeia is of interest: 94.5 ol. amygdal. dulc. and 10.0
natrium sulfuricum dilapsam are heated together for half an hour on the
water-bath, with frequent and vigorous shaking; then 0.5 dry phosphorus
is added and, excluding light, shaken until the luminosity of the phosphorus
ceases. Finally 5.0 alcohol (95 per cent.) are added. If 1 Gm. of phos-
phorated oil so prepared is shaken with 10 Cc. of 5 per-cent. copper sul-
phate solution, a dark brown emulsion is formed, which, after frequent
shaking, becomes colorless.—Pharm. Ztg., liv (1909), No. 97, 956.

* Mr. Bohrisch's results and observations, except as to details, are practically identical
with those described by Hugo Korte in 1908, which see in Proceedings 1909, 92.—Rep.
Lecithin-Guaiacol Injection—Formula.—R. Lethert recommends the following formula and manipulation for preparing a lecithin-guaiacol injection: About 12.0 Gm. of the best olive oil are heated with 6.0 Gm. of 95 per cent. alcohol on the water-bath until all the alcohol, and with it any water present in the oil, is evaporated. When cooled to about 40° C., 2.0 Gm. of this washed and dried oil are triturnated in a clean warm mortar with 1.0 Gm. each of lecithin (pur. Merck), and guaiacol (absol.), avoiding strong frothing as much as possible, and sufficient more of the oil is then added gradually until a total of 7.0 to 8.0 Gm. has been used. The solution is then strained into a clean and dry sterilized vial through a gauze filter, and sufficient more oil is passed through the gauze to make exactly 10.0 Gm. of solution. If the lecithin is perfectly fresh a clear solution is thus readily obtained; otherwise, Swedish filter-paper must be used in place of the gauze filter. The solution must not be violently shaken at any time to avoid frothing.—Pharm. Ztg., liv (1909), No. 87, 859.

OLEATA.

Hydrargyrum Oleatum, B. P. 1898—Question of Percentage.—J. Hatfield Dyson observes that the preparation of a 25 per-cent. (oxide) mercury oleate by the method of the 1885 Pharmacopoeia presents no serious difficulty, but the percentage question (of the oleate B. P. 1898? Rep.) is a stumbling block to some if, for example, unguentum hydrargyri oleatis, 5 per cent., is prescribed. This may be interpreted to mean 5 per cent. of mercuric oxide by some, or 5 per cent. of mercuric oleate by others.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 700.

Zinc Oleate and Zinc Stearate—Improved Formulas.—E. Fullerton Cook and P. C. Dosch, owing to the indiscriminate use of the titles, zinc oleate and zinc stearate, set forth some facts about these preparations and give experimental data with the object of establishing greater uniformity in their formulas, which they recommend to be as follows:

Zinci Oleas—Zinc Oleate.

Zinc sulphate .................................................. 47 Gm.
Soap (Castile), dry and powdered (or grated) ............... 100 Gm.
Distilled water, a sufficient quantity.

Dissolve the zinc sulphate in 2500 Cc. of distilled water and filter if necessary. Dissolve the soap in 1500 Cc. of hot distilled water and strain the solution through cotton. Warm both solutions to about 50° C. (122° F.) and pour the solution of the zinc salt slowly into the soap solution, constantly stirring. Collect the precipitate on a muslin strainer, wash it thoroughly with distilled water, and allow it to dry on the strainer, or on clean paper, protected from dust and without exposure to heat. Finally pass the mass through a fine sieve.
Zinci Stearases—Zinc Stearate.

Ammonia water (10 per cent.) .................. 50.2 Gm.
Stearic acid ................................ 88.5 Gm.
Zinc sulphate ................................ 44.8 Gm.

Triturate the stearic acid with the ammonia water in a mortar to a smooth paste, adding additional ammonia water, if necessary, until a slight excess is present. Mix this pasty mass with 4000 Cc. of distilled water, and heat it until a solution results. Dissolve the zinc sulphate in 2500 Cc. of distilled water, warm both solutions to about 50° C. (122° F.) and then pour the solution of the zinc salt slowly into the solution of ammonium stearate, stirring constantly. Collect the precipitate on a strainer, wash it thoroughly with distilled water and dry it without exposure to dust or heat. Finally pass it through a fine sieve. The yield is about 100 Gm.

As zinc stearate is largely and chiefly used as a dusting powder, care should be taken throughout the process, so that the product is practically sterile. The authors describe a second process, in which monohydrated sodium carbonate and zinc acetate are directed in place of ammonia water and zinc sulphate, but they prefer the one described because the latter are more likely to be found in every stock in sufficient quantities.—Proceed. Penna. Pharm. Assoc., 1909, 340–343.

Zinc Oleate—Modification of Process of Preparation.—In view of the idea that oleate of zinc varies in composition according to the method of preparation, W. B. Cowie prepared a sample from good hard soap and zinc sulphate in strict accordance with the official directions, and another from the same materials and by the same method, except that it was heated sufficiently to melt the oleate, which was well mixed with the hot water and then allowed to cool; this was repeated until it was free from sulphates. Each sample was examined, and the results are:

<table>
<thead>
<tr>
<th></th>
<th>Fatty Acids</th>
<th>Melting-points of Fatty Acids</th>
<th>Zinc</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moisture</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sample 1 (strictly B. P.)</td>
<td>4.3 per cent.</td>
<td>87.5 per cent.</td>
<td>27°–28° C.</td>
</tr>
<tr>
<td>Sample 2 (melted)</td>
<td>3.6 per cent.</td>
<td>86.8 per cent.</td>
<td>26°–27° C.</td>
</tr>
</tbody>
</table>

The results vary but slightly, the one made at the higher temperature containing 0.7 per cent. less fatty acids and 0.1 per cent. less zinc, and for a substance of this nature the difference is negligible. Mr. Cowie therefore recommends the second method when the oleate is to be used solely for ointment, as much time is saved in collecting and drying; but that made by the first method is vastly superior for the powder form, as it is readily friable and easily mixed with other powders.—Chem. & Drugg., Dec. 25, 1909, 968.

Zinc Oleate, B. P.—A Practical Suggestion.—W. B. Cowie has prepared oleate of zinc from good hard soap and zinc sulphate in strict accordance
PULVERES.

with the official directions (B. P.), and another sample from the same material, deviating from the official directions however by heating sufficiently to melt the oleate, which was well mixed with hot water and then allowed to cool, and this repeated until it was free from sulphates. The results of examination of the two samples show them to vary so slightly in their composition, that the difference is negligible. The second method is so much more convenient and expeditious than the official one, that it is recommended by the author when the oleate is to be used solely for ointment; but that made by the official method is vastly superior for the powder form, as it is readily friable and easily mixed with other powders.

Zinc Stearate—Commercial Variation.—Of four samples of zinc stearate examined by C. E. Hoffman, two on ignition left a residue of 15.5 per cent., one 11.4 per cent., and one 9 per cent. The stearic acid liberated from the third sample had a m. p. of 60° C.; that from the fourth sample was yellow and melted at 72° C. A sample made with zinc acetate and soap met the U. S. P. requirements.—Amer. Journ. Pharm., May, 1910, 243.

PULVERES.

Plant Powders—Convenient Method of Determining Mineral Impurities.—Rackwitz directs attention to a convenient method for expeditiously determining sand and other mineral impurities in vegetable powders, which has been in use with advantage in agricultural experiment stations. It depends on the facility with which the vegetable matter, being specifically lighter, will float on the surface of chloroform (or concentrated zinc sulphate solution), while the heavier mineral matter (sand, etc.) rapidly settles to the bottom. The experiment is made by the aid of the "sediment funnel," shown by the accompanying cut (Fig. 60), which consists of a small, pear-shaped vessel with a cup-shaped expansion above, and a narrow, elongated neck beneath, the lower orifice of which is closed by a stopper or by means of a rubber tube and clamp. It is fitted also with a ground-glass stopper (b) with a long stem, which shuts off the neck from the pear-shaped bulb, while the cup-shaped orifice may be closed by the larger, short-stemmed ground-glass stopper (a)—these positions being shown in the drawing. In use, the pear-shaped bulb is filled with chloroform to about half its capacity, a weighed quantity of the powder under examination is introduced and, the stopper (a) being inserted, the contents are mixed and the funnel set aside. In a short time the mineral matter will have completely subsided into the neck; the stopper (a) is removed, the smaller stopper (b) is inserted, and the contents of the narrow neck are allowed to flow into a tared platinum capsule by removing the stopper at the lower extremity or opening the clamp on the rubber tube if such be used. The chloroform is decanted from the sediment so collected, the re-
residual matter is dried, the capsule heated to final redness, and, after cooling, weighed.—Pharm. Ztg., liv (1909), No. 56, 551.

He addressed a number of drug millers for an explanation of this deplorable condition, and among the replies received the following will probably best explain the cause:

"To convert the gum into powdered form requires manipulation consistent with the condition of the gum as we receive it. There are no two cases of gum the same. There is not enough asafetida tears obtainable in
foreign countries or this country to supply one-hundredth part of the demand for powdered asafetida. We mean to explain that the powdering of the tears for commercial demands is out of the question. We separate the hard gum from the soft gum. The hard we powder; the soft we sell in the whole state, but it is very seldom the gum is hard enough to convert into powdered form in its natural condition, and after it is in powdered form it is assayed and we sell it on the assay to the manufacturer, who conducts the manufacture of the article, in keeping with the assay, in preparing a preparation equal to the requirements of the U. S. P."—Proceedings Ohio State Pharm. Assoc., 1909, 50–51.

"Powdered" Castor Oil.—Preparation with Magnesia.—Otto B. May states that by admixture with magneria castor oil may be reduced to a powdery form containing 50 per cent of the oil in an unchanged condition. The powder is stable, odorless, readily taken, and well borne, while its therapeutic efficacy is as great as the same dose of pure castor oil—the magnesia contributing its own properties to the powder. While the use of magnesia as an excipient to convert liquids into dry or semi-dry substances is not new, in all other cases the magnesia combines chemically with the substances with which it is mixed; but in the case of castor oil powder the oil is in no way changed, and on extracting the castor oil with ether in a Soxhlet apparatus from 90 to 98 per cent of the entire fat content may be recovered—the remainder being recovered if the powder is acidified with enough diluted hydrochloric acid and the aqueous mixture is shaken out with ether. The only effect of the magnesia therefore is to form a minute quantity of magnesia soap with the free fatty acids present in the oil, which after this treatment shows an acid value of zero. The method may doubtless be applied to other oils. Pharm. Journ. and Pharmacist, Aug. 28, 1909, 296; from Jour. Soc. Chem. Industry.

Compound Powder of Pepsin—Improved Formula.—George M. Beringer gives reasons which justify his conclusion that this preparation should be retained in the National Formulary, but recommends that the present Latin sub-title, "Pulvis Digestivus," be eliminated. Furthermore, the quantity of pepsin in the present formula is but 15 per cent. of saccharated pepsin, equivalent to but 1.5 per cent. of pepsin U. S. P., a quantity too small to obtain satisfactory digestive activity or possibly to comply with the regulations of the Food and Drugs Act. It is proposed to increase this to 15 per cent. of pepsin so as to maintain its proportion equivalent to the pancreatin directed.

As the compound powder of pepsin is largely dispensed in powders, and so becomes subjected to atmospheric exposure, it is recommended that in this preparation the least hygroscopic form of pepsin be used, and it is proposed that the so-called "insoluble" powdered pepsin, of the official digestive value, be directed in its preparation, thus increasing its permanency and stability.
The text of this modified formula would read:

*Pulvis Pepsini Compositus.* (Compound Powder of Pepsin.)

- Powdered pepsin (so-called "insoluble" variety) .............. 15 Gm.
- Pancreatin ........................................................................ 15 Gm.
- Diastase ............................................................................... 1 Gm.
- Lactic acid ............................................................................ 1 Cc.
- Hydrochloric acid ................................................................. 2 Cc.
- Sugar of milk, a sufficient quantity to obtain 100 Gm. of finished product.

Add the acids gradually to 60 Gm. of sugar of milk and triturate until they are thoroughly mixed. Mix the pepsin, pancreatin and diastase, and incorporate this with the acidified sugar of milk. Weigh, and add sufficient sugar of milk to make the weight 100 Gm. Triturate the mixture thoroughly, and finally rub through a hair sieve and preserve the powder in well-stoppered bottles.—Amer. Journ. Pharm., July, 1909, 331-336.

*Granular Effervescent Potassium Citrate.*—Improved Formula.—Robert C. White suggests an improvement in the formula for effervescent potassium citrate which depends entirely on a change in the acids. He finds that an excellent preparation may be made by reversing the amounts of the acids thus making the formula read:

- Potassium citrate .................................................................. 200 Gm.
- Sodium bicarbonate, dried and powdered .......................... 477 Gm.
- Citric acid, uneffloresced crystals .................................. 252 Gm.
- Tartaric acid, dried and powdered .................................. 162 Gm.

The advantages gained, by using this formula, other than that the salts are readily soluble in water are: (1) the solution of the salt is very pleasant to the taste; (2) the physical appearance is greatly improved, due to the fact that the slightly increased amount of water of crystallization present causes the powder more readily to acquire the proper consistence when subjected to heat; and (3) by quick manipulation an increased amount of carbon dioxide is retained in the finished preparation. Drugg. Circ. Dec., 1909, 621.

**Resinæ.**

*Resin of Podophyllum* is the subject of an interesting paper by Wilbur L. Scoville in which he reviews the investigation concerning the resins obtainable from the American species of podophyllum—*P. peltatum*—and from the Himalayan species *P. emodi*—that have appeared in the literature since Dymock and Hooper (1889) called attention to the latter species as a possible source of resin of podophyllum. The paper appears in the "Proceedings," 1909, 897-901.

*Podophyllum Resin.*—Adulteration with aloes.—Joseph H. Williams has recently examined a sample of podophyllum resin which, although coming
within the limits of the B. P. and B. P. C. tests, was proven to contain 25 per cent. of aloes. A trial sample made by mixing 1 part of powdered socotrine aloes and 3 parts of genuine podophyllum resin corresponded to the sample under examination. Pharm. Journ. and Pharmacist, May 14, 1910, 608.

SAPONES.

Sapo Cresolis, B. P. C.—Modification of Formula.—Accommodating the formula for Sapo Cresolis, B. P. C., to Australian conditions, Professor R. C. Cowley, of the Brisbane College of Pharmacy, proposes the following modification:

Olive oil, by weight .................................................. 20.00
Caustic potash ........................................................ 5.75
Water .................................................................. 5.00
Alcohol (S. V. M.), by weight ............................... 10.00
Cresylic acid, by weight ........................................... 50.00

Dissolve the caustic potash in the water and alcohol, and heat the solution with the olive oil until saponification is complete and a clear liquid is obtained, then add the cresylic acid. The product is a clear saponaceous liquid, quite soluble in water and neutral to phenolphthalein. The cresylic acid should not have been exposed unduly to air, as this not only causes the acid to darken in color, but causes a certain amount of resinification in the climate of Queensland.—Pharm. Journ. and Pharmacist, Aug. 7, 1909, 202.

Liquid Soaps—Formulas.—Dr. Ernst Richter recommends the following formulas for preparing various soap solutions from different oils:

Sapo Liquidus Glycerinatus.—Heat 4.5 Kgm. of olive oil in a capacious enameled dish on a steam bath to 90° C., and 1.65 Kgm. of solution of KOH (47° B.) in a small enameled dish to 80° C., turn off the steam, add 3.85 Kgm. of alcohol to the oil, then the KOH solution, and mix energetically until saponification is completed, which requires about two minutes. The soap so produced is immediately dissolved in a mixture of 1.5 Kgm. glycerin and 12.5 Kgm. distilled water and filtered after cooling. Solution of KOH, of 47° B., prepared by electrolysis on a large scale, is obtainable on the (German) market, and very much cheaper than if prepared from fused KOH.

Spiritus Saponatus e Sinapolo.—This is prepared by saponifying 2250.0 Gm. of fixed oil of mustard with 1875.0 Gm. of alcohol and 825.0 Gm. of solution of KOH (47° B.) in the same way as in the preceding formula, then dissolving the soap produced in 9375.0 Gm. of alcohol and 8175.0 Gm. of distilled water, and filtering after cooling.

Spiritus saponatus kalinus gossypatus is obtained by saponifying 909.0 Gm. of cotton oil with 757.0 Gm. of alcohol and 328.0 Gm. of solution of
KOH (47° B.), as in the previous formulas, dissolving the soap in 1219.0 Gm. of alcohol and 732.0 Gm. of distilled water, filtering after cooling, and perfuming with 55.0 Gm. mixt. oleosa balsamica or any other desirable perfume.—Apoth. Ztg., xxv (1910), No. 20, 168.

Spiritus Saponatus, G.P. IV—Improved Process.—Schnabel recommends the use of freshly prepared and more concentrated solution of alkali for preparing spiritus saponatus, and suggests the following improved formula for admission into the G. P.: Olive oil, 60, and alcohol, 75, are placed in

a flask, and this into warm water or on a hot surface. Potassium hydroxide, 10.5, is dissolved in water, 19.5, and the warm solution is at once added to the oil mixture, which is then shaken until clear, or at intervals while the flask stands in a warm place. Then alcohol, 225, and water, 210, are added, and the mixture, after standing several days, is filtered.

SPIRITUS.

Spirit of Nitrous Ether—Improvised Nitrometer.—John Watson constructs an efficient nitrometer from an ordinary burette, with glass cock, a short length (about 1 foot) of rubber "infant-feeder" tubing, a perforated cork bearing a short piece of glass tubing, the barrel of a one-ounce glass syringe, and a small glass funnel. The apparatus as constructed is shown by the accompanying photograph (Fig. 61), in which the leveling tube (the syringe barrel) is attached to the burette stand by a piece of twisted wire in order that it may be conveniently shown. The burette, with the small funnel attached to the tap end, is inverted and the leveling tube attached to the large opening below by means of the cork and rubber tubing. It is then filled with brine in the usual manner, care being taken to fill it up so that some comes through the tap and fills up any small interstices between the funnel and the pointed end of the burette: The spirit, H₂SO₃ and KI solution are then consecutively added and after the evolution of gas is completed the leveling tube is adjusted to the proper height and the volume of gas read of.—Pharm. Journ. and Pharmacist, March 26, 1910, 389.

Spirit of Nitrous Ether, B. P.—Complex Constitution.—Having occasion to estimate the alcoholic strength of concentrated spirit of nitrous ether (1–7) for excise purposes, and no method being at hand, Harold R. Jensen found it necessary to devise one, which consisted in "salting out" the ether by means of a concentrated solution of calcium chloride (50 Gm. CaCl₂ in 50Cc. water) in the cold, and estimating the alcohol in the saline solution, by dilution and distillation, in the usual manner, after having satisfied himself that no ethyl nitrate was retained by it. In this way he determined an alcoholic strength of 81.6 per cent. An examination of the "salted-out" ester layer, however, revealed the fact that this measured 8 Cc. whereas from the quantity of concentrated spirit taken (25 Cc.) this should have measured only 4.7 Cc. since by the nitrometric test its spirit was shown to contain 20 per cent. of ethyl nitrite. The author suggests that the increased volume of ester may be accounted for by a more complex constitution of the esters produced by the reaction, and that the ethyl nitrite is possibly combined with some other compound. There is some evidence of a CH₃CHO—C₂H₅NO₂ compound, and it is even possible that an ethyl nitrite-alcohol compound exists, analogous to the ethyl acetate-alcohol compound recently indicated by Habermann and Brezina. Pharm. Journ. and Pharmacist, May 14, 1910, 606.

Spiritus Aetheris Nitrosi, B. P.—Experimental Preparation.—Abel Scholar recommends the following details of a method for preparing spirit of nitrous ether in conformity with the B. P. as being particularly suitable as an experiment for students: Place into a 10-oz. bottle 50 Cc. of 90 per cent. alcohol. Add thereto gradually, owing to the rise of temperature,
5 Cc. of sulphuric acid (sp. gr. 1.843). When cool add 50 Cc. more alcohol to which has been added gradually 7.5 Cc. of nitric acid (sp. gr. 1.42), and, lastly, 50 Cc. more alcohol. Lightly cork the bottle and leave overnight. Then distil the liquid, using a saucepan containing warm water, a flask with a side tube containing 5 Gm. of copper turnings, and fitted with a thermometer in the usual way, the flask being attached to an efficient condenser. The 135 Cc. of distillate represents the finished product. The temperature of the flask, with ordinary care, does not rise higher than 77° to 78° C. The action is uniformly moderate, and there is not the least evaporation of the more volatile constituent. The distillate is received in a 200 Cc. graduated cylinder plugged with a ball of cotton.

**Spirit of Nitrous Ether—Deficiencies in Ester Content of Commercial Samples.**—Prof. L. E. Sayre, Director of Drug Analysis, Kansas State Board of Health, says in a recent report that the deficiencies frequently observed in the ester-content of commercial samples of spirit of nitrous ether is evidently due to the neglect of conforming to the directions of the U. S. P. for its proper preservation. It is not infrequently the practice to keep this spirit in half-gallon or gallon bottles, exposed more or less directly to the sun’s rays, whereas if kept in small amber-colored bottles, exposed at most to diffused daylight, comparatively little deterioration occurs. But even here, much depends on certain apparently trivial conditions. Thus, in practice, he has found that if preserved in glass-stoppered bottles, even though these are of amber-glass, the spirit deteriorates much more rapidly than it does in the same bottles if they are stoppered with a good, sound cork. Another practice, which he regards most reprehensible, is that of keeping it in stock in small bottles ready for sale, and particularly such trade packages as are usually supplied to and by grocers. These almost invariably prove perfectly worthless, and should not be permitted on the market.—Pharm. Era, Nov., 11, 1909, 500.

**Spirit of Camphor—Estimation of Camphor by “Salting Out.”**—After reviewing the various methods, official and otherwise, proposed for the estimation of the camphor content of spirit of camphor, Ernst Deussen proposes the following, which he finds free from the faults pointed out to him, and permits the direct weighing of the camphor obtained by a “salting out” process, similar to that used for the estimation of volatile oils in aqueous solutions: Five Gm. of the spirit is weighed into a 50 Cc. Erlenmeyer flask, 20 Gm. of a cold saturated aqueous solution of ammonium sulphate is added and then 30 Gm. of water, rotating the flask. The flask is closed with a cork, shaken to break up the separated camphor, and placed for about twelve hours in a refrigerator. The liquid is then filtered through a smooth filter of 7 Cm. diameter, and the camphor washed with 70 to 90 Gm. of water, so as to collect the camphor at the point of the cone. The wash water is tested for sulphate with barium chloride acidu-
lated with hydrochloric acid, stopping the washing when turbidity appears only after two seconds. The camphor is now pressed on the top with a bent spatula so as to form a cone. The filter is now covered with a watch glass and set aside, while a card, the size of a post card, is weighed together with a suitable watch glass. The camphor is now spread on a porous tile with a nickel spatula in a moderately thin layer. This is allowed to stand for one minute—covered with a watch glass of 10 to 12 Cm. diameter—when it is collected on the tared card, covered with the tared watch glass, and weighed at once. The accuracy of the method is experimentally demonstrated.

The saturated solution of ammonium sulphate is prepared by heating ammonium sulphate in a glass flask in a water-bath for 30 minutes with insufficient distilled water to dissolve the salt after frequent shaking. After cooling and standing 6 to 10 hours the clear solution is decanted, and ready for use. 100 p. of water at 100° C. dissolve 97.5 p. \((\text{NH}_4)_2\text{SO}_4\). Arch. d. Pharm., 247 (1909), No. 4, 307–312.

_Spirit of Camphor._—Use of Oil of Turpentine as a Test.—Meurin proposes to utilize the difference in the solubility of oil of turpentine in alcohol of different strengths for determining the quality of Spirit of Camphor. Pure turpentine oil is soluble in all proportions in absolute alcohol, but proportionally less as the alcohol becomes weaker, so that 100 Gm. of 90 per cent. alcohol will dissolve only 23 Cc. of the oil at 15° C. The solvent action of the alcohol on the oil is, however, increased by the presence of camphor, so that 100 Gm. of 10 per cent Spirit of Camphor prepared with 90 per cent. alcohol will dissolve 33 Cc. of rectified oil of turpentine. To carry out the test, 20 Gm. of Spirit of Camphor are mixed with 6 Cc. of rectified oil of turpentine. If a clear solution results, and the Spirit of Camphor shows the specific gravity 0.845, it is assumed that the Spirit of Camphor has been prepared by the formula of the Pharmacopoeia (Codex). Pharm. Ztg., liv (1909), No. 74, 727; from Rép. de Pharm. 1909.

**SUCCI.**

_Lemon Juice._—Preservation and Storage.—According to the experience of Wilhelm Leske, lemon juice, carefully prepared from sound fruit gathered from November to March, should contain from 6 to 6½ per cent. of acid, keeps well in wood for an entire year, retaining its taste, flavor and color unimpaired if stored in a cool place, and is preserved, either with carbon dioxide under pressure, or by the addition of 0.3 per cent. of formic acid, of 0.05 per cent. of salicylic acid, or of 10 per cent. of alcohol. If the lemon juice is stored in glass and is to be sold and used quickly, formic or salicylic acids may be used as preservatives; but if it is to be kept for a longer time, the kind preserved with alcohol (or alcohol and sugar each 8 per cent.) should be selected. When large quantities
are in question, irrespective of the method of preservation, the juice should invariably be stored in wood, the barrels filled to the bung, and if a portion is withdrawn from the container the empty space should be well sulphured. When bottled for sale, the bottles should be corked air-tight; but by prolonged storage in glass the juice invariably acquires an empyreumatic taste and a darker color.—Pharm. Ztg., lv (1910), No. 19, 191.

**Lime Juice—Test for Sulphurous Acid.**—Having obtained a positive reaction for the presence of sulphurous acid by the official test in lime juice which had been received under a guarantee of purity, Edwin Dowzard examined some lime juice expressed from fresh fruits and obtained the same positive reaction (brown stain on lead paper). Following up his investigation, he finds that this reaction is due to the presence of the small quantity of volatile oil present in the expressed juice, this rendering the official test for sulphurous acid useless in the case of lime juice. Mr. Dowzard finds, moreover, that the expressed juice of fresh lemons acts in a similar manner but not so pronouncedly as pure lime juice. By further experiments he worked out a reliable method which is available both for the qualitative and quantitative estimation of sulphurous acid. The qualitative test, which will detect 1 part of SO₂ in 100,000 parts of lime juice, is carried out as follows: One hundred Cc. of lime juice is acidified with 5 Cc. of 20 per cent. phosphoric acid, and 50 Cc. distilled into 25 Cc. of a 1 per cent. solution of sodium bicarbonate contained in a Fresenius or other absorption flask; the latter is attached to the end of a condenser by a perforated cork. The distillate is placed in a 200 Cc. Erlenmeyer flask, a few pieces of zinc and 8 Cc. of hydrochloric acid added, a plug of cotton wool is inserted in the neck of the flask, and the mouth of the latter capped with lead acetate paper. After 30 minutes the paper is examined, when, if any SO₂ is present, it will be found stained dark brown or black, whereas if the juice is pure the paper remains unaffected.—Amer. Journ. Pharm., Dec., 1909, 561-564.

**Suppositorie.**

**Suppositories—A Simple Suggestion.**—J. Atlee Dean suggests to make suppositories by massing the ingredients in a mortar until plastic, rolling the mass into a cylinder, dividing this into the necessary number of segments and then pressing each segment into the ordinary suppository mold. This suppository combines all the advantages of the hand-made and molded article, and the manipulation is simple and expeditious.—Bull. Pharm., Oct., 1909, 429.

**A Suppository Base,** composed of cacao butter containing 10 per cent. of castor oil and 2½ per cent. of white wax, is recommended by H. A. B. Dunning for summer use, and when a large per cent. of solid extracts are dispensed, in "Proceedings," 1909, 1142-1144.
SYRUPS.

Syrups of the U. S. P. and N. F.—Suggestions of Improvement and Correction of Formulas.—During the past year George M. Beringer and George M. Beringer, Jr., have been engaged upon a series of experiments upon some of the official syrups, and while their work on several is not yet completed, they deemed it advisable to present and record a number of the results obtained. These investigations were undertaken with several points in view: 1. To critically examine the formulas now official and the products of the same. 2. To see if these could not be simplified and improved upon and formulas established by which the pharmacist can prepare all of his syrups in his own store, preferably direct from the drugs, without being dependent on the manufacturer. 3. To determine if the use of fluidextracts in the preparation of syrups cannot be eliminated. 4. To determine the availability of glycerin and water as menstrum for the extraction of the drugs and thus avoid the use of alcohol, the feasibility of which has already in part been demonstrated in the course of experiments upon the fluidglycerates (see "Proceedings," 1908, 981). Referring to the original paper of the authors for the details and results of their investigation, the titles of the preparations considered in their present communication may here find place as follows:

The following improved formulas may serve as examples:

Improved Syrup of Ipecac.—Percolate 70 Gm. of powdered ipecac with a mixture of 100 Cc. of glycerin, 10 Cc. of acetic acid, and 290 Cc. of water, following with water until 600 Cc. of percolate is obtained. In this dissolve 750 Gm. of sugar, and add sufficient water to make the product measure 1000 Cc.

Improved Syrup of Lactucarium.—Beat up 50 Gm. of lactucarium with 400 Gm. of clean sand or 200 Gm. of pumice to coarse powder and place in percolator, shaking down evenly but not packing, pour on sufficient of a mixture of 250 Cc. of glycerin, 100 Cc. of stronger orange flower water, and 300 Cc. of distilled water to saturate and leave a layer above. Then cork up the percolator and cover, and macerate for two days. Then percolate slowly, using the remainder of the mixture and then distilled water until 700 Cc. of percolate is obtained; in this dissolve 600 Gm. of sugar, using a water-bath heat if necessary, and strain, making up the product to 1000 Cc. with distilled water.—Proc. N. J. Pharm. Assoc. 1909, 88–101.
Some U. S. P. Syrups made from Fluidextracts, which in a previous paper (Proceedings 1908, 951) had been reported as being unsatisfactory pharmaceutically, are again referred to in a paper by E. Fullerton Cook, who proposes modifications of the official formulas in accordance with his observations in “Proceedings,” 1909, 1004–1009.

Fruit Syrups—Precautions Identical Whether Made with Preservatives or Without.—W. F. Anderson, representing a large fruit syrup manufacturing firm, says the precautions which are necessary in using fruits and syrups prepared without preservatives are no different than those which should be observed in using goods that contain a preservative. In the first place, it is always better to use a heavy simple syrup in diluting such goods for use. The best simple syrup for this purpose is made by dissolving 14 pounds of pure cane sugar (no blue preferred) in each gallon of water. Heat the water until it boils, then turn off the heat and add the sugar. Boiling the water makes it sterile, and, in turn, sterilizes the sugar if immediately added after removal from the fire. There is no real economy in using less sugar, as is often done, and at most a saving of a few cents per gallon. Scrupulous cleanliness is a sine qua non. They should be well rinsed with hot water each time they are emptied, and only so much of the syrup or fruit mixed at a time as will be rapidly used up. Moreover, when an original container is opened, its contents should be completely used before opening another. Of course, the syrups and fruits should be kept refrigerated as completely as is practicable, and not needlessly exposed. While these precautions may seem a trifle troublesome, in actual practice they will be found no real bother, and they are certainly no more exacting than most of us require in handling fruits in our homes. Mr. Anderson cites the case of a patron who had questioned the practicability of dispensing fruits and syrups prepared without preservatives, and who, after a number of failures apparently confirming his original opinion, had become an ardent convert when the cause of his failure was practically demonstrated by his neglect to observe rules which should have been applied with equal solicitude to the preserved goods formerly used.—Pharm. Era, July 8, 1909, 32–33.

Fruit Syrups—Recommendations for Their Preparation for the Soda Fountain Without Preservatives.—H. E. Barnard, State Food and Drug Commissioner of Indiana, summarizes his conclusions reached after a comprehensive study of the subject of preparing and preserving fruits and fruit syrups for the soda fountain, as follows:

1. Crushed fruits either purchased in glass or tin or prepared by the dispenser after proper formulas will keep without fermentation a sufficient length of time to allow of their disposal.

2. Fruit syrups properly prepared need no preservative other than sugar syrup to hold them until they are used up.

3. The keeping quality of crushed fruits and fruit syrups depends largely upon the strength of sugar solution employed in diluting the concentrates.
4. The heavier the sugar solution the more satisfactory it is. A solution made by dissolving fourteen pounds of sugar in a gallon of water is sufficiently heavy for all practical purposes and in most instances a ten-pound syrup is sufficiently heavy.

5. Goods kept at a temperature not exceeding 55 degrees Fahrenheit will keep indefinitely.

6. Goods when exposed at room temperature during the day and placed in the refrigerator at night will not ferment under seven days, even when made up with a ten-pound sugar solution.

7. Goods kept in jars provided for that purpose in the modern fountain will keep ten days or more without change, even when made up with a ten-pound sugar solution.

8. Crushed fruits and fruit syrups made up by the dispenser will keep in most instances as well as those put up in glass or tin.

_**Dried Fruit Syrups—The Latest Pharmaceutical Novelty.**_—Under the name “Sirupi siccati,” J. D. Riedel, of Berlin, has introduced dried syrups which apparently serve well for the extemporaneous preparation of certain syrups.

_Sirup. Cerasor. siccat. and Sirup. Rubi Id. siccat._ are supplied in form of granular powders of a yellowish to red-brown color, and the taste of pure cherry and raspberry syrups respectively. The powders are soluble in water and form syrups of the typical color of these fruit syrups.—_Pharm. Ztg., lv (1910), No. 14, 147.

_Syrup of Hoarhound—Formula._—Geo. M. Beringer finds that the following formula produces a very stable and satisfactory syrup of hoarhound, for which there appears to be a considerable demand in recent years:

<table>
<thead>
<tr>
<th>Hoarhound in No. 20 powder</th>
<th>200 Gm.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sugar</td>
<td>750 Gm.</td>
</tr>
<tr>
<td>Glycerin</td>
<td>125 Cc.</td>
</tr>
<tr>
<td>Water, a sufficient quantity to make</td>
<td>1000 Cc.</td>
</tr>
</tbody>
</table>

Mix the glycerin with 375 Cc. of water and moisten the drug thoroughly with sufficient of the mixture, then pack lightly in a percolator and add enough menstruum to saturate and leave a layer above the drug and macerate for 24 hours. Then percolate slowly using the balance of the menstruum and then warm water till extracted. Reserve the first 500 Cc. of percolate and evaporate the remainder to 100 Cc. then add the reserve and dissolve the sugar in the liquid using a slight heat if necessary. When cold add sufficient water to make the preparation measure 1000 Cc. and strain. Syrup of hoarhound so made is clear, brown in color and possesses the characteristic bitter and aromatic taste of the drug and after keeping for more than six months has shown not the least tendency to change.—_Proc. N. J. Pharm. Assoc., 1909, 45-46._

_Sirup. Ferri Iodat. Ph. Gallic.—Objection to the Presence of Tartaric Acid._—With the object of preventing the formation of ferrous periodide
and consequent discoloration of syrup of ferrous iodide, the French Pharmacopœia directs the addition of tartaric acid. Queriault however finds, that the presence of tartaric acid is objectionable, since it causes an inversion of the sugar which proceeds quite rapidly.—Pharm. Ztg., lv (1910), No. 51, 107; from Rép. de Pharm. 1910, No. 1.

**Syrup of Iron Iodide.—Expeditious Method of Assay.**—A. Korndorfer recommends the following method for estimating the iodine content of syrup of iodide of iron, which depends on the liberation of the iodine by means of hydrogen dioxide: 5 Gm. of the Syrup, 5 Gm. of water and 3 Gm. commercial hydrogen dioxide are mixed in a glass-stoppered Erlenmeyer flask and allowed to stand 1-2 minutes: then 20 Gm. of chloroform and 10 Gm. of diluted sulphuric acid are added, and the flask is rotated until the liberated iodine is completely dissolved in the chloroform. Potassium permanganate solution (1:1000) is now added, for the purpose of destroying the excess of hydrogen dioxide, until the red color produced slowly fades to a wine yellow, and the mixture is then *rated* with $\frac{8}{10}$ sodium thiosulphate solution, of which 16-16.2 Cc. should be required to completely decolorize the chloroform if the syrup is of official (G. P.) strength. The titration is best made by adding at once 10-12 Cc. of the thiosulphate solution and, after vigorous shaking, carefully continuing the titration, vigorously shaking after each addition until completed. Each cubic centimeter of the thiosulphate U. S. corresponds to 0.0155 ferrous iodide. Expedition is necessary in carrying out the titration because under the influence of the ferric sulphate formed the sodium iodide produced again parts with iodine. Apoth. Ztg., xxiv (1909), No. 90, 850.

**Sirup. Iodo-Tannic, Ph. Gallic—Modification of Process.**—The "Codex" directs that iodo-tannin syrup be prepared by finely pulverizing 2 p. iodine, mixing it with 4 p. tannin and heating it with 360 p. water in a capsule in the water bath at about 60° C.) until the solution ceases to react with starch paste; then to add 640 p. sugar to finish the syrup. Courand, in order to avoid the loss of iodine, suggests that the iodine be triturated with twice its weight of sugar, and that the solution of the iodine and tannin be effected by heating them with the water in a strong, well-stoppered flask, otherwise following the directions of the "Codex" implicitly.—Pharm. Ztg., lv (1910), No. 51, 107; from Rep. de Pharm., 1910, No. 1.

**Compound Syrup of Phosphates, N. F.—A Good Suggestion.**—Andrew C. Parse, discussing the difficulties encountered in the preparation of the compound syrup of phosphates, and particularly the discoloration to which this syrup is subject, attributes the latter to caramelization of the sugar by contact with the strong mineral (phosphoric) acid. He has successfully overcome this trouble by preparing an acid solution, using all the prescribed ingredients except the sugar and coloring matter. Thus, in mak-
ing a quantity sufficient for a quart (32 fluidounces) of finished syrup, the acid solution made strictly according to the formula is brought to the measure of 28 fluidounces with water, filtered, and set aside until wanted. Then, to make an ounce of finished syrup, 2½ drachms of sugar are triturated to fine powder in a mortar, dissolved in 7 drachms of the solution, the coloring matter is added, the mixture is simply shaken, and the syrup, brightly colored, is finished.—Proc. Arkansas Assoc. of Pharm. 1909, 82–85.

Syrupus Rhamni Catharticae, N. F.—Preparation from the Berries.—In their admirable paper on the syrups of the U. S. P. and N. F., quoted in another place, George M. Beringer and George M. Beringer, Jr., bring indisputable testimony that “fermented juice of buckthorn berries,” which is directed in the N. F. for the preparation of the syrup, is not obtainable on the American market and is practically unknown. But both ripe and unripe buckthorn berries are imported from Europe, the latter being used as a dyeing material; and since buckthorn is grown infrequently in the United States, and supplies of fresh berries are therefore not available to the American pharmacists for the preparation of the juice, the authors recommend that syrup of buckthorn be made from the imported berries, which should be mature, ripe and carefully dried. These may be converted into fluidextract (which see under “Fluidextracta”) and the syrup prepared by the addition of 0.2 Cc. each of oil of fennel and oil of cassia to 200 Cc. of this fluidextract and sufficient syrup to make 1000 Cc., or, as the authors prefer, by the following process direct from the berries:

Buckthorn berries, ground. ........................................ 200 Gm.
Sugar. ................................................................. 800 Gm.
Oil of fennel. ........................................................ 0.2 Cc.
Oil of cassia. ......................................................... 0.2 Cc.
Water, a sufficient quantity.

Add the ground buckthorn berries to two liters of boiling water, infuse for two hours, and then express. Infuse the dregs with 500 Cc. of boiling water and express when cold. Mix the expressed liquids, filter, and evaporate to 600 Cc.; in this dissolve the sugar by heat, and when cold strain, add the oils and make up to 1000 Cc. with water.—Amer. Journ. Pharm., July, 1909, 323–326.

Senna Syrups—Efficient Formulas.—Dr. P. E. Homnell, referring particularly to the aromatic and to the compound syrup of senna of the N. F., says it is surprising how many physicians either do not know, or else forget, that there are some palatable and efficient purgative syrups in the N. F. and U. S. P. Both of the N. F. preparations, when properly compounded, will please the prescriber, and possess the distinctive merit of not being imitations of proprietary preparations. The U. S. P. syrup of senna is also a good preparation, but should be free from precipitation and cloudiness,
which is the principal objection to it. The author therefore suggests the following improved formulas for

**Syrupus Sennæ U. S. P.**

- Fluidextract of senna .................................................. 250 Cc.
- C. P. glycerin ............................................................ 125 Cc.
- Spirit of coriander .................................................... 50 Cc.

Simple syrup, sufficient quantity to make 1000 cubic centimeters.

Mix the glycerin with the fluidextract and spirit of coriander and add a sufficient quantity of syrup to make the product measure 1000 cubic centimeters; mix thoroughly. The finished syrup leaves nothing to be desired. The addition of glycerin is doubly advantageous, being a solvent and a good preservative.

Another very efficient syrup, which the author considers a desirable addition either in the U. S. P. or N. F., is the

**Syrupus Sennæ Mannatus**, a formula for which was given in Prof. Oldberg's Unofficial Pharmacopoeia (1881). This formula is given as follows:

- Fennel, bruised, ten grams ........................................... 10
- Coriander, bruised, ten grams ....................................... 10
- Senna, finely cut, one hundred grams .............................. 100
- Manna, one hundred and fifty grams ............................... 150
- Sugar, six hundred grams ............................................ 600
- Boiling water, sufficient ............................................. —

Make one liter of syrup ............................................... 1000

Digest the senna and spices with 500 fluidgrams of boiling water for two hours, strain, adding enough boiling water through the strainer to make the colature measure 500 fluidgrams. Allow it to settle, and then decant the clear liquid, add the sugar, and dissolve by agitation and the aid of gentle heat. Strain, if necessary, and add enough simple syrup to make the final product measure one liter.—Proc. N. J. Pharm. Assoc., 1909, 50–51.

**Syrup of Wild Cherry—Practical Observations.**—At an evening meeting of the North British Branch of the Pharmaceutical Society of Great Britain, two interesting papers on syrup of wild cherry were read and discussed, the one by Dr. R. R. Hallaway, the other by I. C. Umney. Dr. Hallaway's attention was first drawn to this preparation by finding he could not make a syrup which resembled in taste or odor the syrup sent out by some wholesale firms, though he followed the B. P. process exactly, and carefully examined the bark used to see if it corresponded with the B. P. description. The bought syrup varied, but in most cases the syrup was much deeper in color and much stronger and more astringent in taste than the home-made article. The author pointed out that there has been a change of opinion concerning the value of this preparation in America.
Formerly great value was placed upon it in certain kinds of cough, owing to the trace of hydrocyanic acid present, but leading writers on pharmacology now only regard it as a flavoring. After reviewing the literature (particularly the American) on the subject, Dr. Hallaway gives the details of his own work, the greater part of his paper being devoted to experimental details on methods for estimating the hydrocyanic acid in the syrup, for which purpose he finds the method of Fordos and Gellis (Sutton’s "Volumetric Analysis") more satisfactory than the method recommended by Squire and that of the U. S. P.—the method of F. and G. being based on the reaction: \[ \text{HCN} + \text{I}_2 = \text{HI} + \text{CN}_2 \text{(1 Cc. of } \frac{8}{30} \text{ iodine} = 0.00067 \text{ Gm. HCN).} \] The test is applied to the distillate from the syrup. The practical galenical points made in this paper are: (1) The addition of \( \frac{1}{4} \) fl. oz. of glycerin to 9 fl. oz. water to percolate the bark yields a deeper colored and more astringent syrup. (2) The thick bark yields a little darker colored and more astringent syrup than the young bark, but the difference is very slight. (3) The yield of HCN is larger if a larger quantity of water is used for the preliminary maceration than is directed in the B. P. (4) The addition of glycerin to the menstruum (water) increases the yield of hydrocyanic acid. (5) Even the syrup strongest in hydrocyanic acid does not exceed 0.008 per cent. HCN.

Mr. Umney’s paper deals with a dispensing difficulty that occurs with this syrup—viz., precipitation of alkaloids with those syrups which are made with certain samples of bark as met with in commerce possibly not all derived from *Prunus serotina*. He submitted two samples as imported—one a comparatively thin bark, which might be of the younger branches of *Prunus serotina*, the other much thicker, more astringent, and giving an infusion much weaker in hydrocyanic acid. The syrup from the thicker bark is slightly darker in color and less pleasant in taste. The syrup is now largely used for cough-remedies in which the important soothing bodies such as heroin and codeine are contained. With these alkaloids the astringent syrup, and, indeed, most of the syrups of Virginian prune on the market, naturally cause precipitation of the alkaloids. They should be dispensed, therefore, with the greatest caution. The difficulty can be overcome, or to some extent obviated, by the selection of bark containing a minimum of tannin.—Chem. & Drugg. Dec. 25, 1909, 969.

**Tincturæ.**

The Tinctures of the Pharmacopœia are the subject of a critical review as regards quality of ingredient, process of preparation, and results, in a paper contributed by E. Fullerton Cook, which appears in the "Proceedings," 1909, 1000–1004.

Tinctures.—Proper Definition.—"K" criticizes the definition of the G. P. iv: "Tinctures are alcoholic, vinous or aqueous extractions of plant and animal substances," as being incorrect, and advocates a return to the
definitions of former editions, which consisted of the simple statement:
"The Tinctures, in so far as not directed to the contrary, are prepared, etc., etc." He points out that some of the tinctures, so-called, are simply solutions, and others are mixtures. Pharm. Ztg., liv (1909), No. 90, 891.

**Tinctures—Superior Stability and Activity when Prepared from Fresh Plants with Boiling Alcohol.**—In the course of his studies on the glucosidal constituents of plants, which have been quoted in these reports annually for a number of years, Berquelot has demonstrated, not alone that the activity of tinctures prepared from dried vegetable drugs is far inferior to that of tinctures prepared from the fresh plant, but that tinctures from the latter prepared by extraction with boiling alcohol are decidedly more active than such prepared by cold extraction, and excel also in their appearance and stability. This superiority is imparted to the tinctures prepared with boiling alcohol by the destruction of certain enzymes present in the fresh plant which otherwise, even in the tinctures prepared by the older method, continue to exert their hydrolytic, oxidizing or reducing properties. While numerous experiments made by other investigators have confirmed Berquelot’s observations, these have heretofore been confined to a small number of plants. Recently, however, M. Lesueur has completed a comprehensive series of studies on the same subject which must be regarded as a valuable supplement to Berquelot’s investigations and a complete confirmation of his views. Thus, in a paper on cherry-laurel leaves which has recently been published, Lesueur gives the comparative values of four different tinctures prepared from the same leaves, two prepared from the fresh leaves—the one by extraction with hot the other with cold alcohol—and two prepared cold and hot from dried leaves: their comparative activity being determined in accordance with the biochemical method of Berquelot described in 1901, and consisting in the present case in the observation in the polariser of the action of invertin and emulsin on the aqueous extract solutions prepared from the respective tinctures. A surprising result, preliminarily, was that the tincture prepared cold from the dried leaves apparently contained the largest amount of glucosides. A distinctly different result was shown, however, when a more accurate method of determining the activity of the tinctures was applied, consisting in the estimation of the hydrocyanic acid produced by the action of emulsin on the glucosidal constituent. The yield of HCN from the respective tinctures (representing 100 Gm. of fresh leaves) was thus shown to be as follows: From the tincture of fresh leaves prepared by the hot method, 0.1254 Gm.; prepared by the cold method, 0.085 Gm.; while from the tinctures prepared by the hot and cold method from the dried leaves the yields of HCN were successively still smaller.—Pharm. Ztg., liv (1909), No. 64, 623–624; from Jour. de Pharm. et Chim.

**Tincture of Colchicum Corns:**—**Method of Preparation.**—In the course
of studies on the influence of the method of preparation on the composition and stability of tinctures, Lesueur determined that the tincture of colchicum corms prepared by extracting the fresh drug with hot alcohol contains the highest alkaloidal percentage. The tincture prepared in the same way from the dry drug approximated in alkaloidal content to the first, but exceeded that in the tinctures prepared according to the Codex. He, however, ascribes this to the difference in the method of drying the drug from that commonly practiced. The corms were not sliced, but dried whole at a temperature of 30 to 32° C. Pharm. Ztg., lv (1910), No. 28, 282; from Journ. de Pharm. et Chim. 1910, No. 6.

Tincture of Citro-Chloride of Iron, N. F—Advantage Over the U. S. P. Tincture of Ferric Chloride.—E. A. Ruddiman points out some of the advantages of tincture of iron citro-chloride over the U. S. P. tincture of ferric chloride. Apart from the taste, it is much less likely to produce precipitation or coloration in admixtures with other medicaments, and is more quickly made, requiring simple admixture of the ingredients (solution of ferric chloride, solution of sodium citrate and alcohol), without the subsequent prolonged standing required by the U. S. P. tincture. The author mentions some of the incompatibles of both tinctures and shows a favorable balance for the N. F. preparation which, he thinks, should replace the tincture now official in the U. S. P.—Proc. Tenn. Pharm. Assoc., 1909, 50–51.

Tincture of Digitalis—Practical Observations on Preservation and Standardization.—In a paper communicated to the North British Branch of the Pharmaceutical Society of Great Britain, Dr. R. R. Hallaway, after reviewing the work of Dixon and Haynes, of Focke, and of Dr. Houghton, which have pointed out the limitations of the stability of tincture of digitalis leaves, arrives at the conclusion that six months is a safe limit of time to keep this tincture, and that every pharmacist should endeavor to prepare just sufficient tincture to last him for this period or less. Moreover, taking everything into consideration, he thinks that the pharmacists are quite justified in using a shelf-bottle for dispensing stock of digitalis tincture, provided it is kept out of direct sunlight in an amber-colored bottle. As regards the drug itself, he agrees with Mr. Martin that digitalis leaves, properly collected, dried, and stored, retain their activity for many years. Furthermore, there is need (1) for work on the method of extracting the drug, and (2) as to the best method of standardizing. Referring to the verdict of the Committee of Reference on the B. P. that physiological tests are not feasible, he says that this may be so, but there is plainly a demand for drugs tested in this way; but even if not considered suitable to
authorize such tests in the next B. P., could not the monograph on digitalis embody the results on physiological standardization obtained by pharmacologists? They might also give the dispenser clear instruction as to the preservation of the crude drug and its preparations, and also how long these retain their activity.—Chem. & Drugg., Dec. 25, 1909, 970.

Compound Tincture of Gentian—Addition of Glycerin to the Menstruum Suggested as an Improvement.—Bloomfield Hulick observes that while the use of the stronger alcoholic menstruum than diluted alcohol directed in the U. P. P. viii for the preparation of compound tincture of gentian has been some help in preventing precipitation, it does not accomplish all that was expected. Some experiments made by adding glycerin to the menstruum promise better results. A tincture made with 120 Cc. of glycerin to each 1000 Cc. remained clear and showed no disposition to precipitate after standing three months.—Proc. N. J. Pharm. Assoc., 1909, 87–88.

Tincture of Iodine—Character of Changes on Keeping.—C. Courtot has experimentally determined that by prolonged keeping tincture of iodine undergoes changes resulting in the formation of hydriodic acid, acetaldehyde and acetic ether. By the action of the iodine on the alcohol, hydriodic acid and acetaldehyde are primarily formed. The latter, in presence of water, is then by action of iodine, oxidized to acetic acid, an additional quantity of HI being formed. In turn, the acetic acid then reacts with the alcohol to form acetic ether. These reactions are more pronounced during the first few months but gradually decrease, until eventually a condition of equilibrium is reached. In an example, a tincture prepared with 95 per cent. alcohol and 87.63 Gm. of iodine per liter, contained after seven months 15.36 Gm. of HI and only 72.32 Gm. of free iodine.—Pharm. Ztg., lv (1910), No. 346; from Journ. de Pharm. et Chim., 1910, Nos. 6 and 7, 297.

Tincture of Iodine.—Variable Commercial Quality.—Analyses of 7 samples of tincture of iodine by Ernest A. Noedel, obtained in Philadelphia and vicinity showed an iodine content varying from 4.522 to 7.172 Gm. the average being 6.455 Gm. in 100 Cc. The specimen containing the lowest amount of iodine, contained no potassium iodide; the other contained from 4.08 to 5.16 Gm. K. I. in 100 Cc.—average 4.67 Gm. Amer. Journ. Pharm. May, 1910, 243.

Commercial Tinctures of Iodine have been examined by Agnes Dunning and L. E. Sayre who communicate their observation in a paper which appears in the “Proceedings,” 1909, 868–870.

Warburg’s Tincture.—Criticism.—H. C. Bradford criticises the formula for Warburg’s Tincture as it appears in the National Formulary and suggests certain improvements which are best consulted in the original, preferably in connection with the abstracts on similar criticisms which appear

TROCHISCI.

Troches—Official and Non-Official—Improved Formulas.—Geo. M. Beringer, Jr., and H. D. Kresge, regarding troches as the most elegant pharmaceuticals, yet the most neglected by the Pharmacopoeia and National Formulary, have conducted a series of experiments with the object of the betterment of the published formulas. The flavorings of this class of preparations, have not kept pace with improvements in other lines, and it is a noticeable fact, that in all the Pharmacopoeias (U. S., Br. Germ., Swiss, and others) which they have examined, most of the flavorings directed seem to bear no appropriate relation whatever to the substance to be disguised. The U. S. P. also, gives no standard for size or shape, and it may easily be imagined that prescriptions for the same lozenge at different stores will be filled with as many different shaped lozenges. Then also, in conformity with the German, French, Swedish and Swiss pharmacopoeias in which 1 Gm. has been adopted, there should be uniformity in weight. The authors recommend this weight (1 Gm.) in their formulas and that the shape, with the possible exception of troches of cubeb, which by custom are usually dispensed in cylindrical form, should be circular (disc) shaped. The following is a list of troches for which improved or new formulas are suggested, each formula being for 100 troches: Benzoic acid; tannic acid; ammonium chloride; charcoal; compound chloroform; cubeb; gambir; glycyrhiza and opium; guaiac; red gum (eucalyptus gum); krameria; phenol; phenolphthalein; potassium chloride; quinine tannate; santonin; santonin and calomel; sodium bicarbonate; sulphur and potassium bitartrate; elm.—Proc. N. J. Pharm. Assoc. 1909, 80-87.

UNGUENTA.

Ointments—Novel and Expeditious Method of Ascertaining Comparative Melting-Points.—E. Thorp has found the following method to give satisfactory results for ascertaining comparative melting-points of many ointments, which, of course, is not applicable for determining actual melting-points, but may prove useful as a means of classification and as an indication of their strength or sophistication:

Glass tubes of 5 Mm. diameter and 3 Cm. length were selected, and a small quantity of the ointment filled in up to a 1 Cm. mark on each by inserting the tube into the cold ointment under examination.

The outside of the tube being cleaned, 0.5 Gm. mercury was dropped into the open end, the mercury resting on the column of ointment.

The tube was then fastened by an elastic band to the bulb of a sensitive thermometer, and the whole suspended in a flask of cold water over a
small Bunsen-burner flame, and gently heated up. Directly the sample commences to melt, the pressure of mercury forces the ointment out of the lower end of the glass tube, and the temperature is read off.

The following ointments examined by the above simple method yielded temperatures as indicated:

Ung. boric. ..................... 41-42° C. Ung. hyd. ammon. ................ 39-40° C.
Ung. bellad. ..................... 35-36° C. Ung. hyd. ox. rub. ................ 40-41° C.
Ung. cetacei. .................... 40-41° C. Ung. paraffin ................... 40-41° C.
Ung. carbolic ................... 39-40° C. Ung. plumbi acet. ............ 44-45° C.
Ung. canthar. ................... 48-49° C. Ung. resinæ .................... 59-60° C.
Ung. eucalypti ................... 41-42° C. Ung. staphisagri ................ 43-44° C.
Ung. gallic. ...................... 34-35° C. Ung. sulphuris ............... 35-36° C.
Ung. galleae c. opio ........... 35-36° C. Ung. zinci ..................... 35-36° C.

Cerates and Ointments—Suitable Base.—George H. White criticises the various bases that have in the course of time been substituted for wax and lard in the official cerates and ointments. In an experience covering many years he has found the unguentum of the U. S. P., 1890, made with yellow wax and benzoinated lard, to be an almost perfect base, which he believes can be used for all ointments except that of mercuric nitrate. As an alternative he recommends a base composed of 2 parts olive oil and 1 part wax.—Proc. N. J. Pharm. Assoc., 1909, 78-79.

Ointments, Liniments and Plasters—Preparation with Sesame Oil.—G. P. Forrester has compiled the following list of ointments, liniments and plasters of different Pharmacopoeias in which the olive oil has been replaced by sesame oil (which see under “Materia Medica”):

The different formulae given for the preparation of an equivalent of cold-cream and the use of sesame oil in their preparation point to the fact that these have borne the test of practical use. Chem. & Drugg., April 16, 1909, 51.

Ointments and Lard.—Oil of Pimento to Prevent Rancidity.—G. Welborn states that oil of pimento has been found to possess valuable qualities when mixed with melted lard which has been allowed to cool until it assumes a creamy consistence. Sufficient of this oil is to be added to the lard to render its odor just slightly perceptible. In his experience both lard and ointments thus prepared are preserved from rancidity and discoloration after a lapse of two years under the conditions usually prevailing in pharmacies. Pharm. Journ. and Pharmacist, Sept. 25, 1909, 390.

Petrolatum.—Detection of Saponifiable Fats.—A. Ferraro recommends for the detection of saponifiable fats in petrolatum a reagent which is prepared by adding to a saturated aqueous solution of acid fuchsin just sufficient ammonia to discharge the color. Five Gm. of this is mixed in a porcelain capsule with 20 Gm. of the petrolatum to be tested. In the presence of fats, a portion of the ammonia will combine with the fatty acids, and a pink color will be regenerated in the mixture. Yellow petrolatum shows the reaction less distinctly than white, but it is easily seen on washing the mixture with a little alcohol. The solvent, when separated, should show no pink tint. Pharm. Journ. and Pharmacist, Octob. 23, 1909, 507; from L'Union Pharm., 50 (1909), 400.

Petrolatum Spissum.—An Ideal Ointment Base.—Fred W. Ames, Jr. regards petrolatum spissum as being an ideal ointment base chiefly on the
ground, well understood, of its stability under all conditions of temperature or exposure to atmospheric influence, and its uniformity in character and composition. More noteworthy are his concluding remarks, in which he says that his opinion is based upon nearly five year's observation and experience in the tropics, which gave him an unusual opportunity for experiments, noting their effects, etc. In the number of years in the isthmus he served or came in contact with at least 200 physicians, some of them very exacting men, and he thinks petrolatum had an impartial trial. He found Petrolatum Spissum capable of meeting the most exacting requirements, and feels sure of his ground when recommending it as the ideal ointment base to the exclusion of all others. Merck's Rep., May, 1910, 131.

Unguentum Paraffini, B. P.—Improved Formula.—In search of a more satisfactory formula for "Unguentum Paraffini, B. P.,” J. H. Franklin has prepared ointments, adding 5, 10, 15 and 20 per cent. of paraffin, white beeswax, bleached ceresin, or carnauba wax, to white petroleum jelly. According to the results, which are given in detail, it was found that an ideal ointment—white, firm, smooth, plastic and homogeneous—was produced with 15 per cent. of commercial carnauba wax. Unfortunately, carnauba wax is of uncertain composition as supplied by different makers. Satisfactory ointments may, however, be obtained by either of the following formulas: "A.” White petroleum jelly, 85 parts; pure bleached ceresin, 15 parts. "B.” White petroleum jelly, 84 parts; paraffin wax (m. p. 130° F.), 6 parts; pure bleached ceresin, 10 parts.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 313-317.

Ointment of Ammoniated Mercury—Assay.—Finding several methods for the assay of ammoniated mercury ointment unsatisfactory for one and the other reason, John R. Rippetoe worked out a satisfactory method which, briefly stated, consists in dissolving the fat in 2.5 to 3.0 Gm. of the ointment by shaking with 50 Cc. of ether, then shaking the mixture with 10 Cc. of 10 per cent. hydrochloric acid and 10 Cc. water, to dissolve the ammoniated mercury, and separating the acid solution from the ethereal solution, following this by thorough washing out with water. The acid mercurial solution is then treated with H₂S, the precipitated mercuric sulphide is collected on balanced filters or a Gooch crucible and, after washing, dried at 100° C. to constant weight, which multiplied by 1.0837 gives the weight of ammoniated mercury in the sample taken.—Amer. Journ. Pharm., May, 1910, 223.

Unguentum Hydrargyri Cinereum—Method of Preparation in Small Quantities.—Dr. B. Börner recommends the following method for preparing the ointment of mercury of the G. P. in small quantities by the pharmacist, which secures a fresh ointment of proper quality with little trouble, except the occasional shaking required for short periods during several days: Place mercury, 300.0, anhydrous woolfat, 45.0, and castor oil, 45.0,
into a strong bottle of double the capacity of these ingredients; heat the mixture on a steam-bath, then shake vigorously until cool. Repeat this operation the next day—if convenient twice—shaking each time until cool, and continue this treatment from day to day until the mercury appears completely extinguished when examined under a lens. This requires altogether only a few days. The mixture is then incorporated with a previously melted and nearly cold mixture of lard, 310.0, and suet, 200.0. —Apoth. Ztg., xxiv (1909), No. 94, 887.

**Ungt. Hydrarg. jodat. pultiforme.—Preparation.**—Dr. v. Ammon gives specific directions for preparing mercurous iodide in form of a magma containing the salt in an impalpable condition (see *Mercurous Iodide*, under "Inorganic Chemistry"), from which he prepares a 10 per-cent. stock ointment, possessing unlimited stability, and from this by dilution a 1 per-cent. ointment. The magma (13 Gm., composed of 2.5 Gm. HgI and 10.5 Gm. water) is incorporated with 12 Gm. anhydrous woolfat, removing the water that does not combine and replacing it with woolfat—this requiring an additional 5.5 Gm. of the latter. This forms a 10 per-cent. stock ointment from which the 1 per-cent. ointment, recommended in practice, is prepared by dilution, as follows: Stock ointment, 1 Gm.; anhydrous woolfat, 1 Gm.; American vaselin, 8 Gm. To be carefully protected from light.

**Ungt. Hydrarg. bijodat. pultiforme** is prepared in a precisely similar manner from a magma of mercuric iodide, as indicated in the articles on mercuric iodides above referred to.—Pharm. Ztg., lv (1910), No. 19, 191; from Münch Med. Wschr., 1910, No. 91.

**Cremor Mercurialis—Improved Formula and Manipulation.**—Reginald R. Bennett finds the directions in the supplement to the B. P. C. for the preparation of mercurial cream to yield a satisfactory preparation with extreme difficulty and has devised the following formula and manipulation which has proven very satisfactory:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mercuric chloride</td>
<td>13 60</td>
</tr>
<tr>
<td>Hypophosphorous acid</td>
<td>100 00</td>
</tr>
<tr>
<td>Distilled water</td>

<td>10 00</td>
</tr>
<tr>
<td>Almond oil, sterilized,</td>
<td>100 00</td>
</tr>
<tr>
<td>sufficient to produce</td>
<td></td>
</tr>
</tbody>
</table>

Dissolve the mercuric chloride in 300 of boiling distilled water in a lipped beaker, filter if necessary, and cool the solution to 40° C. Add the hypophosphorous acid, stir very cautiously, and keep the mixture at about 40° C. for an hour, by which time the gelatinous white precipitate of mer-
curous chloride which is first formed should be completely reduced to a heavy greyish-black precipitate of finely divided metallic mercury. Pour off the supernatant liquid and wash the mercury by decantation with successive quantities of cold distilled water until the washings are no longer acid and contain no trace of chloride. The precipitated mercury is then transferred to a porcelain basin and washed first with alcohol, 90 per cent., and finally with a little absolute alcohol; the latter should be poured off as completely as possible, and the basin then kept in a warm place until the last of the alcohol has evaporated. The camphor dissolved in 60 of the previously sterilized almond oil, cooled to about 40° C., is next added to the mercury, and the mixture is rubbed to a smooth cream with a sterile pestle; next the melted Japan wax is added, then the creosote, and finally enough sterilized almond oil to make the mixture measure 100.

**Ung. Resorcini Comp.—Improved Manipulation.**—J. G. Roda, discussing the difficulties encountered in the preparation of a satisfactory compound resorcin ointment, observes that the trouble in the official process seems to be that there is too much oil of cade to be added, and that the moisture from the hydrous wool fat is so great that the powders cannot be thoroughly worked up. They simply lump together and slip around under the pestle. The trouble is overcome, and a perfectly smooth ointment results by operating as follows: Rub up the zinc oxide and bismuth subnitrate separately with portions of the lanolin. Melt the paraffin and petrolatum and add the oil of cade (using only six parts instead of twelve). Next add the resorcinoil to the melted paraffin and petrolatum and thoroughly incorporate. Add this mixture to the zinc oxide and bismuth subnitrate in a large mortar and triturate until cool.—Pacific Pharm., Aug., 1909, 106-107.

**Compound Resorcin Ointment** is improved according to J. O. Burge by a modification of the N. F. formula which he proposes in the "Proceedings," 1909, 1160.

**VINA.**

**Wine of Pepsin—Classification.**—Otto Schmatolla reviews the causes of turbidity of pepsin wines and the difficulty of permanent clarification. He attributes this exclusively to the wine, and particularly to the younger wines, which contain pectin substances and other bodies that are responsible for the change, and recommends the removal of these before dissolving the pepsin in the wine, in which event a second filtration will become necessary, or to treat the wine after the pepsin has been dissolved but before the addition of syrup or, better, the necessary quantity of
sugar. It suffices to digest the wine (after maceration with the pepsin and hydrochloric acid for two or three days) with 2 per cent. of skim milk, heating it rapidly to about 50° C. and immediately cooling, then filtering. This filtration is rapid and the wine permanently clear. The syrup or sugar is then added.—Pharm. Ztg., lv (1910), No. 22, 223.

*Detannating Wine* is the subject of a paper in which Wilbur L. Scoville suggests a simple method of accomplishing this. It is printed in the "Proceedings," 1909, 998-1000.

*Beef, Wine and Iron* is the subject of a critical examination, both as to the quality of the ingredients and the formulas, by L. E. Sayre, which is described in a paper published in "Proceedings," 1909, 1140-1142.

**MISCELLANEOUS PREPARATIONS.**

*Absorbent Cotton—Preparation.*—K. Helfritz gives some practical information concerning the technical preparation of absorbent cotton. The fat is first removed by prolonged boiling under pressure with a solution of NaOH or of an alkaline rosin-soda soap, and thorough washing with soft spring water. The cotton is then bleached by immersion in clear solution of chlorinated lime, the latter being removed by one of several methods. One method consists in profuse washing with water, treatment with very diluted hydrochloric acid immersion in a bath of sodium hyposulphite, to remove the liberated chlorine, and addition of stearin soap. This reacts with hydrochloric acid still retained by the cotton, stearic acid being liberated, and this imparts to the absorbent cotton the peculiar "crunching" between the fingers which has in recent years been demanded of a good article. This "crunching" may, however, be removed by treatment with very dilute solution of sodium bicarbonate. If it is desirable to destroy the absorbent property of the cotton, this may be done by rinsing it in a solution of alum. It is a *sine qua non*, however, that to secure a uniformly satisfactory preparation, the thorough and copious washings with water after all of these operations must be rigidly observed.—Pharm. Zentralh., 51 (1910), No. 6, 101-103.

*Formalin-Iodine Catgut.—Preparation and Advantages.*—Dr. J. Steward finds that skeins of ordinary formalin catgut, immersed for ten days in a 1 per cent. aqueous solution of iodine, afford the most satisfactory material for surgical sutures. At the commencement of the operation, one of these skeins is placed in 1:20 carbolic acid solution, which removes excess of iodine, that might possibly cause irritation. Catgut prepared in this manner does not swell inconveniently, nor become too elastic, as raw catgut
sterilized by immersion in alcohol and water does. This formalin-iodine catgut is very strong and resistant, so that too rapid absorption does not occur. It is very smooth, uniform in diameter, and inelastic, therefore easy to manipulate. Owing to its tensile strength and its resistance to absorption, fine sizes can be used. For skin sutures No. 000,000 is employed: this does not become absorbed for eight or ten days if the wound be dry; it therefore lasts long enough to ensure firm union, but does not require removal, and the stitch-holes soon disappear. For intestinal work No. 00 has given satisfaction. For muscles, aponeuroses, and tendons, Nos. 1 and 2 are used. These sizes are not absorbed for quite a month. Catgut thus prepared is preferable to that which has undergone more complicated processes, and the method is one which can be conveniently carried out by the surgeon. The finer sizes are apt to become somewhat brittle if kept for several months in the iodine solution.—Pharm. Journ. and Pharmacist, Oct. 23, 1909, 507; from Brit. Med. Journ. 1909, 2, 932.

**Chilblain Cones—An Australian Formula.**—P. W. Merfield recommends the following formula for “Chilblain Cones,” which, coming from far-away Australia, deserves attention: Camphorated menthol (2 p. menthol to 1 p. camphor), 2 drachms; iodine, 6 grains; tannic acid, 2 drachms; carbolic acid, 18 grains; powdered alum, 2 drachms; cacao butter, 13 drachms; white wax, 4 drachms. Melt the wax and cacao butter; while still warm add the iodine, and then the carbolic acid, the tannic acid and the alum. When nearing the pouring-out point put in the camphorated menthol, and stir well while pouring the mass into 60-grain pessary moulds. Dispense the cones wrapped in foil.—Bull. Pharm., Dec., 1909, 508.

**Corn Cure—A New Formula.**—F. Boettger recommends the following formula for a corn cure which differs from similar formulas in common use by the introduction of some oil of turpentine and a little glacial acetic acid:

<table>
<thead>
<tr>
<th>Ingredient</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Salicylic acid</td>
<td>300 grains</td>
</tr>
<tr>
<td>Extract of cannabis indica</td>
<td>30 grains</td>
</tr>
<tr>
<td>Oil of turpentine</td>
<td>2 1/2 fluidrachms</td>
</tr>
<tr>
<td>Colloision, U. S. P.</td>
<td>5 fluidounces</td>
</tr>
<tr>
<td>Glacial acetic acid</td>
<td>1 fluidrachm</td>
</tr>
</tbody>
</table>

Mix the three first ingredients, add the colloision, and lastly the acetic acid.—Bull. Pharm., July, 1909, 296.

**Commercial Detergents—False Representation.**—H. Droop Richmond finds that commercial detergents consisting of partially dehydrated sodium carbonate or of sesqui-carbonate are now on the market which are claimed to be from four to ten times stronger than, and sold at from three to seven times the price of, “soda crystals.” Analyses show that the percentage of Na₂CO₃ varies from 47.6 to 90.1, and that they are but rarely above twice the strength of soda crystals. The strength of solutions for cleans-
ing dairy utensils is found to be 0.15 per cent. Na₂CO₃, and it is pointed out that the directions given by manufacturers of detergents yield a solution of substantially that strength. Both by analysis and from the statements of the manufacturers, the claims put forward are shown to be unwarranted.—Chem. News, May 13, 1910, 526.

Magma Bismuthi furnished an interesting topic for review and experimentation by Otto Raubenheimer, who describes in great detail the conditions necessary to produce an acceptable preparation and gives a formula in a paper published in “Proceedings,” 1909, 1024–1031.

Potassium Chlorate Tooth Paste—Formula.—Dr. Ernst Richter recommends the following formula for a tooth paste: Potass. chlorate, 1200.0; medicinal soap, 400.0; precip. calcium carbonate, 800.0; glycerin, 1200.0; distilled water, 360.0; oil of peppermint, 320; oil of cloves, 7.0. The soap and potassium chlorate should be in fine powder, and powdered separately. The paste is dispensed in collapsible tubes.—Apoth. Ztg., xxiv (1909), No. 91, 859.

C. NEW REMEDIES

AND TRADE-NAMED PREPARATIONS.

Acid, Arsino-Salicylic has been introduced as a substitute for atoxyl. It occurs in colorless needles, melting at 300° C., and readily soluble in warm water and alcohol, but sparingly soluble in ether.—Pharm. Ztg., lv (1910), No. 44, 449.

Adrenochrom is the name of a sulphur compound of the suprarenal gland which is exploited as an internal remedy for the treatment of skin diseases.—Pharm. Ztg., liv (1909), No. 68, 662.

Afermol is the name given to a dried bloodserum, obtained from horses with great precaution, which is recommended as a dusting powder, either by itself or in admixture with “substitol” (which see) in the proportion of 3:1 or 4:1.—Pharm. Ztg., liv (1909), No. 68, 662.

Agaroma is the name given to purified gelatina japonica (agar-agar), aromatized, to make it more palatable, with a fruit extract absolutely free from acidity.—Pharm. Zentralh., 57 (1910), No. 4, 66.

Agarose is the name given to a Swiss specialty supplied in form of tablets composed of agar-agar and Bulgarian lactoferment, which are recommended in stomach and bowel affections.—Pharm. Ztg., lv (1910), No. 42, 428.

Almatēin is the name of a new astringent antiseptic, a condensation product of formaldehyde and haematoxylin of the formula C₅₈H₇₆O₂₄. It is supplied in form of a fine, brick-red, odorless and tasteless powder, insoluble in cold water, sparingly soluble in boiling water, but readily soluble in alcohol, glycerin and glacial acetic acid. It is recommended as an

Also.—G. Mossler states that aluminum acetotartrate, which is chemically identical with “also,” is made by evaporating together on a water-bath 100 parts of freshly prepared solution of aluminum acetate and 3.5 parts of tartaric acid, stirring the liquid until a pellicle begins to form, when it is spread on glass plates and dried at a temperature not exceeding 30°. It forms colorless or slightly yellowish scales, with a slight odor of acetic acid, and a rather acid and astringent taste. Very soluble in water (1 in 1), but it dissolves slowly; insoluble in alcohol. If ignited the ash shows the reactions of alumina, but a water solution of the substance gives only a slight turbidity with ammonia, which disappears on shaking, the tartaric acid preventing precipitation. If boiled with an equal weight of potassium carbonate and filtered, the cooled filtrate when acidified with acetic acid gives on standing a precipitate of potassium bitartrate.—Pharm. Journ. and Pharmacist, June 15, 1910, 788; from Ztschr. Allgem. Oesterr. Apoth. Ver., March 26, 1910, 129.

Aluminol.—According to G. Mossler, aluminum naphthol disulphonate, which is chemically identical with alumnol, is made by acting on 3-naphthol with sulphuric acid, converting the sulphonic acid so obtained into the barium salt, and decomposing a solution of the latter with a solution of aluminum sulphate; after filtering out barium sulphate the filtrate is evaporated to dryness. It occurs as a colorless or slightly reddish powder, with slightly acid and astringent taste. Very soluble in water (1 in 1), less soluble in alcohol, insoluble in ether and chloroform, soluble in glycerin; the water solution has an acid reaction, and both it and the alcoholic solution have a slight blue fluorescence, which is increased by the addition of alkali. Strong sulphuric acid gives a red or brown-red color with the solid substance; ferric chloride gives a strong blue color with an aqueous solution; ammonia added to an aqueous solution precipitates alumina, and the liquid then has a strong blue fluorescence. The compound should be free from lead, iron, barium, and free naphthol. It contains from 10 to 18 per cent. of water; after removing this by drying the dried substance should leave 10.5 per cent. of ash of Al₂O₃ on igniting until the weight is constant.—Pharm. Journ. and Pharmacist, June 11, 1910, 727; from Ztschr. Allgem. Oesterr. Apoth. Ver., March 26, 1910, 129.

Amenyl is the name given to a specialty recommended in menstrual disturbances, which is a hydrastin derivative designated by its discoverers as “methylhydrastimidichlorhydrate.” It is supplied in form of faint yellow needles (crystallized from absolute alcohol), melting at 227°; and soluble in water. On addition of NH₃, Na₂CO₃ or NaOH to its solution, the free base is precipitated. This, when crystallized from alcohol, forms
yellowish needles, melting at 192°.—Pharm. Ztg., liv (1909), No. 92, 909; from Therap. Monath., 1909, No. 11.

Amidoazotoluol Medicinale “Agfa” is the title given by the manufacturer to the coloring matter purified for medicinal use, and forms the basis of the so-called “scharlach rot” (scarlet-red) and “scharlach-salbe” of commerce. The medicament is supplied in the form of a red-brown crystalline powder, becoming yellow by trituration, and melts at 102° C. It is sparingly soluble in soda solution with yellow color, but forms a red-yellow solution with concentrated sulphuric acid, becoming purpled-red on addition of water.—Pharm. Ztg., liv (1910), No. 12, 121.

Anisotheobromine.—According to G. Mossler, the compound of theobromine-sodium and sodium anisate, chemically identical with anisotheobromine, is prepared by dissolving 45 parts of theobromine in an aqueous solution of the calculated equivalent of caustic soda, and 30 parts of anisic acid in sufficient sodium carbonate solution to neutralize it, then mixing the two liquids and evaporating to dryness. It forms a white, odorless powder, having a saline, bitter taste, soluble with difficulty in cold water or strong alcohol, more soluble in hot water or dilute alcohol, insoluble in ether and chloroform; its solutions are alkaline in reaction.—Pharm. Journ. and Pharmacist, Nov. 28, 1910, 677; from Ztschr. Allgem. Oester. Ap. Versin, April, 1910, 149.

Antileprol is the name given to purified chaulmoogra oil, and is recommended as a specific in lepra.—Pharm. Ztg., lv (1910), No. 43, 436; from Meck’s Annual Rep., April, 1910.

Antimonyl-Anilintartrate (Emétique d’aniline) is the name given to a remedy for trypanosomen (sleeping sickness). It is supplied in form of handsome white crystals, containing 22 per cent. of antimony, which are soluble in 7 p. of water at the ordinary temperature, and are less poisonous than the corresponding potassium salt, tartar emetic.—Pharm. Ztg., liv (1909), No. 93, 919.

Argonin.—According to G. Mossler, silver caseinate, chemically identical with argonin, is obtained by mixing equivalent quantities of solutions of sodium caseinate and silver nitrate, and precipitating the silver compound by adding alcohol. It forms a greyish-white odorless powder, soluble in water up to 10 per cent., the solution having a weak alkaline reaction and an opalescent appearance; it dissolves in alkaline liquids and solutions of albumen. The aqueous solution is not precipitated by sodium chloride, but on adding nitric acid also silver chloride is formed; on adding to a water solution a few drops of alkali and one drop of copper sulphate solution, and warming gently, a violet-red color is produced; if 0.5 Gm. is ignited, and the ash dissolved in nitric acid, the addition of ammonium molybdate should show the presence of phosphate derived from the casein. The compound should contain 4 to 4.3 per cent. of silver.—

**Arsanaemin** is the name given to a arsenic-iron-pepsin saccharate, containing 0.0076 per cent. of arsenic.—Pharm. Ztg., lv (1910), No. 6, 59.

**Arsen-Haematose**, a new arsenic-iron specialty, has been examined in the Pharmacological Institute of Innsbruck, and determined by the analysis to be an arsenic-iron-phosphorus-cinchona wine, containing 0.04 per cent., 0.15 per cent. phosphorus (both in form of glycerophosphates), and 0.0026 per cent. arsenic in form of potassium arsenite, together with 15 per cent. of extractive matter and 0.045 per cent. of cinchona alkaloids. The wine used in this preparation is apparently a Southern sweet wine, free from tannic acid.—Pharm. Ztg., lv (1910), No. 8, 79; from Wien. Klin. Rundsch., 1910, No. 1.

**Arsotropin** (Tabulettæ Iodi cum Arseno et Belladonna), a specialty recommended for painful nervous affections and epileptic conditions, is composed of arsenic iodide and extract of belladonna.—Pharm. Ztg. lv (1910) No. 37, 376; from Wien. Klin. Rundsch., 1910, 257.

**Astrolin** is the name given to a migrain remedy having a definite composition, which has recently been placed on the market by a German manufacturing house. It is in its chemical relations to be regarded as antipyrine methylethylglycolate (or pyrazolen phenyl dimethyllicum methylethylglyclicum), and has the empirical formula C\(_{16}\)H\(_{22}\)O\(_4\)N\(_2\). Astrolin is a colorless, non-hygroscopic, crystalline powder, having a faint odor, and agreeably acidulous tastes, with a slight, transient bitterness. It is very soluble in (1 part or less) water, alcohol, benzol, chloroform, acetic ether and acetone, but requires 75 parts of ether for solution, and is very sparingly soluble in benzin and ligroin.—Pharm. Ztg., lv. (1909) No. 68, 661.

**Asurol** is a new synthetic mercury compound intended for syphilitic treatment, uniting with a high mercury content (43.3 per cent.) readily soluble in water, forming stable solutions which are not reducible by contact with metals, do not precipitate albumen, and applicable by injection without irritant or toxic effect. The new compound is regarded as being the double salt of mercuric salicylate and sodium amidooxyisobuty late, replacing the insoluble mercuric salicylate with the advantage of solubility and the possibility of insuring the activity of mercury in larger proportion.—Pharm. Ztg., liv (1909), No. 100, 988; from Therap. Monatsh., 1909, No. 12.

**Automors** is the name given to a disinfectant which is exploited as being far superior to carbolic acid, and is apparently a cresol preparation containing some free sulphuric acid. It is a dark brown, clear fluid, having tarry, faintly acrid, odor, and miscible with water to form a brownish, milky
fluid of acid reaction. The preparation is recommended chiefly in form of 1 per cent. solution for disinfecting and deodorizing putrescent matter, feces, etc.—Pharm. Ztg., liv (1909) No. 60, 587.

Auxilium Medici is the name given to a preparation of hydrogen dioxide, which is qualified by its exploiters as being "Hydrogen. peroxyd. medicinale stabilitate prominens." It has recently been examined by E. Richter, who finds it to be a 3 per cent. solution of $\text{H}_2\text{O}_2$ containing phosphoric acid, and possessing good stability, but that it has high acidity, and has no special properties that offer advantages over ordinary 3 per cent. solutions of hydrogen dioxide.—Apoth. Ztg., xxv (1910), No. 12, 97.

Bromophor is a specialty containing dibromlarizinolic acid. Applied by penciling to the skin, it produces a thin cuticle containing 25 per cent. of organic bromine. It is recommended in prurico and erysipelas wounds.—Pharm. Zentralh., 51 (1910), No. 16, 324.

Bromovose is the name given to a fluid said to contain an organic compound of bromine and albumen, and to be devoid of alcohol and free hydrobromic acid.—Pharm. Ztg., liv (1909), No. 74, 727.

Brovalan is the name given to an effervescent salt of mentholvalerate and bromide.—Pharm. Zentralh., 50 (1909), No. 43, 869.

Ceromentumum is the name given to a compound of menthol and eucerin (see Proceedings, 1909, 152), which is recommended as an external remedy in pulmonary tuberculosis.—Pharm. Zentralh. 50 (1909), No. 52, 1082.

Cethal is the name given to a specialty recommended for pulmonary affections and is said to consist of cinnamylmethyl and 10 per cent. of thymol. It is used by inhalation, for which a special apparatus is also exploited.—Pharm. Zentralh. 50 (1909), No. 52, 1082.

Chinothein is the name given to a new antipyretic specialty which is said to be composed of molecular quantities of quinine and antipyrine with the addition of 5 per cent. of caffeine.—Pharm. Ztg., liv (1909), No. 77, 758; from Les nouveaux remèdes, 1909, No. 17.

Choleglycerin is a specialty recommended in hepatic and gall-bladder ailments, which is said to contain the pancreatic ferment and pepsin in saturated glycerin solution.—Pharm. Ztg., lv (1910), No. 25, 253.

Coffeinphenazon (Pyrazolonom Phenyldimethyllicum Coffeinocitricum)—Efficient Formula for a Migrain Powder.—Dr. Bulenheim finds that a stable and efficient headache or migraine powder is obtained by the simple admixture of 1 p. anhydrous citric acid, 9 p. caffeine and 90 p. phenozene, all in fine powder. It is important that the citric acid be rendered completely anhydrous over sulphuric acid.—Pharm. Ztg. lv (1910), No. 30, 304.

Comain is the name given to a new iodine preparation, which is said to be prepared under certain provision from solutions of iodoform and
camphor in benne oil. Under various physical influences, the iodine is liberated from the iodoform; the liberated iodine unites partly with the camphor to form camphor mono- and di-iodide, and partly with the unsaturated oleic acids, yielding with these certain addition products under such regulation as to proportions that each cubic centimeter of the "camain" contains one centigram of active iodine compounds.—Pharm. Ztg., liv (1909), No. 92, 909; from Rep. of Proc. Germ. Naturalists and Physicians in Salzburg.

*Convacoota* are aqueous infusions of vegetable substances which are concentrated *in vacuo* to the original weight of the drug extracted, and are recommended by their exploiter as substitutes for the corresponding infusions or decoctions.—Pharm. Ztg., lv (1910), No. 46, 472.

*Cucasa* is the trade name given to a disinfectant and protective preparation for plants, said to be composed of molecular quantities of cupric sulphate, slaked lime and sugar. It is claimed to possess all the bactericidal properties of "Bordeaux Mixture," with the additional advantage of forming clear solutions in all dilutions and remaining clear for a comparatively long time.—Pharm. Ztg., lv (1909), No. 85, 839; from Südd. Apoth. Ztg., 1909, No. 83.

*Cupferron* is the name given to nitrosophenylhydroxylaminammonium, an organic compound which has the property of forming with copper and iron complex insoluble salts, and therefore serves well for the separation of these two metals from nearly all other metals with which they are associated.—Pharm. Ztg., lv (1910), No. 32, 326; from Gehe & Co.'s Spring Report, 1910.

*Cusol* is the name given to a specialty containing copper citrate rendered soluble by the addition of sodium chloride and boro-citrate. It is supplied in form of solutions, ointments and powder, and is exploited as a remedy for skin diseases.—Pharm. Ztg., lv (1910), No. 33, 334; from Wien. klin. Rundsch., 1910, 188.

*Dedasol* is the name of a specialty containing the total active constituents of an equal weight of digitalis leaves, physiologically standardized. It is supplied in form of

*Dedasol Tablets*, each representing 0.1 Gm. of the leaves.—Pharm. Ztg., lv (1910), No. 25, 253.

*Digistrophan* is the name given to tablets containing the active constituents of digitalis leaves and strophanthus seeds, each representing 0.1 Gm. of the first and 0.05 Gm. of the last named. They are said to be obtained by concentrating the necessary quantities of fluidextracts of the two drugs in a vacuum and incorporating the extract with milksugar.—Pharm. Ztg., lv (1910), No. 30, 305; from Therap. d. Gegenw., 1910, No. 4.

*Droserin* is the name given to tablets containing the peptonizing enzyme
and active constituents of the *Droseracea*, assisted with milksugar. These tablets are supplied in two strengths and are recommended for the treatment of whooping cough.—Pharm. Ztg., lv (1910), No. 4, 37.

*Dysphagin* is the name given to a specialty in form of tablets, recommended in angina and throat affections. It is supplied by its exploiters in three numbers, each differing from the other in composition. No. 1 contains cocaine, menthol, anæsthesin, sodium bicarbonate and aromatics. In No. 2 cocaine is omitted, and No. 3 is said to be composed of anæsthesin, citric acid, tannin and polymeric aluminum acetate.—Pharm. Zentralh., 51 (1910), No. 5, 89.

*Eosserin* is the name given to the antitoxin of erysipelas in hogs.—Pharm. Zentralh., 51 (1910), No. 5, 89.

*Epileptin* is the name given to a specialty in form of 1 Gm. tablets, containing borax, zinc oxide, potassium bromide, phenacetin, sodium lactate, pepsin, sodium bromide, ammonium bromide, boric acid, and starch.—Pharm. Zentralh., 51 (1910), No. 22, 473.

*Eumictin* is the name given to a specialty recommended as an antigonorhooicum. It is supplied exclusively in the form of capsules and is said to be composed of santalol, salol and urotropine; but experimental investigation has failed to establish the presence of the last named ingredient.—Pharm. Ztg., lv (1909), No. 100, 988; from Pharm. Weekblad, 1909, 1027.

*Eupraxin* is the name given to a lecithin compound containing aromatic extractive substances and chocolate, which is recommended as a nerve confection.—Pharm. Zentralh. 50 (1909), No. 52, 1082.

*Eurigen* is a preparation containing 6 per cent. of iodine, 10 per cent. of camphor and 2.5 per cent. of menthol, which is recommended for the relief of frost bite.—Pharm. Zentralh., 50 (1909), No. 52, 1082.

*Fenchyval* is the name given to fenchylisovalerianicacid ester, a nearly tasteless fluid with a faint odor reminding of valerian. It has a sp. gr. at 15° C. of 0.945; b. p. below 120° and 125° C., and is recommended in hysteria, vertigo, nervous depression, etc.—Schweiz. Wschr. f. Chem. u. Pharm., xlvii (1910), No. 15, 237.

*Feolathan* is the name given to a ferruginous specialty which is claimed to be chemically a double salt, ferro ammonium lactate, obtained similarly to ferro ammonium sulphate. It is obtained in the form of a dark brown mass, with green fluorescence, containing approximately 7 per cent. of iron, and is supplied in the form of pills, each corresponding to 0.1 Gm. feolathan.—Pharm. Ztg., liv (1909), No. 88, 873.

*Fermatorol*, a Belgian specialty recommended as an antiseptic and prophylactic, has been qualitatively analyzed by Dr. Aufrecht. It is supplied in collapsible tubes in form of a yellowish, fairly homogeneous, cream-like
mass, and is apparently a mixture of chinosol, aluminum acetate, tartaric acid, and boric acid or sodium borate.—Pharm. Ztg., liv (1909), No. 54, 532.

**Ferricodile** is the name of a Parisian specialty supplied in tubes containing 0.005 Gm. ferrum cacodylicum oxydatum in solution, and in form of pills, each containing 0.025 Gm. of this compound.—Pharm. Zentralh., 51 (1910), No. 7, 131.

**Ferrovose** is the name given to a preparation containing a compound of iron and albumen (see Bromovose).—Pharm. Ztg., liv (1909), No. 74, 727.

**Formeallistan** is a specialty composed of formaldehyde and plant mucilage.—Pharm. Ztg., liv (1909), No. 68, 662.

**Formobas** is the name given to a disinfectant solution of formaldehyde and borax in water. Recent investigations of Kutscher show the preparation to contain 33.3 to 38.3 per cent. of formaldehyde and 0.25 to 1.3 per cent. of borax, but that its stability is limited owing to the polymerization of the formaldehyde.—Pharm. Ztg., lv (1910), No. 40, 409.

**Frangol** is the name given to a liquid extract of frangula bark prepared by a special process, which is recommended as a substitute for liquid extract of cascara sagrada. Possessing the same activity, it is claimed to produce painless peristaltic action, and therefore particularly serviceable during confinement.—Pharm. Ztg., liv (1909), No. 85, 839.

**Frigusin**, a remedy recommended for frost-bites, is prepared under a German patent and is stated to contain organic iodine as active ingredient, which, according to its manufacturers, is *dijodlarizolic acid* (C_{29}H_{16} (OH)_{2}I_{2}). Applied to the skin forms an adherent varnish and gives off iodine without irritant action.—Pharm. Ztg., lv (1910), No. 20, 205.

**Fucophyt** is an antifat specialty in the form of tablets, each containing 0.1 Gm. dry extract of bladder-wrack, powdered poke-root, and dried extract of cascara sagrada.—Pharm. Zentralh., 51 (1910), No. 8, 156.

**Fumiform** is the name given to tablets, weighing 2 Gm. each, composed of purified asphalt with small quantities of myrrh and benzine, which are used in apparatus of special construction for fumigations in the treatment of pulmonary tuberculosis. The patient is required to remain in a close apartment filled with the vapor produced for two hours, once or twice daily.—Pharm. Ztg., liv (1909), No. 68, 662.

**Galegol** is a new galactogogue prepared from *Galega officinalis* under special precautions in extraction of the drug and evaporation of the extract, which is finally granulated with milk sugar. It is supplied in the form of small brown granules, which are readily soluble in water, milk, coffee or tea, and have an agreeable taste. A coffeespoonful of the granules contains ½ Gm. of the extract.—Pharm. Ztg., lv (1910), No. 42, 428.
Gelonida is the protected generic name of tablets containing the so-called "trioxymethylen-gelatin" as a base. The latter, as known, is obtained by the action of formaldehyde on gelatin, and in the opinion of the exploiters of these tablets contains so little formaldehyde that it exerts no prohibitive physiological or therapeutic action. These tablets are characterized by disintegrating with extreme rapidity in contact with water and, as determined experimentally, also with fluids having the composition of the juices of the stomach, so that the rapid dissemination of the medicament incorporated with it is assured. The rapid disintegration of these tablets is shown by moistening, for example, one medicated with acetylsalicylic acid with a drop of water. The moistened surface immediately swells tumor-like, and if thrown into water the tablet completely disintegrates into minute particles in from 3 to 5 seconds. Under circumstances the base of the tablet may be partly composed of starch and talc. The tablets may also be made enteric by a coating of insoluble gelatine, which is soluble only when in contact with alkaline fluids, hence do not disintegrate until they reach the intestinal tract.—Pharm. Ztg. lv (1910), No. 4, 37.

Glutubes are capsules prepared from gluten flour in a manner similar to gelatin capsules which they resemble in shape and general appearance. They are distinguished, however, in that they are insoluble in the juices of the stomach, becoming soluble on reaching the intestinal tract.—Pharm. Centralh., 57 (1910), No. 1, 4.

Gynin, a water-soluble antiseptic compound for vaginal treatment is said to be composed of sodium sulphophenate, alum, sodium chloride, tartaric acid, sodium borate, boric acid, and sozoiiodol-sodium.—Pharm. Zentralh., 50 (1909), No. 52, 1082.

Haemaformyl is the name given to a condensation product prepared by a patented method from the coloring matter of hematoxylin and formaldehyde. It is exploited as a new remedial specialty, recommended externally for the treatment of wounds, skin diseases, etc., of man; internally in the intestinal catarrhs and diarrhoeas of domestic animals.—Pharm. Ztg., liv (1909), No. 100, 988.

Hectagyre is the coined name of a compound of mercury with hectine (which see).—Pharm. Ztg., liv (1909), No. 74, 727.

Hectine—A New Ammonium Derivative.—F. Balzer and A. Mouncyrat describe a new arsenium derivative—sodium benzosulpho-p-amino-phenyl arsenate—which they have named "hectine." It crystallizes in long well-formed needles, very soluble in water. The solutions are stable, and may be sterilized without decomposing. Hectine is less toxic than atoxyl. No ill effects have followed a two months' treatment, during which the total amount of the drug administered has amounted to 8 or 10 Gm. Yet hectine is more active in cases of syphilis in relatively smaller doses than
more poisonous arsenical compounds. When 20 Cgm. were administered hypodermically to a healthy subject, arsenic equivalent to 10 Cgm. was eliminated in the urine in the first twenty-four hours, and that equivalent to another 5 Cgm. in the following sixty hours, the rest was more slowly eliminated until the end of twenty-five days, when no more arsenic was found. In therapeutic doses hектine is therefore quickly eliminated. The dose may be as much as $\frac{3}{4}$ to 3 grains for an adult in twenty-four hours for a fortnight; a fortnight is then intermitted without treatment; then hектine is again administered. It is also given by the mouth in doses of $1\frac{1}{2}$ to 3 grains in twenty-four hours.—Pharm. Journ. and Pharmacist, Aug. 7, 1909, 205; from L'Union Pharm. 50, 1909, 308.

Iodarsotropin is a composite trade-name for tablets containing iodine, arsenic and belladonna.—Pharm. Zentralh., 50 (1909), No. 43, 869.

Iod-Neol is the name given to a stable iodine salve which is claimed to possess the advantage over iod-vasogen in containing iodine in a free state. It is brown-black, of a soft, emolient consistence and readily absorbed by the skin. According to Vogtherr it has the following chemical composition: Neutral fat, 9.98 per cent.; medicinal soap, 7.23 per cent.; lanolin, 46.29 per cent.; free iodine, 1.34 per cent.; sodium iodide, 1.55 per cent.; iodine in organic combination, 4.92 per cent.; water, 26.69 per cent.—Pharm. Ztg., liv (1909), No. 57, 558; from D. Med.-Ztg., 1909, No. 55.

Jecovol is the name given to an egg-emulsion of codliver oil, containing 50 per cent. of the oil, together with hypophosphites in a palatable form.—Pharm. Zentralh., 50 (1909), No. 43, 869.

Iodcallistan is a specialty composed of iodine and plant mucilage.—Pharm. Ztg., liv (1909), No. 68, 662.

Kolyhos is the name given to a tooth paste having the following composition: Soap, 33.0; precipitated lime (sic.), 25.0; absolute alcohol, 20.0; glycerin, 15.0; benzoic acid, 3.0; eucalyptus oil, 2.0; peppermint oil, 2.0; saccharin, 0.5; thymol, 0.25. It has been experimentally examined by E. Walter, at the Hygienic Institute of the University of Greifs- Wald, who reports favorably on its disinfectant action on diphtheria bacilli, streptococci and pneumococci, both in the reagent glass and under natural conditions.—Pharm. Ztg., liv (1909), No. 74, 727; from Z. Bl. f. Bakteriol., etc., 57, No. 4.

Kossam is the name given to "tabloids" prepared from the oily seeds of Brucia sumatrana, which, according to Bertrand, contain a glucoside, "kossamin" (see also "Proceedings" 1909, 195). These tabloids are recommended in cases of amebic dysentery.—Pharm. Ztg., lv (1910), No. 46, 472; from Therap. d. Gegenw., 1910, No. 6.

La Giraucorne is the name given by a Berlin manufacturer to a resinous
resorcin ointment, which is recommended in veterinary practice to promote the growth of horns.—Pharm. Ztg., lv (1910), No. 6, 59.

Lecipon is the trade name of a lecithin preparation, supplied in the form of a pleasant-tasting powder, soluble in water and alcohol. It contains 10.5 per cent. of ovolecithin.—Pharm. Zentralh., 50 (1909), No. 49, 1022.

Leurose is a new name for a proprietary meat solution made by Leube-Rosenthal’s method.—Pharm. Ztg., liv (1909), No. 74, 727.

Liquor Paraffini-Kromayer is stated to be a simple mixture of 30 Gm. each of liquid paraffin, xylol and acetone.—Apoth. Ztg., xxiv (1909), No. 100, 942.

Loretin.—G. Mossier states that m-iod-o-oxyquinoline-ana-sulphonic acid, which is chemically identical with loretin, is prepared as follows: a-quinoline-sulphonic acid is fused with alkali and so converted to a-oxyquinoline, which on sulphonation gives a-oxyquinoline-ana-sulphonic acid; this is neutralized with potash and heated with potassium iodide and chlorinate lime, and on then neutralizing with hydrochloric acid the calcium salt of m-iod-o-oxyquinoline-ana-sulphonic acid separates as yellowish-red crystals, from which the free acid is obtained by the further action of hydrochloric acid. It forms a yellow crystalline powder, almost without smell or taste, soluble with difficulty in cold water (1 in 500) more readily in hot (1 in 70), but little soluble in alcohol, nearly insoluble in ether, chloroform, and fixed oils; the watery solution is of a strong yellow color, and acid reaction; it dissolves to a greater extent in aqueous alkalies, forming salts, these solutions being greenish-yellow and slightly fluorescent. It decomposes about 250° to 270° C. with loss of iodine.—Pharm. Journ. and Pharmacist, May 28, 1910, 677; from Ztschr. Allgem. Oesterr. Apoth.-Ver., April 2, 1910, 141.

Mensan is the name given to a hazelnut preparation which is recommended as a haemostatic. It is prepared from hazelnuts deprived of oil, and is supplied in the form of a sweet, alcoholic fluid, representing 125 Gm. of the fruits in a tablespoonful (= 15 Cc.)—Pharm. Ztg., liv (1909) No. 98, 969; from Münch. Med. Wschr., 1909, No. 48.

Muscusan, a non-corrosive bacterial antiseptic, is stated to be “diborzincdiorthooxybenzoate.”—Pharm. Ztg., lv (1910), No. 25, 253.

Neoferrol is the name of a liquid saccharate of iron and manganese containing lecithin.—Pharm. Zentralh., 1910, No. 19, 382.

Neutralon is the name given to aluminum silicate which is recommended in stomach affections on account of its property of combining with large quantities of hydrochloric acid, with formation of aluminum chloride and liberation of silicic acid. It is supplied in form of a solution, strength not stated, which is given in tablespoonful doses three times daily.—Pharm. Zentralh., 50 (1909), No. 49, 1022; from Berl. Klin. Wschr. 1909, 2165.
Neo-Pyrenol is the name of a specialty having marked expectorant properties, in addition to sedative, antirheumatic and antifebrile effects. The expectorant factor consists of thymol which is rendered water-soluble by means of paradioxy-benzol and with which by a special method a certain amount of Siam benzoic acid (? Rep.) is incorporated. The addition of equal parts of sodium benzoate and sodium oxy-benzoate to four parts of the product of reaction constitutes the "neo-pyrenol." The process of rendering the thymol water-soluble is protected by a German patent.—Pharm. Ztg., liv (1909), No. 73, 715; from D. Aerzte Ztg., 1909, No. 17.

Neopyrin is the name given by its exploiters to "valerylamidoantipyrine," which is supplied in form of nearly odorless white crystals, having a bitter (quinine-like) taste. It is neutral in reaction, melts at 203° C., and is difficultly soluble in water, cold or hot. On boiling with alkali and treatment with diluted acids, neopyrin splits into amido antipyrine and valeric acid. It is readily soluble in methyl alcohol, chloroform, and warm 50 per-cent. alcohol. A bromine compound—

Bromovalerylamidoantipyrine is also described. It forms colorless and tasteless shining scales, having a faint bitter taste, and melting with decomposition at 206° C.; is sparingly soluble in water, cold ethyl alcohol, ether or benzol, but more soluble in hot ethyl alcohol; contains 21.85 per cent. of bromine, and forms well-crystallized salts with acids.—Pharm. Ztg., liv (1909), No. 92, 909; from Therap. Monatsh., 1909, No. 11.

Novocol is the name given to the sodium salt of monoguaiacol phosphoric acid. It is readily soluble in water, has an agreeable taste, and is recommended in the first stages of tuberculosis, in chronic bronchitis, in whooping cough, etc.—Pharm. Ztg., lv (1910), No. 21, 213.

Novoiodin is the name given to a new wound-antiseptic, is said to be composed of equal parts of hexamethylenetramin diiodide and t alc. It is supplied in form of a loose, light brown, perfectly odorless powder of impalpably fine and amorphous structure. It is practically insoluble in nearly all solvents, but is easily suspended in olive oil, liquid paraffin, glycerin and colloidion up to 20 per cent., depositing from these suspensions very slowly. Its activity manifests itself in contact with wound secretions or certain chemical agents by splitting up into iodine and formaldehyde (32 per cent. and 20 per cent. respectively). It is decomposed at 100° C., and sterilization cannot therefore be effected above 80° C.—Pharm. Ztg., lv (1910), No. 13, 128; from Zschr. d. Allgem. Oesterr. Apoth.-Ver., 1910, No. 6.

Ossiostose is the trade name for a phosphate of lime milk.—Pharm. Ztg., liv (1909), No. 74, 727.

Ovaradentriferrin is the name given to tablets containing 0.3 Gm. ovaradentriferrin, which are recommended for the treat-
ment of various female diseases in doses of two tablets daily.—Pharm. Zentralh., 50 (1909), No. 49, 1022.

Ozin is the name given to a salt or saline mixture which is recommended for the convenient generation of oxygen in a special apparatus for inhalations. The principal component is said to be sodium perborate (HBO₃•4H₂O₂), containing 13 per cent. of available oxygen, which is liberated by the action of an iodide (NaI or KI).—Pharm. Ztg., lv (1910), No. 40, 409; from Ztschr. d. Allgem. Oesterr. Apoth.-Ver., 1910, No. 19.

Pergenol is the name given to a mixture of sodium perborate and sodium bitartrate in molecular proportions, supplied in the form of a crystalline powder having a faint boric acid reaction. It possesses indefinite stability in the dry state, but when dissolved in water it is split up into hydrogen dioxide, boric acid and neutral sodium tartrate, the last two uniting to form sodium borotartrate. The preparation is also designated as "solid hydrogen peroxide."—Pharm. Ztg., liv (1909), No. 61, 594.

Peristaltin is the name given to a new mild purgative specialty obtained from cascara sagrada, which has so far however been used only in veterinary practice. It is claimed to be a water-soluble glucoside of the composition C₁₉H₁₉O₅, and does not belong to the anthracene group of bodies to which emodin, etc., belong, but is quite distinct from them. It is readily soluble in water and diluted alcohol, sparingly soluble in alcohol, and insoluble in benzol, ether, and petrolatum ether. The aqueous solution reacts faintly acid and reduces Fehlings' solution when heated with it; is not precipitated from its aqueous solution by lead subacetate, and does not produce with Borntrager's test a red, but a colorless or faint straw yellow ammonia solution. Sulphuric acid dissolves it with a brown color.—Pharm. Ztg., lv (1910), No. 6, 59; from Therap. Monatsh., 1910, No. 1.

Phymochrom (Thymochrom) is the name given to an arsenic compound of the "thymus gland," a specialty recommended for internal use in skin diseases.—Pharm. Ztg., liv (1909), No. 68, 662.

Pitral is the name given to the neutral fraction of coniferous wood tar, possessing the medicinal properties of the latter and devoid of unpleasant side effects.—Pharm. Zentralh., 50 (1909), No. 49, 1022; from Dermatol. Zentralbl., Sept., 1909.

Plasmase, a specialty exploited as a tonic in veterinary practice, has been examined by Fromme who finds it to be composed of arsenic in organic combination (probably atoxy), sodium, phosphoric acid, traces of chlorine, cresols, glycerin, water, and undetermined organic substances. Albumen which has been named as a constituent, could not be detected.—Pharm. Ztg., lv (1910), No. 22, 225; from Berl. Thierärztl. Wschr., 1910, No. 10.

Pneumocol is the trade-name given to "Sirupus aromaticus sulfokreosoto guaiacolicus."—Pharm. Ztg., liv (1909), No. 74, 727.
Porcidin is the name given to a new lymph recommended for the treatment of the swine-plague, which is prepared according to directions given by veterinary surgeon Körner.—Pharm. Ztg. iv (1910), No. 36, 368.

Propyron is the trade-name given to sodium thymico-oxybenzoicum.—Pharm. Zentralh. 50 (1909), No. 43, 869.

Puamambra is the name given to a new aphrodisiac specialty which is said to be composed of ambergris, mentholmethyl ester, yohimbin, Muira Puama, and calcium glycerophosphate.—Pharm. Ztg., lv (1910), No. 15, 147; from Münch. Med. Wschr. 1910, No. 7.

Puriodal is the trade name given to a sarsaparilla syrup containing sodium iodide.—Pharm. Ztg., lv (1909), No. 74, 727.

Pyrolin is the name given to a disinfectant which is said to be a basic magnesium salt, obtained by the addition of magnesia to pyroligneous acid. —Pharm. Ztg., lv (1910), No. 33; from Pharm. Post, 1910, 243.

Radiogenol is the name given to an emulsion of an insoluble radium substance which is supplied in the form of ampuls and is recommended for the subcutaneous treatment of tumors, etc.—Pharm. Zentralh., 50 (1909), No. 52, 1082.

Respiratin, a patented Japanese specialty recommended for asthma, has been examined by R. Ishizu, who finds it to consist exclusively of acid potassium guaiacolate in very impure condition. On the other hand, Yakugakwazashi finds that a "Respiratin" occurring on the market is simply a mixture of 1 part of acid potassium guaiacolate with 99 parts of milksugar.—Pharm. Ztg., lv (1910), No. 24, 245; from Journ. Pharm. Soc. Japan, 1910, 73.

Rimosin Salve is the name given to an ointment recommended by its exploiters for the treatment of eczematous affections, which is stated to be composed of boric acid, lead acetate, mercury, zinc oxide, woolfat, simple ointment, vasoliment and benzoin. Its effectiveness is increased by the simultaneous administration of "rimonin tea," the composition of which is not indicated.—Pharm. Ztg., lv (1909), No. 92, 909.

Robylan (lecithin-iron pastilles) is said to contain 10 per cent. lecithalbumen and 6 per cent. organic iron.—Pharm. Ztg., liv (1909), No. 68, 662.

Salossit is the name given to an organic phosphorus compound with calcium and magnesium.—Pharm. Zentralh. 50 (1909), No. 43, 869.

Santyl-Knoll is now supplied in the form of tablets, each containing 0.4 Gm. santyl (see Proceedings 1906, 706) and 0.4 Gm. magnesium carbonate—the addition of the latter giving to the preparation a mild laxative property.—Ph. Ztg., liv (1909), No. 80, 793.

Sarton is the name given to a nutrient specialty for diabetics, prepared from soja beans by a method which eliminates nearly all of the carbohy-
drates and the unpleasant tasting components of the beans. It is supplied both in form of a thick puree (containing 18–19 per cent. of dry substance of which 8–9 per cent. is albumen) and, latterly in the form of a dry powder.—Pharm. Ztg., lv (1910), No. 30, 205; from Therap. der Gegenw., 1910, No. 4.

*Sepdelen Tablets*, recommended for the treatment of chronic ailments, particularly of females, are said to be composed of sodium citrate, 40, sodium tartrate, 30, sodium phosphate, 10, and sodium sulphate, 20 parts. —Pharm. Ztg., lv (1910), No. 40, 409.

*Serasonol*, a specialty exploited as an antisyphilitic remedy is said to be a soluble mercuro-arsenic compound.—Pharm. Ztg., lv (1910), No. 44, 449.

*Solitania* is the name given to a tænifuge, essentially composed of a bitterless extract of pomegranate bark, castor oil, and aromatic saccharated cacao. It is supplied in form of a brown, aromatic, chocolate-like powder, contains no male fern, and is claimed to be an effective tænifuge, free from the toxic and nauseating properties of the ordinary extract of pomegranate bark.—Pharm. Ztg., lv (1910), No. 25, 253.

"*Spritol*" is the name given by its exploiters to a substitute for alcohol which, it is claimed, is an absolutely new chemical compound and while containing neither methyl, amyl or ethyl compound of the familiar group of alcohols, replaces ethyl alcohol for all purposes except for internal consumption. It is described as a colorless, mobile fluid, having a faint but peculiar odor, and burning with a non-luminous flame, leaving no residue. It goes without saying that the method of its production is withheld as inviolate as is the chemical nature of this mysterious compound.—Pharm. Ztg., lv (1909), No. 81, 799.

*Stilligol* is a specialty recommended for gall-stone, which is supplied both in form of an ointment and as a mixture for internal use. The ointment contains oil of lavender and oil of lemon; the mixture is composed of glycerin extractions of rhubarb, cascara sagrada and various inactive drugs.—Pharm. Ztg., lv (1910), No. 22, 225.

*Subacetol* is the name given by its exploiters to a preparation intended for the convenient production of "Burow’s Solution" (Liquor Burowii)—15.0 Gm. corresponding to the dry substance in 500 Gm. of the solution, which is usually prepared with 25 Gm. solution of basic lead acetate, 5.0 Gm. alum. crud. and 500 Gm. distilled water. Subacetol is a dry, whitish powder.—Ztschr. d. Allgem. Oesterr. Apoth. Ver., 1910, No. 10.

*Subcutin* is the name given to the phenolsulphonate of anaesthesin (which see in Proceedings, 1902, 788), which is recommended as a powerful local anaesthetic and disinfectant, practically free from toxic by-effects. It is obtained by the reaction of equivalent quantities of anaesthesin hydrochloride and p-phenolsulphonate of potassium, forming a white, odorless, crystalline powder of the melting point 195° C. It dissolves in cold water to
the amount of 4 per cent., but is completely and readily soluble in alcohol, and to the amount of 10 or 15 per cent. in a mixture of equal parts of glycerin and alcohol—the latter solution being particularly serviceable for penciling tuberculous ulcers.—Pharm. Ztg., liv (1909), No. 81, 797.

Sublimate Ampouls are suggested by Abry in place of the well known sublimate pastilles for making antiseptic solutions, prepared by the following formula: Mercuric chloride, 12.0; sodium chloride, 12.0; copper sulphate, 2.4; hydrochloric acid, 2.4; carmine. q. s.; water, q. s. to make 24 ampoules, each containing 2 Cc. The addition of copper sulphate and hydrochloric acid serves particularly and well as a deodorant for wounds. —Pharm. Ztg., liv (1909), No. 85, 839; from Journ. de Pharm. d'Anvers, 1909, No. 18.

Substitol is the name given to dry fibrin which is obtained from the fresh uncoagulated blood of healthy animals, particularly horses, by a special method and vigorous observance of antiseptic precautions, and without the use of chemical agents. By the method employed, the red corpuscles are removed on the one hand, the serum ("Aftermol," which see) on the other, and the product is reduced to dryness, at a temperature which does not destroy the active ferments, and then powdered. Substitol is free from germs and may be sterilized without decomposition.—Pharm. Ztg., liv (1909), No. 68, 662.

Susol is the name given to a specialty containing iodine in combination with a beech-tar preparation dissolved in oil, which is recommended in veterinary practice as a bactericide.—Pharm. Ztg., liv (1909), No. 74, 727.

Sydrosan is the name given to an Austrian specialty composed of powdered eucalyptus leaves and flowers, washed sulphur, linden charcoal, oil of melissa, oil of eucalyptus globulus and oil of eucalyptus maculatus var. citriodoris.—Pharm. Zentralh., 50 (1909), No. 43, 869.

Tabulettae Arthriticae-Simon, a specialty containing, besides quinic acid and citric acid, 0.001 Gm. colchicine in each tabule.—Pharm. Ztg., liv (1909), No. 68, 662.

Theolactin.—According to G. Mossier, the compound of theobromine-sodium and sodium lactate, chemically identical with theolactin, is obtained on dissolving eighteen parts of theobromine in the equivalent quantity of caustic soda, adding to a solution of 11.2 parts of sodium lactate in water, and evaporating the mixture to dryness. It forms a white, odorless, hygroscopic powder, having a bitter taste; fairly easily soluble in cold water (1 in 16), more easily in hot, soluble with difficulty in alcohol, almost insoluble in ether and chloroform; the watery solution is alkaline in reaction. The compound should be kept in a well-closed bottle, as otherwise the carbon dioxide of the air liberates theobromine, and the solubility is consequently diminished.—Pharm. Journ. and Pharmacist, Nov. 28, 1910, 677; from Ztschr. Allgem. Oesterr. Apoth.-Ver., April, 1910, 150.
Thilaven is the name given to a specialty exploited for the preparation of agreeably odorous sulphur baths and consists, according to Dr. H. Erdmann, of Linallyl acetate thiosonide (obtained by the action of sulphur on lavender oil) and Alkali thiozionate (obtained by the action of sodium sulphide on sulphur) in alcoholic solution.—Pharm. Zentralh., 51 (1910), No. 8, 157.

Tranquillitum is the name of an ointment containing hyoscyamine, aconitine, methol camphor, chloral camphor, and salicyl derivatives.—Pharm. Ztg., liv (1909), No. 74, 727.

Tuberkinin Pills contain old-tuberculin Koch, quinine and cresote carbonate.—Pharm. Zentralh., 50 (1909), No. 43, 869.

Tuberkulosan is the name given to a bacteria preparation recommended as a remedy in the tuberculosis of neat cattle, but which is claimed also to have proven effective in the treatment of tuberculosis in humans.—Pharm. Ztg., liv (1909), No. 92, 909.

Tubertoxy1-Durodenal Capsules contain old-Tuberculin Koch, Atoxyl and creosote carbonate.—Pharm. Ztg. liv (1909), No. 74, 727.

Tyramine is the name given to tablets containing 0.005 Gm. of oxyphenylacethylamine, which are supplied in this convenient form for preparing injections.—Pharm. Ztg., lv (1910), No. 30. 305; from Bull. des Scien. Pharmaco1., 1910, 177.

Vasotonin is a specialty consisting of "yohimbine nitrate-urethan, which is claimed to be a definite compound having the melting point 260°-261°, and readily soluble in water. It is supplied in ampuls containing about 1.2 Cc. of liquid 1 Cc. containing 0.06 Gm. vasotonin, representing 0.01 Gm. yohimbine Schweiz. Wschr. f. Chem. u. Pharm. xlvi11 (1910), No. 21, 330.

Weiss-Neurolin is the name given to tablets containing 2 per cent. Nutrient salts, 3 per cent. Peroxides and 4 per cent. Iron.—Pharm Zentralh., 50 (1909), No. 36, 749.

Xerase is the name given to a new yeast preparation, exploited for the treatment of colpitis and erosions of gonorrhoeic and non-gonorrhoeic character, profusely suppurating wounds, inoperable carci1mona ulcera cruris, etc. It is stated to be composed of chemically pure dried yeast (150), bolus (125), sugar, (20), and nutrient salts (3), and is supplied in bulk (100 Gm. bottles) and in form of elastic capsules (each 3.0 Gm.).—Pharm. Ztg., lv (1910), No. 8, 79.

Zincochinosul is a specialty obtained by saturating oxychinolinsulphonic acid with zinc oxide or zinc carbonate, in form of a bulky yellow powder, nearly insoluble in water. In round numbers it contains 20 per cent. of zinc oxide and 80 per cent. of oxychinolinsulphonic acid.—Pharm. Zentralh., 50 (1909), No. 33, 686.
Zinkopyrine is a double salt composed of 1 mol. zinc chloride and 2 mol. phenylidimethylpyrazolon, and is recommended to replace pure zinc chloride as being less irritant, and consequently less toxic than the latter. Pharm. Ztg., lv (1910), No. 12, 121.

MATERIA MEDICA.

GENERAL SUBJECTS.

The Pharmacognosy of the U. S. P. is the title of an exhaustive and scholarly paper by Henry Kraemer in which he discusses the subject in its application to the U. S. as well as foreign pharmacopoeias and to commercial drugs, with particular reference to the forthcoming revision leading to the U. S. P. IX. He points out that pharmacognosy is a science of fundamental importance to the pharmacist, and that the results of the studies in pharmacognosy are of the greatest value to the physician in assuring him uniform and efficient medicines; that foreign pharmacopoeias, which give more uniform consideration to the various subjects, are as strong in their treatment of pharmacognosy as is that of chemistry and pharmacy; but that the pharmacognosy of the U. S. P. has not been thoroughly revised for a decade or more, and that the existing needs demand that it shall be completely modernized. The work of the next subcommittee on pharmacognosy will therefore be an extensive one, and a wide co-operation is desirable.—Amer. Journ. Pharm. Febr. 1910, 51–61.

Importation of Drugs—Supervision and Inspection.—George W. Hoover, of the U. S. Department of Agriculture, contributed a highly interesting paper at the April meeting of the Philadelphia Branch of the Association, designed to give a general idea of the inspection of imported drugs under the Food and Drugs Act, and to indicate some of the conditions of the enforcement of the law, and the changes and tendencies of conditions up to the present time. There are at present twenty-one working branches of the Bureau of Chemistry distributed throughout the United States. The function of such laboratories is to inspect imported and domestic foods and drug products and to do such work along the lines of investigation as may assist in the enforcement of the Federal Act. Six of these laboratories were in operation prior to the passage of the Act, but were actively engaged only in the inspection of imported food products, drugs not receiving any consideration until the summer of 1907. Since then it is interesting to note the changes which have taken place both as to quality and labeling of various products which are imported into the United States. As regards the crude drugs, with the progress of the work it became noticeable that there was decided improvement in quality, and that many of the old-time violations no longer obtain. In a number of cases it has been represented that it was difficult to control the gathering
or collection of certain commodities because of the character of the labor and nature of the material, but this contention is apparently not well founded, because numerous importations of such goods are being offered which are found satisfactory. While there is no doubt that a certain small per cent. oppose the proper enforcement of the law and apparently do much to defeat its purpose, it is gratifying to know that the vast majority of importers, manufacturers and dealers have co-operated faithfully in its enforcement.—Amer. Journ. Pharm., July, 1909, 336–342.

*Mexican Medicine—Historical Notes.*—J. F. Lewellyn read a very interesting paper at the 1909 meeting of the Missouri Pharmaceutical Association, in which he gave brief notes on a large number of historical facts connected with the native Mexican practice of medicine, which cannot, however, be profitably condensed, and must therefore be consulted in the original paper in Proc. Mo. Pharm. Assoc., 1909, 105–107.

*The Chinese Materia Medica of San Francisco* is the subject of some interesting "notes" by Albert Schneider, which appear in the "Proceedings," 1909, 852–858.

*The Materia Medica of Perak* is the title of a highly interesting contribution by E. M. Holmes, curator of the Museum of the Pharmaceutical Society of Great Britain, and an honorary member of this Association, which is published in the "Proceedings," 1909, 752–765.

*Drugs—Valuation by Bio-Chemical Tests.*—Introducing the subject of his experience in the testing of drugs by bio-chemical methods, Dr. Wm. Martin observes that the question of testing by physiological methods some drugs whose activity cannot at present be appraised by chemical means is one that has engaged the attention of manufacturing pharmacists for some years, and was first applied systematically for commercial purposes by manufacturers in America. Selecting for his topics the value of the application of bio-chemical tests to cannabis indica, ergot, epinephrine, digitalis, squill and strophanthus, he gives details of his experience and the methods which he has found most practicable, showing, for example, that by the aid of physiological methods of testing a fluid-extract of ergot more active than the official preparation can be produced. The valuation of the cardiac tonics, digitalis, squill, and strophanthus—also becomes possible by bio-chemical methods described, such researches affording to pharmacists an inducement to display yet greater care in the selection and storage of his crude drugs, and the making, keeping, and improvement of preparations from them. With regard to the idea, which seems to be gaining ground, that some tests of a bio-chemical nature should be included in the Pharmacopœia, it is Dr. Martin's impression that the time is not yet ripe for the introduction of tests of this kind, unless, indeed, they were made permissive and not mandatory. Nevertheless, if it were decided that the "frog test" was the most generally satisfactory method of estimating the therapeutic activity of the cardiac
Physiological Standardization—Its Value and Limitations.—Dr. Horatio C. Wood, Jr., contributes an interesting paper on physiological standardization, addressed particularly to those weighing the advisability of introducing biological tests into their business and who wish to know the likelihood of the innovations paying, in which he brings forward some facts that may serve as an aid in deciding whether the biological assay is of sufficient value to justify the expense involved. Speaking of its limitations, he considers it absurd to think of controlling the results of a chemical assay by physiological tests. The experienced chemist can obtain accurate results because he knows the common sources of error which are likely to vitiate his conclusions and how to guard against them. In biological assay we know only a few of the possible causes of inaccuracy, and even some of these we cannot exclude; and believing, as he does, that the biological assay is less accurate, more difficult, and often more costly, he cannot see how it can hope to compete with the chemical as a routine means of standardization. But when we recall that there are over a hundred crude vegetable drugs, including some of our most potent poisons, recognized by the Pharmacopoeia, for which we have no official process of assay, it is evident that there is need for a subsidiary method of determining the comparative activity of our materia medica. Some of these will doubtless be provided with chemical assay tests, while others, unsuited for such, should lend themselves comparatively readily to the physiological assay, particularly the more potent ones, such as digitalis, squill, apocynum, aspidium, cannabis indica, ergot, etc., with which substantial progress has been made on biological lines. The author cautions, however, against accepting the claims of manufacturers regarding the physiological standardization of their products without question. Much of this work is probably being done by young men who have not sufficient training in methods of biological assay, and those who have the necessary qualifications and training can hardly be expected to relinquish comfortable occupations in pleasant surroundings and with a fair emolument, for one more or less dependent, in the drug laboratories, unless inducements are offered that are much better than is at present the case. While the number of drugs which require biological assay may seem at first thought too small to justify the outlay necessary to obtain a man competent to do the work, there are so many other ways in which a pharmacologist may make himself valuable, that there is at least a strong possibility of such an expert being a paying in-
vestment. How, in the author's opinion, it may be brought about that pharmacists may share in this work is very lucidly discussed in the concluding remarks of Dr. Wood's admirable paper, which appears in the Amer. Jour. Pharm., March, 1910, 101-112.

The Pharmacological Assay of Heart-Tonics by E. M. Houghton and H. C. Hamilton, is very interesting. This very comprehensive paper contains numerous charts explaining the action of such well-known heart tonics as digitalis, strophanthus, and squill, and the preparations made from them.—Ibid., p. 773-786.

Assayed Products.—The question of how much deviation from legal standards for assayed products should be allowed by Boards of Pharmacy is discussed in a paper printed in the "Proceedings" 1909, 745-746.

Crude Vegetable Drugs—Valuation on the Basis of Extraction.—Dr. Kunze contributes an interesting paper on the examination and valuation of drugs based on the percentage of extract yielded with the solvents directed for the preparation of tinctures, extracts, wines, etc. Using the respective drugs in air-dry condition, he obtained the following percentages of dry extract: Cortex cascara sagrada, 25.8 to 28.5 per cent.; cortex chine (G. P.), 30 per cent.; cortex condurango, 17.5 and 18.3 per cent.; cortex viburni prunifol., 22.8 per cent.; herba thymi, 14.2, 16.7 and 16.8 per cent.; rad. valerianæ, 10.3 per cent.; rhiza hydrastis, 19.5 to 22.3 per cent.; secale cornutum, 15.7 to 18.6 per cent. The author also records the results obtained by the determination of the extract, specific gravity, etc., in a number of fluidextracts and wines. Regarding the assay of cinchona bark, he points out the importance of specifying and following accurately the described process of determining the alkaloid, the same sample of bark giving different results, depending on the method and variation from the same. In the case of ergot, the author considers it important that the cornutine content be determined according to a fixed standard and reliable method.—Pharm. Ztg., iv (1910), No. 16,158.

Referring to Dr. Kunze's observations on the valuation of crude vegetable drugs and their preparations, L. Derlin questions the reliability of a valuation on the basis of the dry extract. Not only that the drug itself varies in the amount of extractive in different samples, but the preparations themselves will show variations due to the formation of deposits on keeping. Taking hydrastis, for example, he has found in 13 of his own preparations variations up to 16 per cent. Further, to ascertain the depreciation, if any, in extractive, he set aside three fluidextracts under identical conditions and examined them after 6 and 12 months, when they showed the following reductions in extract:

No. 1 from 18.58 per cent. to 17.85 per cent. ............ 4.5 per cent.
No. 2 from 21.88 per cent. to 18.2 per cent. .......... = 17 per cent.
No. 3 from 24.4 per cent. to 21.1 per cent. .......... = 13.5 per cent.

The author also calls attention to the fact that the alkaloidal content
ADULTERATED DRUGS.

149

does not necessarily correspond to the amount of extract, and he demonstrates this experimentally.—Pharm. Ztg., lv (1910), No. 24, 244.

Drugs—Moisture and Ash.—The importance of moisture and ash determinations in vegetable drugs is gaining ground from year to year with the issue of new pharmacopoeias, W. Peters has made and reports a number of such determinations in the hope that his results may give the incentive for similar determinations by other experimenters. Selecting drugs of assured quality and identity, the moisture was determined in average samples by drying to constant weight, followed by the determination of ash, the ash content of the air-dry drug being then ascertained by calculation. The ash determination was made with 1–2 Gm. of the powdered drug carefully prepared so as to represent the entire drug. This was slowly reduced to ash in an open platinum crucible, heated in a slanting position by means of a small flame, frequently stirring with a platinum wire until the reduction was completed, and carefully avoiding a temperature sufficiently high to melt the ash, which might prevent complete incineration by inclosing unconsumed particles of carbon. The results are given in the form of a table, describing the condition of the drug (whole, coarse or fine powder), the amount of moisture, the ash calculated on the air-dried drug, the ash actually found in the dry drug, and the color of the ash. The drugs so examined were the following: Bulbus Scillae, Cantharides, Cort. Chineae Succirubra, Cort. Granati, Flor. Cineae, Fol. Bella

Purity of Some Official and Non-Official Drugs and Chemicals is the subject of a lengthy paper by A. R. L. Dohme and H. Engelhardt, which appears in the "Proceedings" of 1909 (p. 713–719) in which reference is made to a large number of drugs on the market which fail to respond to the official requirements or do not respond to proper commercial standards.

Adulterated Drugs—Frequent Occurrence on the American Market.—L. Rosenthaler, reviewing the recent paper of Dr. H. H. Rusby "On the Crude and Powdered Drugs at the Port of New York during the year 1907–1908" (see Proceedings 1908, 783), observes that it is remarkable that under the stringent customs regulations prevailing in the United States it should become possible for such grossly adulterated drugs from abroad, as are mentioned by Dr. Rusby, to make their appearance so frequently on the open market. Adulterated drugs are rarely offered on the German market, this immunity being doubtless due to the conscientiousness of the jobbing trade. At the same time, the author recommends as the surest safeguard against inferiorities and adulterations, the scrupulous examination of the drugs by the pharmacists themselves, and the
peremptory rejection by them of all drugs that fail to reach the accepted standard of purity and quality.—Pharm. Ztg., liv (1909), No. 61, 594.

Spices and Aromatic Drugs—Determination of Volatile Oil and Moisture.—R. A. Cripps and J. A. Brown describe a method for the determination of moisture in spices and aromatic drugs which is based upon the action of aqueous vapor upon calcium carbide, and measuring the acetylene produced. Half a gramme of the spice or drug, in fine powder, is introduced into a stout tube, 5 in. long and 5/8 in. internal diameter; dried sand is then added to a depth of about 3/4 in., and then calcium carbide, in moderately large pieces, to within 1 1/2 in. of the mouth of the tube, which is connected with a CaCl₂ tube, and this with a nitrometer filled with brine. The tube containing the spice is immersed in a brine bath to the upper level of the carbide, and after the apparatus has been adjusted at atmospheric pressure, heat is gradually applied to the bath, which is finally boiled until the volume of gas in the nitrometer ceases to increase during five minutes. The bath is then removed, and the apparatus allowed to cool. The number of Cc. of gas, after correction for pressure and temperature, multiplied by 0.001725, gives the weight of water in the quantity of spice taken. Total volatile matter is determined by heating the spice contained in a tube in an air-bath at 135°C., whilst a current of dry air is aspirated. Volatile matter is removed thus in an hour or less. The difference between the moisture and the total volatile matter gives the figure for the essential oil. The method is considered by the authors to be extremely well suited for gum-resins, oleoresins, and balsams.—Pharm. Journ. and Pharmacist, Jan. 8, 1910, 27; from Analyst, Dec. 1909, 519.

Ground Spices — Method of Sampling for Examinations.—Harry E. Sindall gives some specific directions for sampling the different spices, a subject of considerable interest to the food chemist. It is well known that the spices as imported contain considerable foreign matter, mostly pebbles and sand, the removal of which is difficult to the miller. Another point to bear in mind is that some spices after being ground have a tendency to separate in layers, depending upon the differences in specific gravity of the particles. How to obtain fair samples of such spices as pepper, cinnamon, ginger, capsicum, is described in some detail in the author's paper, which may be consulted in the Amer. Journ. Phar., Febr., 1910, 80–82.

Botanical Nomenclature.—In the "Proceedings" of 1909 (pp. 673–677) an interesting paper by H. H. Rusby, M. D., on the "Rules of Botanical Nomenclature," in which he advocates its simplification and avoidance of a duplication of terms applied to different plants, and suggests certain safeguards to avoid misunderstanding.

The Botanical Nomenclature of the U. S. P.—Miss Alice Henkel, a worker in the Bureau of Plant Industry, contributes a paper upon the
subject of some desirable changes in the botanical nomenclature of the Pharmacopoeia, which appears in the "Proceedings," 1909, 766-768.

Botany in the Colleges of Pharmacy.—In the "Proceedings" of 1909 (pp. 677-682) appears a paper by Albert Schneider, in which he lucidly presents his views on teaching botany in the colleges of pharmacy, which elicited an animated discussion, participated in by Messrs. Searby, Remington, Whelpley, Wilbert, Kebler and others (see pp. 682-686).

Drug Culture.—At the Los Angeles meeting of the Association a number of papers dealing with the cultivation of drugs were presented and discussed. These, as they appear in the "Proceedings," 1909, are here briefly mentioned by their titles and authority, and constitute a symposium on a subject which, in consideration of the increasing demand and correspondingly increasing scarcity, has awakened wide interest. The page numbers follow the titles of these papers for convenient reference:

*Drug Plants: Breeding.—Rodney H. True, p. 827-830.*

*Belladonna: Culture in the United States.—Albert Schneider, p. 833-843 and p. 1167-1169.*

Medicinal Plants of North America—Botanical and Morphological Description.—Theo. Holm continues his botanical and morphological description of North American medicinal plants, annually contributed since 1907. The following papers, accompanied by excellent illustrations have appeared in Merck's Report during the year covered by this report:

*Euonymus Americanus, L., and E. Atropurpureus, Jacq.—(Both known under the name of "Wahoo," the first also commonly named "Strawberry Bush," while the second, which is official in the U. S. P., is also popularly known as "Burning Bush"), appears in the July number, 1909, 169-171.*

*Liriodendron Tulipifera, L.—(Two varieties are known and distinguished by the color of the wood, the one as "White Poplar," the other as "Yellow Poplar"), in the August number, 1909, 199-201.*

*Diospyros Virginiana, L.—(Persimmon, Date Plum, Yellow Plum, Winter Plum, Guaiacan, Seeded Plum, Pishmin, etc.), in the September number, 1909, 229-231.*

*Sambucus Canadensis, L.—(Common Elder), in the October number, 1909, 259-262.*

*Prunus Serotina, Ehrh.—(P. Virginiana, Mill., not Linnaeus, commonly known as Wild Cherry, Black-, Rum-, Whisky- or Cabinet-Cherry, etc.), in the November number, 1909, 287-290.*

*Corpus Florida, L.—(Dogwood, Flowering Dogwood, Common Dogwood, Boxtree, Florida Cornel, Monhacaniminschi), in the December number, 1909, 318-321.*

*Quercus Alba, L.—(White Oak), in the January number, 1910, 2-4.*

*Aletis Farinosa, L.—(Star grass, Colic-root, Mealy Starwort, Blazing

*Agropyrum Repens,* (L.) Beauv. (couch-grass, quick-grass, quitch, dog-grass. Scotch-grass, witch-grass, quickens), in the March number, 1910, 55-68.

*Rhus Toxicodendron,* L. (poison ivy, poison oak), in the April number, 1910, 95-98.

*Convallaria Majalis,* L. (lily of the valley), in the June number, 1910, 100-162.

**Dosage of Drugs—Inaccurate Estimation.**—It is the usual custom in pharmacological work to state the dosage of drugs as so much per kilogram of body-weight of animal or man. Prof. Benj. Moore, however, points out that this method of stating dosage is inaccurate, the dose of a drug for two individuals of different size, apart from peculiar iodosyncrasies, being proportional, not to their weights, but to their body surfaces, in other words, to the two-thirds powers of their weights. Thus an adult of 150 lb. weight cannot be given fifteen times the dose for an infant of 10 lb., but much more nearly a dose only six times as much. It may be that it is this principle which limits the value of some drugs. Thus atoxyl will cure trypanosome infections in mice and rats, but in cattle, horses, and man, it is much less effectual. A rat of 140 Gm. weight can be safely given 0.02 Gm. of atoxyl. If the dose were proportionate to the body-weight, a man ought to be able to tolerate 10 Gm., but, as a matter of fact, about 1 Gm. is the maximum safe dose, which is in close correspondence to the two-thirds powers of the ratio of weights.—Pharm. Journ. and Pharmacist, Sept. 11, 1909, 342; from Biochem. Journ., iv, Nos. 5, 6 and 7, July, 1909.

**Maximum Doses—Dispensing Difficulties: When these are Exceeded.**—G. P. Forrester observes that the dispenser's attitude towards prescriptions calling for abnormal doses of potent drugs has recently been discussed in Great Britain, but none of those who have taken part in the consideration sufficiently noted the fact that other countries have foreseen the possibility of such occurrences and have established various regulations, usually embodied in the Pharmacopoeia of the country, which place the pharmacist in a position to deal on a legal basis with such cases. Reference to the regulations of this kind in various countries shows how this dilemma is obviated, and the author explains how this becomes practicable by a brief review of the provisions of the Belgian, French, German, Swiss, Italian and Japanese Pharmacopoeias. In this connection the author has appended a few of the maximum doses taken from the various Pharmacopoeias mentioned, including the British. The first amount in each column is the maximum single dose, the second applies to the total amount permissible within twenty-four hours. All weights in grams:

A comparison of the amounts regarded by the above nations as being the highest safe doses to administer shows that there is a considerable degree of unanimity on this point—Italy, as regards caffeine, and Switzerland, in the case of cocaine hydrochl., being the most notable exceptions.—Chem. & Drugg., August 21, 1909, 346.
Irish Moss—Gathering and Preparing for the Market on the Irish Coast.—Samuel S. Knabenschue, U. S. Consul at Belfast, gives some information from personal observation of the collection and curing of "Irish moss" (Chondrus crispus) on the Irish coast. He says it is found in abundance on the Atlantic coast of Ireland and on the shores of Brittany, in France. It grows on rocks in the sea, just below low water mark. It is gathered by the peasants and spread in the sun to dry, after being washed in fresh water. When fresh it varies in color from green to dark purplish brown. The peasants bleach it to an extent by exposure to the sun and by watering, after which it is allowed to dry thoroughly, and is ready for the market. It then is of a light grayish yellow hue. It is stated that the moss may be bleached artificially by the use of permanganate of potash, but no one here knows any details of that process, nor is any moss in the Belfast market bleached otherwise than by sun and moisture, as described.—Amer. Drugg., July 12, 1909, 10.

Fungi.

Yeast—Presence of a Volatile Bactericidal Toxin.—According to A. Fernbach, ordinary yeast when macerated with 1 per mille hydrochloric acid yields an extract which has a marked antiseptic action on fresh yeast cultures. The extracted toxin is an extremely active bactericide towards B. coli communis and Staphylococcus aureus. It is destroyed by heating to 100° C., and traverses a porcelain filter. It is volatile in steam, under reduced pressure at 40° C. The distillate thus obtained is actively bactericidal, and gives no reaction for aldehydes; the residue is not active. The volatile toxin may be obtained direct from fresh yeast.—Pharm. Journ. and Pharmacist, October 23, 1909, 507; from Compt. rend., 159 (1900), 437.

Bèbèes or California "Bees"—What are They?—Lyman F. Kebler directs attention to a peculiar product capable of quickly inciting fermentation in saccharine solutions, which is variously known by the name "bèbèes," "California bees," and "babies." This product, which by some is supposed to be a cereal, looks something like boiled rice, and in water, assisted by a little New Orleans molasses, ferments very rapidly, producing a pleasant liquid to drink, which is reputed to be very effective as a cure in rheumatism. Dr. Kebler became interested in this product some twelve years ago, when its use for the purpose of preparing "bèbèe wine" was quite common. Microscopic examination showed that "bees" or "bèbèes" consisted of aggregations of some form of yeast cells. The size of the various masses varied from that of a small pea to that of a filbert. When introduced into a vessel of water containing a bottom layer of molasses some of the "bees" at first lay dormant on the surface of the
molasses, while others are rising and sinking and a few float on or near the surface of the water. A unique activity is thus developed in this apparently lifeless matter, which is plainly due to chemical (fermentation) action, carbon dioxide and alcohol being formed. The resultant product of fermentation as supplied by a number of druggists at the period mentioned possessed a pleasant champagne-like taste, resembling certain French wines, and was found to contain from 4 to 6 per cent., or more, of alcohol. Dr. Kebler has recently endeavored to obtain some of this peculiar product, but failed, and it is evidently not now on the market. The question as to its origin, which has recently been frequently made to him, cannot therefore be answered until further information is available, the purpose of the present paper being to invite communications on the subject by persons having such additional information.—Pharm. Era, Dec. 16, 1909, 623.

"California Bees"—Probable Identity with "Japanese Beer Seeds."—Referring to Dr. Kebler's paper and inquiry concerning the origin and source of the so-called "California Bees," Prof. John Uri Lloyd observes that he has for many years been searching for a material, which within his knowledge, was used in Kentucky as far back as 1859 under the name of "Japanese Beer Seeds" for making a "home drink." These so-called "beer seeds" emanated from an Eastern establishment, as near as he can remember, and came dried, apparently much like some forms of tapioca, or disintegrated, dried pulp of rice, of a white color, and possessing essentially the fermentative properties of the article described by Dr. Kebler. Professor Lloyd evidently has no doubt of the identity of the two substances, the difference being only in name. As to the origin of this ferment, he gives it as his opinion that it must be looked for in the Orient, and that the original name, "Japanese Beer Seeds," will be found to correctly apply. That it is a ferment in the nature of yeast, he regards as evident.—Ibid., Febr., 1910, 123.

Ergot—Active Constituents to Date.—Prof. Wolfgang Heubner contributes an interesting enumeration of the constituents of ergot which have been isolated to the present day, with particular consideration of their pharmacological activity. Not less than three active constituents, exerting pronounced influence on the muscular system, have been isolated from ergot in a pure condition. Beside these there are a number of substances having the opposite effect, such as ergotinic acid (= secale-amidosulfonic acid) and probably some ammonium bases of the choline-type. Of inactive constituents, "clavine" (composed according to the most recent investigations of leucine, isoleucine and valine) and ergotinine are the most noteworthy; and particularly the last named, which approximates to the active constituents of ergot, and is distinguished only by a minus of H₂O from ergotoxine, were recognized as being the characteristic
toxic constituent of the fungus. *Ergotoxine* itself is amorphous, but yields several crystallizable salts, such as sulphate and phosphate, which are applicable for hypodermic injections. More recently, Barger and Dale have added to this list of active constituents, two others, having a pharmacologic activity resembling that of ergotoxine, but distinguished from this by their solubility and by being easily absorbed. These are respectively *isoamylamine* and *p-oxyphenylamine*—the latter, together with ergotoxine, determining the activity of ergot and its preparations, as well as the toxicity of the other constituents hitherto described as active. These must be regarded as impure products containing some of the true active constituents—usually ergotoxine—in admixture.—Pharm. Ztg., lv (1910), No. 4, 37; from Therap. Monatsh., 1909, No. 12.

**Ergot—p-Hydroxyphenylethylamine One of the Active Constituents.**—Dr. G. Barger's experiments demonstrated to his satisfaction that besides the alkaloid *ergotoxine*, which is only present in very small quantities, ergot contains a second active principle, which proves to be identical with *p-hydroxyphenylethylamine*, recently isolated by him in conjunction with Walpole, from putrid meat. The author expresses the opinion that this body is the chief active constituent of aqueous extracts of ergot, and mentions that its physical constants and physiological properties are identical with those of the body obtained from putrid meat. It is undecided, however, whether this base occurs as such in the ergot, or is formed by bacterial action during the process of extraction.—Trans. Brit. Pharm. Conf. (Yearbook of Pharm.), 1909, 333–335.

**Ergot—A Third Active Principle.**—In addition to the active principles of ergot, "ergotoxine" and "p-hydroxyphenylethylamine" previously described by G. Barger, that author and H. H. Dale find that the drug contains a third active principle which is responsible for the intense activity exhibited by some ergot extracts in producing contraction of the isolated non-pregnant uterus of the cat. This action was found (by Kehrer) to be especially characteristic of Wernich's "Ergotinum Dialysatum." The relative abundance of this principle in dialyzed extracts suggested that it was wholly or partly produced by micro-organisms, and this supposition was confirmed by physiological experiment. It was also found that commercial extracts of meat and of yeast have a similar activity in smaller degree. By a method used by Kutscher (see Proceedings 1906, 624) in the examination of extract of meat, the authors succeeded in separating the physiologically active base from ergotinum dialysatum. It has an intense action on the uterus, and gave Tauly's reaction with *p*-diazobenzene-sulphonic acid. This, together with the conditions under which the base was precipitated with baryta in the presence of silver nitrate, suggested that it was a derivative of "histidine," which, itself, was found to be inactive, but acquired a trace of activity on heating, and became markedly so when ex-

Ergot—Conflicting Physiological Observations with the Same Preparation.—John C. Umney calls attention to a remarkable divergence of opinion concerning the pharmacological activity of a sample of fluidextract of ergot, which had been prepared from fine bold new Spanish ergot by the Pharmacopœia process and concentrated in vacuo, and contained the very high percentage of extractive of 18 Gm. per 100 Cc. It was submitted to different physiological experts, who reported their results within 28 days, and (in brevity) gave the following opinions: (1) "A poor specimen which has very little action on the vessels of the cat." (2) "I find the sample a very active one and in every way satisfactory." (3) "We have physiologically examined your specimen of liquid extract of ergot, and find it to be active and reliable."—Pharm. Journ. and Pharmacist, Dec. 25, 1909, 794.

Ergot—Presence of an Emulsin-like Enzyme.—I. Rosenthaler finds that ergot, in common with many other fungi, contains an emulsin-like enzyme. The presence of this can be demonstrated by adding the pulverized ergot to an amygdalin solution, which results in the formation of hydrocyanic acid in a short time. The enzyme is obtained in an impure condition by precipitating an infusion of the fungus, made with chloroform water, with an excess of alcohol. The hydrolytic action of the ergot emulsin, as compared with that of almond-emulsin, is however quite feeble.—Apoth. Ztg., xxv (1910), No. 1, 5.

Ergot—Instability Due to Enzyme.—Pointing out the well-known practical experience that ergot, which has been completely and rapidly dried, possesses greater stability than ergot which has been slowly and imperfectly dried, J. Schindelmeyer conjectures that the deterioration of the drug, resulting in the formation of a rancid fatty odor, a trimethylamine odor, and a reduction in physiological activity must be due to an organic body, which loses its distinctive activity, wholly or in part, by the thorough drying process to which ergot may be subjected. This view is apparently fully confirmed by the results of comprehensive experiments made by the author, which have determined that ergot contains at least two enzymes, the one having pronounced diastatic activity, the other hydrolyzing the fatty components of the drug, and that both enzymes lose their hydrolytic activity by prolonged keeping or by complete drying.—Apoth. Ztg., xxiv (1909), No. 89, 837–838.

Ergot—Extraction of Fixed Oil with Petroleum Benzin.—The observation of A. Rathje that the fixed oil of ergot when extracted by ether contains as high as 0.6 per cent. of alkaloid (see Proceedings 1909, 152) has led G. Fromme to make experiments with petroleum ether as being possibly a more suitable solvent than ether for the extraction of the oil, since, as is
well known, ergot deprived of the fixed oil retains its activity unimpaired for years if preserved with ordinary care. Having a large quantity of fixed oil extracted from reliable ergot with petroleum ether at his disposal, several portions, each of 250 Gm., were extracted with \( \frac{1}{2} \) per cent. hydrochloric acid, the acid solution supersaturated with ammonia and shaken out with ether. The residue of evaporation of the ether, dried to constant weight in the exsiccat or, approximated close to 0.015 per cent. of the oil employed in each case. It consisted of a varnish-like, brownish-yellow mass, which readily gave the reaction characteristic of cornutine—an intense blue zone when a trace of the substance was dissolved in chloroform, mixed with about 5 Cc. of ether and poured upon a layer of sulphuric acid. The ergot from which the oil was obtained contained 0.38 per cent. of alkaloid and the yield of oil was about 30 per cent.; consequently the amount of alkaloid extracted from the ergot with the oil did not exceed 0.0045 per cent.—a quantity that can properly be neglected in view of the stability that is imparted to the drug by the removal of the fixed oil.—Pharm. Ztg., liv (1909), No. 77, 758; from Caesar & Loretz Ber., Sept., 1909.

**FILICES.**

*Azolla Caroliniana—A Mosquito Destroyer.*—According to an interesting communication of R. Francé an aquatic fern, *Azolla caroliniana*, indigenous to the tropics, has in recent years been introduced into various regions in Europe for the destruction of the larvæ of mosquitos, gnats, etc., in ponds, ditches and stagnant waters. In these the plants develop with great rapidity, covering their surfaces completely, and effectually preventing the development of the larvæ into the insects. The plant is found on stagnant pools in Central and South America, also in the interior of Africa and some parts of North America, its small, light green leaves covering the surface of the water profusely.—Pharm. Ztg., liv (1908), No. 63, 612; from “Umschau.”

**GRAMINACEÆ.**

*Indian Rice—Composition.*—The results of analyses of 159 samples of Indian rice by David Hooper, show that the average percentage of protein in these rices is 7.25, with the highest in East Bengal and Assam and Bombay, and the lowest in Cuttack and the central provinces. But individual analyses have shown that the percentage varies from 9.81 in a sample from Broach to 5.44 in a sample from Cuttack. One object in conducting the examinations was to discover what natural circumstances have contributed to the superiority of the composition of the grain. In some cases the local reputation and market value of the rice coincide with the high nitrogen content; in other cases there is no such connection. The richness of the grain appears to be due not so much to the races of the plant or the appearance of the grain as to the cultivation. The grain of
finest composition is found in plants grown in rich virgin soil or in lands liberally manured. Instances of this kind are found in the red rice grown in taungya by the Chins of Burma, in the Kanapur rices of the Karnàtic, and in the Kasaragod rices of South Kanara on the western coast. The author thinks that attention to the cultivation of the rice plants in the way of manuring the land appears to be one of the principal means of improving the quality of the grain for commercial and edible purposes.—Pharm. Journ. and Pharmacist, Jan. 8, 1910, 27; Agric. Ledger, 1908-9, No. 5.

Rice—The Practice of "Facing" with Talc.—Dr. J. M. Hamill says that rice millers are generally not content with the appearance given to rice by milling, but endeavor to modify it in various ways by the use of extraneous substances during or subsequent to the milling, or by a combination of these procedures. The polishing material in general use is talc (French chalk) or steatite in the form of a fine powder. For commercial purposes these minerals are considered as identical, though in reality they exhibit a difference in structure, talc being distinctly crystalline, whereas steatite is crypto-crystalline. The talc may be added to the rice as it passes through the mills, and is probably used in the proportion of 1-150th of a gallon per ton of rice. The rice after this treatment is passed through the polishers, where it is claimed that the greater part of even this small quantity of talc added in the mills is extruded with the meal. The rice may then be treated with a glazing mixture, by which it receives a further accession of talc. Such glazing mixtures are usually composed of talc, glucose and glycerin, and the quantities of the glaze used appear to vary according to the kind of appearance which it is desired to give to the grain. Figures relating to the amount of talc found on the rice after the above methods of treatment show that the talc added during the milling was without appreciable effect upon the mineral content of the rice, while the glazing process contributed approximately 0.2 per cent. of mineral matter to the finished rice. But sometimes additional talc is added to "dry off" the mixture, and the percentage of mineral matter might be increased to as much as 0.44 per cent. Small amounts of the polishing material are probably not injurious, but at the same time the presence in a food like rice of comparatively large quantities (1 to 2 per cent.) of insoluble and possibly irritating matter might in some circumstances be definitely prejudicial to health, especially as this food is often given in considerable quantities to children and invalids. Pharm. Journ. and Pharmacist, Feb, 19, 1910, 205; from Rep. Inspectors of Food, 1909, No. 8.

Straw—Disinfectant Value in a State of Incomplete Combustion.—A. Trillat draws attention to the disinfecting power of the gaseous products of the incomplete combustion of straw. The principles of disinfection consist in the presence, in acid medium, of aldehydeic and polyphenolic derivatives produced during incomplete combustion of the straw. Their
formation is due to the oxidizing action of the gases of the combustion on the carbon of the straw at a high temperature, the carbon constituting a very energetic catalytic agent promoting production of formaldehyde in a more or less polymerized state. The proportions of the aldehyde found on examining the evolved gases vary, according to conditions, from 200 Mgm. to 2 Gm. per kilogram of straw. To the formaldehyde formed the polyphenols also formed add to the antiseptic action, and, in addition, there is the presence of pyroligneous acid. It is known that the antiseptics, particularly formaldehyde, act much more energetically in an acid atmosphere. The maximum effect is obtained by avoiding too complete combustion, and for this purpose the straw should be arranged in the form of a heap made of alternate layers of the dry and moist material. The method is limited to the disinfection of caves, stables, sewers, tunnels, etc., since only space and surfaces can be disinfected in this way. The burning of straw as a means of disinfection is an old practice, but, as the author maintains, one founded upon true scientific principles.—Pharm. Journ. and Pharmacist, May 7, 1910, 571; from Compt. rend., 150 (1910), 339.

Sugar-Cane—A Source of Useful Wax.—Von Wynberg finds that the press-marc of sugar-cane, after expressing the juice in the process of sugar making, contains 12 per cent. of wax in the dry material, which is readily extracted by benzine, carbon disulphide, carbon tetrachloride or other suitable solvents. The crude wax thus obtained is yellowish or brown. By crystallization from benzine this is separable into two portions, one soft, light-colored and saponifiable, the other dark, hard and unsaponifiable. By purification a hard, shining, white crude wax, melting-point above 80° C., resembling carnauba wax, is easily obtained in large masses. The cane residue from the wax extraction contains over 30 per cent. of sugar, which is easily dissolved out by water.—Pharm. Journ. and Pharmacist, Oct. 2, 1909, 423; from Sucr. Indig., 1909, 51.

Andropogon Grasses—Cultivation Experiments in Ceylon.—At the instigation of the Agricultural Society of Ceylon, J. F. Jowitt has made experiments in the cultivation of Andropogon grasses in the Patanas (open plains) of Ceylon, at an elevation of 4,500 feet. In these experiments he employed the different varieties of citronella grass (Mana, Mana Pengiri and Lenabatu), also lemon-grass (Cymbopogon flexuosus Stapf and C. citratus (Stapf), as well as palmarosa and vetiver (khus-khus) grass and Cymbopogon polyneuros. Owing to the change in climatic conditions due to the high altitude, C. citratus was altogether a failure, and the greater part of the remaining grasses also flourished but poorly, the soil being insufficiently rich for the proper development of the plants. Better results were obtained after the use of natural and artificial manure, most of the grasses either requiring the application thereof before they showed any proper development, or the oil being improved both qualitatively as well as
quantitatively by the manuring of the plants. The latter result, for instance, was observed by Jowitt in the case of Mana grass, which in the green state only contained traces, and after drying slightly larger proportions of oil of an unpleasant odor. Artificial fertilizing caused a noticeable increase in the oil yield, and the oil, moreover, acquired a much improved odor, although one altogether differing from that of citronella oil.

With regard to the differences between Maha Pengiri and Lenabatu, Jowitt expresses the view that the two grasses differ not only in leaf, flower, and odor, but also in the peculiarity that the roots of Maha Pengiri are more on the surface, while Lenabatu is more deeply rooted. He therefore designates the two plants respectively as "surface feeder" and "deep feeder." For the distillation of the grasses Jowitt used a copper still of a capacity of 115 to 120 lbs., surmounted by a dome-shaped helm, the object of which was to avoid the passing-over of oxidation- and resinous products of high boiling-points. In order to prevent the singeing of the distilling material, the still was provided with a sieve-bottom, which was held in its place in a most primitive manner by placing it on two blocks of wood. Direct heat was applied, and the distillation was a so-called water distillation. The grass was reaped in the evening before it was distilled, and was placed whole in the still, as there was no advantage in cutting it up. For a full charge of grass, 30 gallons of water was added, but when the charge of grass was less, the addition of water was not proportionately smaller; for instance, for 50 lbs. of grass, 25 gallons of water was used. Each charge requires 4 hours to distil, the water which passes over first of all being returned to the still.—Schimmel's Semi-An. Rep., October, 1909, 42; from Agricultural Journ. of the Royal Bot. Gardens, Ceylon, iv, No. 14, 109.

Citronella Grass—Occurrence in the Wild State in Ceylon.—In his paper on the classification and the new nomenclature of the antropogon grass, (see Proceedings, 1907, 758) Stapf stated that citronella grass (Cymbopogon nardus, Rendle) only occurs in Ceylon in the cultivated state, and that its mother plant is probably "Mana grass" (Cymbopogon confertiflorus, Stapf; Andropogon nardus var., nilagricus, Hack.), which grows wild in Ceylon and is poor in oil. J. F. Jowitt now opposes these views. His investigations show that, besides mana grass, genuine citronella grass, C. nardus Rendle, also grows wild in Ceylon. Hence the surmise expressed by Stapf and referred to above appears to him of doubtful correctness. C. nardus Rendle, which occurs in a wild state, is identical with the so-called "old citronella grass" (Winter's grass, Maha Pengiri) and forms a species distinct from Mana grass. It is possible that a third variety, known as Lenabatu grass, has resulted from hybridization of citronella and Mana grasses. In these circumstances Jowitt considers it advisable to designate the Maha Pengiri variety as a separate species
under the name of *Cymbopogon winterianus*. In this case the name *C. nardus* Rendle should be applied only to the Lenabatu grass.—Schimmel's Semi-An. Rep., Oct., 1909, 41; from Annals of the Royal Botanical Gardens, Peradeniya, vol. iv, part iv, 185.

_Citronella Grass—Possible Effect of Altitude on the Oil Content._—According to A. J. Ullée several oil-yielding grasses, especially *Cymbopogon nardus*, *C. citratus*, *C. martini* and *Vetiveria zizanioides* are grown in the botanical gardens at Salatiga (S. E. of Buitenzorg, Java). The most important of these is *C. nardus*, or citronella grass. As the altitude of Salatiga is considerably above that of Buitenzorg, Ullée made experiments for the purpose of ascertaining whether this difference influences the character of the oils. He obtained by distillation 0.66 per cent. of an almost colorless oil with the following constants: \(d_20 = 0.8721\), \(a_0 = 30\degree 15'\), total geraniol (calculated by de Jong’s method 92.75 per cent., soluble in 1.5 vol. and more of 80 per cent. alcohol. The oil was distinguishable from the Buitenzorg distillates in the first place by its greater solubility, for according to de Jong the Buitenzorg oils only gave a clear solution with 3 vols. of 90 per cent. alcohol, which became cloudy when diluted to over 4 vols. As Ullée only obtained an oil yield of 0.66 per cent., whereas in Buitenzorg the yield ranged from 0.5 to 0.9 per cent., experiments were made at Salatiga to ascertain whether the oil content of the grass could be raised by suitable fertilizing. Out of four experimental fields, three were treated for this purpose with differently-composed artificial manures. The grass was cut after 10 weeks and equal quantities of it distilled in an exactly similar manner. The oil yields obtained ranged from 0.60 to 0.65 per cent., showing that manuring had not affected the oil content of the grass.—Schimmel's Semi-An. Rep., April, 1910, 41; from "Culturergids," Organ van het Algemeen-Proefstation van Java 11 (1909), 404.

_Palmarosa Grass and Gingergrass—Difficulty to Differentiate._—In his notes of a recent journey of investigation, Mr. J. H. Burkhill, of Calcutta, discusses the problem of differentiation between palmarosa grass and ginger grass—a question which has already frequently occupied botanists, but which up to the present has not been elucidated. According to Burkhill's observations, palmarosa grass (Motia) and ginger grass (Sofia) are doubtless different varieties of *Cymbopogon martini*, Staph, and in this view it is quite correct to designate them respectively as var. Motia and var. Sofia. It is however not easy to distinguish them from each other, as on the whole they are very much alike and their chief difference is a chemical one, the oils contained in them being different. It is practically impossible to notice any difference in dried specimens of the grasses, for which reason even so experienced a botanist as Staph was unable to recognize any variation in the two grasses. The subject is placed in quite a
different light, however, when the grasses are seen in the open in the place
where they grow. Here they are soon differentiated by their external
appearance, and after a time they can be distinguished even at a distance
of 15 to 20 yards. The reason of this is that the grasses do not grow
equally well in the same localities, as each requires a different climate and
soil. As a result, when they grow side by side and under the same con-
ditions they develop unequally, which makes it possible to distinguish them
without difficulty.

Burkhill found that Motia flourishes best on dry soil at the foot of the
hills or on moderately high slopes facing southwards and only slightly
wooded. Sofia, on the other hand, demands moisture and grows par-
ticularly well where this is supplied by plentiful dew or mist. It prefers
higher altitudes and wooded places, even as high as the hill tops, but it
may also be found at lower slopes, except those which face southward.
Very favorable places for Sofia are the teak forests (Tectona grandis L.,
East-Indian Oak) where, owing to the rapid evaporation of water during
the night, the air cools down to a considerable degree, and abundant dew
is formed. But in spite of all these individual preferences, both Motia
and Sofia may be found at any altitude, provided the other conditions are
Asiatic Soc. of Bengal, v (1909) No. 3 (U. S.)

PALMACEÆ.

Dried Bananas—Composition.—Dr. Max Winckel, extolling the value
as a food product of bananas dried after fully ripening on the plants,
thereby retaining aroma and attaining a maximum of sweetness, com-
unicates the results of an analysis of such peeled and dried bananas, supplied
under the designation of "Urwald-Banane," as follows: Water, 13.43 per
cent.; dry substance, 86.57 per cent. Ash, 3.43 per cent.; nitrogenous
substance, 5.57 per cent.; invert sugar, 67.27 per cent.; crude fiber, fat,
fruit-acid, etc., 10.20 per cent; substance insoluble in water, 9.35 per
cent. The peel amounts to about 40 per cent. in weight of the whole
fruit. With the exception of the crude fiber, the entire dried banana is
rapidly and easily digested. Its caloric value is 308, its nutrient value
783, and it therefore appears well adapted for and to constitute a cheap

ASPARAGNEÆ.

Asparagus—Two New Carbohydrates.—C. Tanret finds that the sub-
terranean parts and the green berries of asparagus contain two new carbo-
hydrates, which he has named respectively:

Asparagose and Pseudo-Asparagose.—The asparagose occurs in micro-
scopic spherocrystals which polarized light, while pseudo asparagose is
amorphous. Asparagose belongs to the group of carbohydrates (C₆H₁₀O₅)
nH₂O, approaching the limit C₆H₁₅O₅. Cryoscopic results indicate that the molecule is a multiple of 15 or 16 of this. When hydrolyzed it affords about 93 per cent. of levulose and 7 per cent. of glucose. Asparagose is not precipitated from aqueous solution in the cold by barium hydroxide solution; it is precipitated, however, by a strong tepid solution, and is redissolved in excess of the precipitant. It is thrown down, however, by barium hydroxide in the presence of alcohol, and is isolated by fractional precipitation of the purified aqueous extract of asparagus roots in this manner. Asparagose does not reduce Fechner's reagent, nor give a color with iodine. Yeast invertin attacks it very slowly. The juice of asparagus roots contains about 6.7 per cent. of this body. Pseudo-asparagose is obtained from the mother liquors after removing asparagose by evaporating to dryness, and extracting the residue with boiling methyl alcohol. The solvent is distilled off, and the residue fractionated with barium hydroxide and alcohol. It is more soluble in ethyl and methyl alcohol than asparagose. It yields 86 per cent. of levulose, and 14 per cent. of glucose on hydrolysis. It occurs in about the same quantity as asparagose. Neither of these carbohydrates are found in the shoots of asparagus as used as a vegetable nor in the ripe red berries of the plant.—Pharm. Journ. and Pharmacist, Aug. 7, 1909, 205; from Compt. rend., 149 (1909), 48.

LILIACEÆ.

Colchicum—Historical Study.—Dr. Gordon Sharp has made a comprehensive historical study of colchicum, tracing this valuable medicament through all phases of its application as a remedial agent, its botanical and pharmacognostic relations, its chemical, pharmacologic and therapeutic properties, from the earliest mention of the drug to the present day. This interesting paper must be consulted in the original, in Pharm. Journ. and Pharmacist, July 3, 1909, 5–6.

Colchicum—U. S. P. Assay of Seed and Corm.—While making colchicine on a large scale by a process similar to that of the assay process of the U. S. P., A. R. L. Dohme, H. Engelhardt, and Roland Schmidt found the yield of pure colchicine to be below the amount which should have been obtained according to the percentage of alkaloids determined as being present by the official assay process. Experiments following this observation prove, or was suspected that the colchicine obtained by the U. S. P. process of assay is by no means pure, especially that obtained from the corm, which in an assay of 8 samples showed impurities amounting to from 51.6 to 64.7 per cent., while in the case of 9 samples of colchicum seed the impurities amounted to from 32.2 to 41.9 per cent., as compared with the results obtained with a modification of a process, yielding pure colchicine, published by Panchaud in 1906 (Schw. Wschr. f. Chem. u. Pharm., 1906, p. 563). This process, as applied by the authors
Garlic—Constituents Producing the Volatile Oil.—According to Rundgoist, garlic contains a sulphurated glucoside, alliin, which is hydrolyzed by a special ferment, allisin, an oxydase, with the formation of fructose and essential oil of garlic. Alliin itself is not alliaceous in odor. Besides these constituents, garlic contains a peculiar carbohydrate. This is tasteless, is not colored by iodine, and gives a bulky precipitate with barium hydroxide. When hydrolyzed with dilute sulphuric acid it yields fructose. This carbohydrate was also isolated and described by Chevastelon in 1894.

The variation does not necessarily indicate the fraudulent addition of glucose, since the comparatively low price of colchicum seeds would hardly allow of a sufficient profit even if the highest quantity of glucose found were added, but the figures are important as showing a source of error if the strength of the tincture be judged from the amount of extractive yielded by it.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 51.

Garlic—Constituents Producing the Volatile Oil.—According to Rundgoist, garlic contains a sulphurated glucoside, alliin, which is hydrolyzed by a special ferment, allisin, an oxydase, with the formation of fructose and essential oil of garlic. Ornithogalum Thyroides—Proximate Constituents.—Frederick B. Power and Harold Rogerson have made a chemical examination of the entire flowering plant, including the under-ground bulbous portion of Ornithogalum thyroides—a South African plant, reputed to be poisonous, many deaths among horses having been attributed to it when mixed with forage. The results of the chemical examination prove the absence of an alkaloid. The plant yielded a very small amount of an essential oil to steam distillation. Other constituents found are: A sugar, yielding d-phenylglucosone and a dark resin, which yielded to various solvents the following bodies: Palmitic acid, pentatriacontane (C_{35}H_{72}), a phytosterol (C_{27}H_{46}O), a very small amount of volatile fatty acids, a small amount of the dihydric alcohol, ipuranol (C_{28}H_{36}O_2(OH)_2). The chloroform, ethyl acetate, and alcohol extracts were all dark colored, amorphous products, from which nothing definite could be obtained. The repeated poisonous properties of the plant have been fully confirmed, inasmuch as the administration of 5 Gm. of the ground air-dried material to guinea-pigs was attended with fatal results. The toxic principle appears to be chiefly contained in the resin.—Pharm. Journ. and Pharmacist, March 12, 1910, 326–328.

Veratrum Album—Toxic Effect of Contact with the Unripe Seed.—Ludwig Reinhard directs attention to the poisonous effect on the fingertips of a person who had touched the unripe seeds of Veratrum album. The effect manifested itself by a burning sensation followed by the formation of blisters, which were quite large and painful, but yielded to treatment in the course of a week.—Pharm. Ztg., liv (1909), No. 86, 852; from Münch. Med. Wschr., 1909, No. 40.

Iridaceae.

Saffron—Adulteration with Synthetic Coloring Matter.—Bettink directs attention to the adulteration of saffron with a nitro-coloring matter closely resembling crocin in color and gives two simple methods for its recognition. Evidently most of the crocin having been removed from the saffron by treatment with diluted alcohol, its original color was restored by means of the nitro-coloring matter. Saffron so treated resembles the unadulterated drug very closely, but it has a fainter odor and its color is not so dark orange brown, while it feels rough, not fatty, when handled. Water and ash content are approximately normal, and it gives also the characteristic blue color with sulphuric acid. The first method for detecting the nitro-coloring matter depends on its ready solubility in water (the crocin dissolving slowly) and the determination of nitric acid in the aqueous solution, which must for this purpose be obtained by shaking the sample not more than half a minute with water. The second method depends on the discharge of the yellow color due to nitro-coloring matter when a few drops of sulphurous acid are run into the aqueous solution obtained under the previous conditions.—Pharm. Ztg., liv (1909), No. 77, 757; from Pharm. Weekbl., No. 3, 1908, through Cæsar & Loretz Ber. Sept., 1909.
Ground Saffron—Percentages of Moisture and Ash.—An examination by A. Beythien of 120 sample of ground saffron showed the lowest percentage of moisture to be 5.01, the highest 12.25, and the average 8.90; 90 per cent. of the samples gave figures between 7 and 12 per cent. These figures represent the total loss on drying to constant weight, and therefore include the traces of volatile oil, which would be driven off. The ash of 112 samples was determined, and varied between 3 and 10 per cent.; omitting two samples which contained sand, the highest figure was 8 per cent., and this is regarded as a proper maximum limit. So-called "natural saffron" has been found to contain as much as 30 per cent. of styles, but such an article should not be regarded as genuine, or accorded recognition as a commercial grade.—Pharm. Journ. and Pharmacist, June 25, 1910, 788: from Ztschr. Untersuch. d. Nahr.-u Genussm., April 1, 1910, 365.

AMOMEACEÆ.

Ginger—Assay of Gingerol.—In a former communication (see Proceedings 1908, 185), H. Garnet and J. Grier had shown that in the assay of ginger the use of caustic alkalies for the purpose of combining the acid resins resulted in the partial or complete decomposition of the "gingerol" and then led to erroneous results. In their present work they tried sodium carbonate, ammonia, lime and magnesia, but found their use no advantage. They have employed light petroleum (b. p. 70° to 90° C.), pure ether (free from alcohol and water), pure acetone, pure alcohol and alcohol of 50 and 60 per cent., all of which dissolve the gingerol, but vary in the amounts of inert fatty, resinous or inert matters accompanying the gingerol, depending on the solvent used. The most complete extraction of the gingerol results with the use of pure ether, but in their extraction it is associated with inert fatty and resinous constituents. The ether is therefore removed by distillation, the residue boiled with repeated portions of petroleum spirit, and the petroleum spirit is shaken out with three successive portions of 60 per cent. alcohol, leaving in the petroleum spirit the volatile and fatty oil and much coloring matter. The alcoholic solution is then washed with a further portion of petroleum spirit, which removes the last traces of fat, etc., the alcohol is evaporated off or recovered, and the residual liquid shaken out with three successive portions of ether; the ether is evaporated off, and the gingerol weighed, after drying to constant weight in a water bath. The yield from Jamaica ginger was 1.1 per cent.; from Africa ginger, 2.0 per cent. The purity of gingerol is ascertained by its ready solubility in cold 1 per cent. aqueous potash solution.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 344–346.

ORCHIDEACEÆ.

Tahiti Vanilla—Characters and Constituents of Volatile Oil.—W. Busse
a number of years ago (1898–1899) surmised that the fruit of certain inferior varieties of vanilla, the so-called "vanillons," as well as the fruit of *Vanilla planifolia* Andr., which is cultivated in Tahiti, contains piperonal as well as vanillin. Schimmel & Co. have now made an investigation of Tahiti vanilla, in order to obtain a further knowledge of the aromatic principles contained therein. Preparing an ethereal extract from 9.2 Kgm. of this vanilla, and subjecting this to steam distillation after first removing the vanillin by means of soda liquor, 7 Gm. of a pale brown volatile oil with a pleasant characteristic odor were obtained, which showed the following characters: The oil was heavier than water; its b. p. lay between 105° and 118° C. (6 Mm.) 6 g. distilled over at about the b. p. of anisic alcohol, 115° to 118° C. (6 Mm.). Artificial anisic alcohol prepared from anisic aldehyde showed, at 5 Mm., a b. p. of 117° to 118° C. The fraction 115° to 118° C. of the vanilla oil contained, besides anisic alcohol, a little aldehyde, of which the semicarbazone melted at 204° C. With phenyl *iso*cyanate the fraction gave a urethane, m. p. 93° C., which was identical with the urethane from artificial anisic alcohol. When the fraction was oxidized with permanganate solution anisic acid was formed, m. p. 180° C. Free anisic acid was also detected in the alkaline extract of the vanilla extract. On the other hand, no piperonal could be discovered. The presence of anisic alcohol and anisic aldehyde, which are constituents of the odoriferous substances of the more valuable Bourbon vanilla could not be determined, but will be the object of further investigation with considerable quantities of raw material.—Schimmel’s Semi-An. Rep., October 1909, 142.

**ARISTOLOCHIACEÆ.**

*Mikania Guaco—A South American Snake Antidote.*—O. Tunemann identifies a South American drug introduced under the name of *Mikania Guaco* to be derived from a species of *Aristolochia*, for which he provisionally proposes the designation

*Rhizom. Aristoloeh. Paraguay.*—The drug consists of parts of the stem and rhizome of the plant and has the reputation of being an antidote for snake bite. The chemical examination reveals the presence of about 1 per cent. of volatile oil of a light yellow color and distinct acid reaction, having an agreeable mint-like odor and burning, afterwards cooling, taste. It is composed of a crystalline acid, a crystalline phenol, an ester, and a terpene. The drug contains no alkaloid.—Pharm. Ztg., lv (1910), No. 39, 396; from Gehe & Co., Spring Rep., 1910.

**LAURACEÆ.**

*Laurus Nobilis—Abortive Properties of the Fruit.*—E. M. Holmes mentions that in 1907 he identified some fruits which had been used for the production of miscarriage, to be laurel berries; the fruits, crushed and
swallowed with an infusion of parsley, producing the desired result. This use of the laurel berries is not mentioned in any work on toxicology or medical jurisprudence to which he has access, although this action of the plant was known to Dioscorides who states that the bark kills the foetus. The berries seem worthy of further investigation.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 52.

Camphor—Cultivation Experiments.—In the course of a report on the present position of the camphor-market, Cayla refers to experiments made by Campbell and Eaton at the botanical gardens at Batu-Tiga, Selangor, in preparing camphor from leaves. The plants were raised from Japanese seed, sown in May, 1904, and were transplanted in December, 1904. When 5 years old the plants were in excellent condition, most of them being 20 and some even 27 feet high. The leaves from these trees were dried partly entire and partly cut-up, and distilled moist, as were the twigs, which had been cut up into one-inch pieces. It was shown that the drying of the leaves (provided it be not done in bright sunlight), does not affect the yield of camphor, a conclusion which agrees with that arrived at some time ago by Giglioli. The distillate from the leaves consisted mainly of camphor, with only a small proportion of oil; the yield was considerably larger than that obtained from the twigs and the wood from the trunk, being, in fact, equal to at least 1 per cent. of the fresh green leaves. In comparative distillations, the yield of camphor from the various parts was as follows:

It follows that in the case of young trees the leaves afford the best distilling material, as the roots, of course, are not available for use. Three hours is a sufficient time for distilling the leaves and twigs (it is not stated for what quantity). In Formosa it is usual to continue the distillation of the chopped wood for 24 hours.—Schimmel's Semi-An. Rep., April, 1910, 27: from Journ. d'Agriculture tropicale, 10 (1910), 8.

American-grown Camphor is the title of an interesting article by R. H. True and S. C. Hood, which appears in the "Proceedings" of 1909 (pp. 719-721), from which it appears that all the evidence so far points toward a distinctly favorable outcome in the endeavor to produce camphor on a profitable basis.

Ngai Camphor—Variable Composition.—Schimmel & Co. have examined and report the results obtained with a sample of Ngai camphor recently received from Mr. R. S. Pearson, of Debra Dun, British India, from which it becomes evident that the constitution of Ngai camphor varies
considerably. Whereas a sample examined by them in 1895 consisted almost entirely of \( l \)-borneol, the present sample was found to contain about 75 per cent. \( l \)-camphor and only 25 per cent. oil. The crude product showed a spec. rot. \([\alpha]_b\) — 46.26° C. in a 54.18 per cent. solution of xylene, its m. p. being 175° C. After acetylation, the same xylene solution showed a saponification number of 46.4, corresponding to 13.2 per cent. of borneol. From this the borneol content of the Ngai camphor itself could be calculated at 24.4 per cent. The separation of the two constituents was effected in the usual manner by converting the borneol into its phthalic ester acid and driving off the camphor by steam. After repeated crystallization the two bodies were identified as \( l \)-borneol and \( l \)-camphor, with the subjoined constants:

1. \( l \)-borneol: m. p. 204° C., \([\alpha]_b\) — 35° C. (in a 20 per-cent. alcoholic solution).

2. \( l \)-camphor: m. p. 176° C., \([\alpha]_b\) — 43.15° C. (determined in a 50 per-cent. xylene solution); m. p. of the oxime 119° C. The solution of the oxime was dextrorotatory.

From the slight rotations of the isolated pure bodies it is to be inferred that the admixed yellow oil must be strongly lævorotatory, but it was impossible to polarize the latter, the available quantity being too small.—Schimmel's Semi-An. Rep., April, 1910, 148.

*Camphor—Borax Crystals as Adulterant.*—Attention is drawn by "Hz" to lump camphor adulterated with considerable quantities of borax crystals. The presence of the adulterant was not evident on superficial examination, since the borax crystals had acquired a strong odor of the camphor. The attempt to make spirit of camphor of course readily revealed the adulterant, but the public would be readily deceived.—Pharm. Zentrhi., 50 (1909), No. 35, 725.

*Seychelles Cinnamon Bark—Botanical Source and Constituents.*—In a previous report, Schimmel & Co. described a cinnamon bark oil from the Seychelles Islands and subsequently stated that the cinnamon trees in the Seychelles were originally introduced from Ceylon (see Proceedings, 1909, 309—310). Rosenthaler has now examined a sample of the bark, supplied to him by Schimmel & Co., and has ascertained that the bark differed from all other cinnamon barks known and described. More recently, however, Rosenthaler has procured young examination material from Mahé (Seychelles), and in conjunction with Reis he has continued his investigations on bark from the branches and trunk, from which it appears that anatomically the structure of the branch-bark agrees entirely with that of Ceylon cinnamon. The authors also give a precise, illustrated description of the bark from the trunk, and as this bark was derived from the same trees which produced the branch-bark, it follows that it, too, must be Ceylon cinnamon. The differences in the constitution of Ceylon
and Seychelles cinnamon oils, observed by Schimmel & Co., according to Rosenthaler and Reis do not apply to the question of origin, because in the matter at issue the bark is of different age and geographical origin. The following analytical results obtained by the authors show the chemical constitution of the bark from the trunk: Aqueous extract, 6.52 per cent.; alcoholic extract, 7.27 per cent.; total ethereal extract, 4.20 per cent.; volatile ethereal extract, 2.83 per cent.; non-volatile ethereal extract, 1.37 per cent.; protein matter, 2.04 per cent.; crude fiber, 36.04 per cent.; cinnamic aldehyde, 1.33 per cent.; water, 9.38 per cent.; ash (including 0.44 per cent. insoluble in HCl), 8.6 per cent.—Schimmel's Semi-An. Rep. April, 1910, 35.

Cinnamomum Loureirii, Nees.—Source of Cinnamon Used in Japan and Exported also from Annam.—In an exhaustive article on the cinnamon tree, its distribution and cultivation, as well as the distinctive characters of the volatile oils obtained from the different species (see Cinnamom oils under "Organic Chemistry," Cayla mentions, besides Cinnamomum cassia, Bl., and C. zeylanicum, Nees, a third species, C. Loureirii, Nees, which yields the cinnamon bark used in Japan. This species, he states, has long been grown in Annam, the trade in the product being in the hands of the Annamese and Chinese, who distinguish the following brands of cinnamon: Que-kep, from trees over 4 inches in diameter; Que-kien, from smaller trees and from trees which have been prematurely stripped; and Que-thank, from branches. Regarding the cultivation, the author observes that it would be possible to produce large quantities of good cinnamon in Further India, but it is not advisable to recommend the extension of cultivation, because heavy over-production is to be feared. Generally speaking, this industry is in the hands of the Natives, and this is the best way for securing the continuance of its profitability. Europeans should limit themselves to the trade in the produce. Schimmel's Semi-An. Rep., Oct., 1909, 37-39: from Journ. d'Agriculture tropicale, 9 (1909), 164.

Cinnamomum Mercadoi, Vid.—Characters of Oil from this Species, Occurring in the Philippines.—Bacon calls attention to a species of Cinnamomum, C. mercadoi, Vid., which occurs in many parts of the Philippines. The Tagal name for the tree is calingag. 25 kilos bark of such a tree from the district of Lanao, Prov. of Bataan, when ground, yielded 260 g. = 1.04 per cent. of a pale yellow oil, with an odor resembling sassafras, and possessing the following constants: d^15° 1.0461, a^15° + 4°, n^3° 1.5270. Aldehydes could not be detected either with bisulphite or with phenylhydrazine. Fractionation in vacuo at 10 mm. gave the following results:

Fr. 1 (77 g.) b. p. 119 to 124°, n^15° 1.5333.
Fr. 2 (92 g.) b. p. 124 to 130°, n^15° 1.5320.
Residue 11.5 g. n^15° 1.5278.
After repeated distillation at ordinary temperature the first fraction showed the following constants: b. p. 235 to 238° (760 mm.) d_{30}^{10} 1.0631, \( a_{1200} + 0.9 \), \( n_{0}^{20} 1.5335 \). Oxidation by means of chromic acid resulted in piperonylic acid, m. p. 227°. Heating with alcoholic potash and subsequent oxidation with permanganate yielded piperonal. From this it would seem fair to infer that the oil of this species of *Cinnamomum* consists almost entirely of safrol.—Schimmel’s Semi-An. Rep. October, 1909, 40 ; from Philippine Journ. of Sc., 4 (1909), A, 114.

*Cinnamomum Tamala*, Nees et Eberm.—Characters of Vol. Oil from the Leaves.—The leaves of this species of *Cinnamomum*, a medium-sized tree abounding in Southern Asia, were in former years met with in commerce under the designation of “the narrow *Folia Malabathri*,” but are now obsolete. A sample of oil, distilled by Mr. I. H. Burkill, of Calcutta, has been examined by Schimmel & Co., who report the following results: The lemon-yellow oil had a clove-like, and at the same time slightly peppery, odor. It possessed the following constants: \( d_{15}^{10} 1.0257 \), \( a_{0} + 16° 37' \), \( n_{0}^{20} 1.52596 \); phenol-content 78 per cent., soluble in 1.2 volumes and over of 70 per cent. alcohol. The phenols consisted of eugenol (m. p. of the benzoyl compound 69° C.). When freed from phenols, the oil had the high optical rotation \( a_{0} + 66° 40' \) and yielded a solid nitrite which, when recrystallized from ethyl acetate melted at 113° to 114° C. It contained therefore d-α-phellandrene. In respect of its high eugenol content it is closely allied to the ordinary oil from Ceylon cinnamon leaves.—Schimmel’s Semi-An. Rep., April, 1910, 122.

**MYRISTICACEÆ.**

*Mace*—Chemical and Microscopical Examination of the Powderea Drug.—“W.” recommends the method of Busse as being the most reliable for the chemical examination of powdered mace, the method depending on the deep red color produced by the action of alkalies in the coloring matter of wild ( = Bombay) mace. The test is carried out by immersing a strip of filter paper in an alcoholic tincture of the sample for half an hour, drying the strip in the air, pouring on boiling baryta water and again drying. In the case of true ( = Banda) mace, the upper layer of the paper assumes a brownish-yellow color, whereas in the presence of wild mace it becomes brick-red. The method is available for the detection of an admixture of 3 per cent. of wild mace. Under a microscopic lens of 50 diameters, the method becomes available for the direct examination of the powder. If to a little of the powder, triturated with water on the object-glass, some solution of KOH is allowed to flow, the luminous yellow oil-cells of the Bombay mace assume a purple-red color and are easily distinguished from the genuine mace powder associated with it even during parting.—Pharm. Ztg., liv (1909), No. 86, 851.
Genuine and Adulterated Mace—Analytical Data.—A. H. M. Muter and Charles A. Hackman contribute some valuable analytical data obtained with samples of genuine (Banda) Mace and of other varieties of mace—Java, Macassar, and particularly Bombay mace, the latter, so-called "wild mace" being usually employed for adulterating the powdered genuine mace. The tests made to detect Bombay mace in the powder were both qualitative and quantitative: (1) Microscopic appearance; (2) character of color produced by a drop of alkali on a slip of filter paper moistened with an alcoholic solution of the sample; (3) repeated extraction with fixed fractional quantities of 98 per cent. alcohol and treatment of each fraction with lead acetate—the addition of which fails to react after the third extraction of genuine (Banda) mace, but continues to produce precipitates or color after a 25th extraction of wild (Bombay) mace; (4) the quantitative tests mentioned in the table following:

Bombay Mace—Detection.—James W. Gladhill recommends the following as being the quickest and surest way of detecting Bombay Mace when it is mixed with other mace: An alcoholic tincture of the suspected material (1 Gm. to 10 Cc.) is made by maceration for 2 hours and filtration. On adding 5 Cc. of solution of chlorinated soda to 2 or 3 Cc. of this alcoholic tincture, carefully allowing it to run down the inside of the tube, a bright red color will appear at the point of contact of the two...
liquids, if Bombay nace is present. The color does not remain long, and disappears very rapidly when less than 1 per cent. is present: but the test is available with as little as $\frac{1}{40}$ of 1 per cent.—Proceed. Penna. Pharm. Assoc., 1909, 331.

**POLYGONACEÆ.**

_Rhubarb—Recent Inquiries into the Source of the Chinese Sorts._—E. M. Holmes remarks that the source of Shensi rhubarb cannot be said to have been identified with certainty. This rhubarb exhibits on the outer surface a network of white lines, especially in the soft pieces which has not been shown to occur in any of the plants cultivated in Britain as the source of Chinese rhubarb. It fetches the highest price in China, often costing as much as 60 taels per picul. Anyone who has examined a long series of Chinese rhubarbs must come to the conclusion that the drug is derived from more than one species. Szechuen rhubarb is evidently the product at least in part of *Rheum officinale*, judging from the information recently published by Mr. E. H. Wilson and Dr. A. Henry. It is collected, according to the former, on the Kiu-tsa-o-shan range of mountains, which separates the provinces of Szechuen, Kansu, and Shensi. Mr. Wilson found this species in forests 8,000 ft. above sea level, reaching its best at 11,000 ft. to 12,000 ft., but extending up to 14,000 ft., that growing in the open beyond the forests being preferred. Plants raised from seeds gathered by him in 1900 flowered at Kew, and were identified then as *Rheum officinale*. The same plant was found by Dr. A. Henry in Hupeh, at an elevation of 7,000 ft. to 9,000 ft. This rhubarb finds its way to Hankow, and is there classed with the Szechuen rhubarb.

Mr. Wilson's notes concerning the collection of the root are interesting. The oldest plants are selected, ten-year-old plants being considered the minimum age, although the roots of six to seven-year-old plants are not infrequently collected. The root is dug up during the latter half of September and in October, and the digging is continued until snowfall renders it impracticable. In some cases the root is also dug in spring, before the new growth starts. The Chinese consider the rootstock or erect rhizome better than the roots for medicinal purposes, and remove the roots and then peel and cut the rootstock transversely or longitudinally, and these pieces when dried form respectively the rounds and flats of the Chinese rhubarb of commerce. According to Hobson, the roots are usually gathered twice a year, just before the flowering season, in March and April, or after the seed has ripened in July and August, and strung on strings and dried under the eaves of the houses, pierced with holes, just as capsicum is in Hungary; but they are often, probably as the weather gets colder, dried on heated stones. At Tatien-lu, where the climate is very moist, it is partly dried over brushwood fires. The root is only trimmed roughly by the gatherers, and is further trimmed, sorted,
and graded by the dealers at Chungpa, Mien chu, Kuan-hsien, and Yachou. From Yachou it is brought on rafts to Kiating, and there placed on boats and carried to Chungking. The Chinese consider the Tatien-lu rhubarb as less valuable on account of the method of drying by artificial heat, and in this they are no doubt correct, since the exterior is dried before the interior, and the inside is often discolored and rotten in consequence. The knowledge of this fact led the Russians, when rhubarb came by way of Kiachta, to enlarge the string holes or to pierce the center with a large hole to ascertain its soundness. For the same reason pieces split open are shown in the rhubarb chests at drug sales in this country. On the other hand, the rhubarb collected about Sungpan, where the climate is drier, is trimmed and cut up and then hung up under the rafters and eaves of the houses to dry. The rhubarb from this locality, as well as that of N. W. Szechuen, generally finds its way overland to Chungpa and Mien-chu, and thence by boat to Chungking. Rhubarb is occasionally cultivated in the mountains of Hupeh and West China, as at Mount Ua, but the cultivated article is considered inferior to the wild. All rhubarb that comes via Hankow is classed as Szechuen rhubarb, and Mr. Wilson is of opinion that it is all produced by *R. officinale*. But the rhubarb in the north-west of Kansuh and the Kohonor district is, according to Przewalski, the product of *Rheum palmatum*, var. *Tanguticum*, growing at 10,000 ft. in ravines facing north, where the soil is loamy, and not on bare mountain slopes.

Rhubarb is also collected in Manchuria a specimen of which, obtained at Kiao-chow in the Shantung province, was recently presented to the Museum by Mr. J. B. Martin, a missionary in that district. It does not present the appearance of the Shensi rhubarb, is only roughly trimmed, and appears to have been dried by artificial heat, the end of the round and the inner side of the long piece being concave. The veining is less black than in the root of *Rheum officinale*, and the diameter of the round pieces is less than would be expected in roots of the age of six to ten years. Concerning the plant that yields Shensi rhubarb no accurate information is as yet available.—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 80.

*Rumex Ecklonianus, Meis.*—Constituents of the Herb.—Tutin and Clewer have investigated the constituents of the herb of *Rumex ecklonianus*, a plant indigenous to South Africa, where it is reputed to have medicinal properties. An alcoholic extract of the herb, when distilled with steam, yielded a trace of a substance which formed yellow prisms, melting at 159° C., together with a small amount of essential oil. The non-volatile constituents of the extract consisted largely of brown resinous matter, but the following definite substances were also isolated: Ceryl alcohol; a phytosterol, C_{36}H_{51}O apparently identical with rhamnol; palmitic, stearic oleic, linolic, and isolinolenic acids; a small amount of ipuranol,
C_{23}H_{38}O_{2}(OH)_{2}; kampferol; chrysophanic acid; emodin; and emodin monomethyl ether; together with traces of other crystalline substances and large amounts of inorganic salts. A sugar which yielded \(d\)-phenylglucosazine was also present in small amount, but no evidence could be obtained of the presence of a glucoside. The emodin monomethyl ether which was isolated was identical with that obtained by Perkin and Hummel from *Ventilago madrasapatana*, and with that prepared synthetically by Jowett and Potter. The dimethyl ether of chrysophanic acid was prepared, and obtained in the form of yellow prisms, melting at 190° C.—Contribution from the Wellcome Chemical Research Laboratories, in Proceedings of the Chemical Society; from Chem. & Drugg., Dec. 25, 1909, 971.

**CHENOPODIACEÆ.**

*Phytolacca Abyssinica*—Pharmacology.—Dr. G. D. Dawson’s investigation of *Phytolacca abyssinica*, which occurs chiefly in Abyssinia, Madagascar, South Africa, and Australia, shows that it contains a saponin and an alkaloid. Its action is considered to depend on saponin, while the alkaloid has a distinctly harmful influence on the heart, so that a product of the drug containing the saponin, but free from the alkaloid, would probably be a good preparation for clinical use. The saponin is regarded as the principle which may cause the drug to be useful as a cardiac tonic.—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 81; from Med. Chron. Nov., 1909, 71.

**PRIMULACEÆ.**

*Primula Officinalis*—Glucosidal Constituents as the Root.—A. Goris and M. Mascarè find that the fresh root of *Primula officinalis*, Jacq., when crushed, emit at first an anise-like odor, changing later to an odor reminding of methyl salicylate. An examination of the root revealed the presence of two new glucosides, *primverin* and *primulaverin*, together with a specific enzyme, *primverase*, which is apparently characteristic of the *Primulaceæ*, and not identical with either emulsin, myrosin, or betulase. Both glucosides are crystallizable and readily soluble in water and in alcohol, but differ in their solubilities in absolute alcohol and in absolute acetic ether—the latter solvent being utilized for their separation from each other by fractional crystallization.—Pharm. Ztg., lv (1910), No. 12, 120; from Chem. Zentralbl., 1910, No. 3.

**SCROPHULARIACEÆ.**

*Digitalis*—Historical, Chemical, and Clinical Review.—At the meeting of the Minnesota Pharmaceutical Association, 1909, Dr. Edgar D. Brown presented a paper covering historical, chemical and clinical observations concerning this important drug, which will be consulted with interest and profit by medical men as well as pharmacists in Proc. Minn. Pharm. Association, 1909, 74–80.
Digitalis Standardization.—In a paper presented to the Association at Los Angeles, Worth Hale, a member of the staff of the Hygienic Laboratory at Washington, discusses very interestingly the factors that are concerned in the standardization of digitalis leaves and preparations (see "Proceedings," 1909, 768–773).

Linaria Striata—Presence of a Cyanogenetic Glucoside.—E. Burquelot has determined that the presence of at least one glucoside is indicated by the biological method in Linaria striata. The amount of hydrocyanic formed as a hydrolysis product with emulsin is considerable, being equivalent to 0.1478 per mille of the fresh plant. Benzaldehyde occurs as well, accompanying the prussic acid in the distillate. The amount of glucose formed by hydrolysis is greater in proportion to the hydrocyanic acid than is known to result from the decomposition of any other cyanogenetic glucoside. It is probable, therefore, that besides this, a second glucoside occurs in the plant, which does not give hydrocyanic acid as well as glucose when hydrolyzed.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 701; from Journ. de Pharm. et Chim., 30 (1909), 385.

Veronica—Glucosidal Constituents in Several Species.—J. Vintilesco has determined the presence of glucosidal bodies in Veronica officinalis and V. chamaedris, in addition to a sugar, hydrolizable by invertin, a glucosidal body which is split up by the action of emulsin. The glucoside is apparently identical in both plants, and is found most abundantly during the growth of the plants, being diminished after maturity and by drying. The plants also contain soluble ferments, exercising their activity on cane sugar as well as on amygdalin and on salicin.—Pharm. Ztg., lv (1910), No. 20, 204; from Journ. de Pharm. et Chim., 1910, No. 4.

Solanaceae.

Solanaceae—Influence of Cultivation on Alkaloid Content.—It is usually assumed that the active constituents are more abundant in wild-growing plants than in the cultivated. J. Chevalier, however, finds the assumption to be erroneous, and that the reduction of activity is solely due to the fact that the cultivation is carried out without regard to the natural condition and nature of the soil. Under proper conditions, cultivated plants are at least equal in strength to the wild grown.—Pharm. Ztg., lv (1910), No. 39, 397; from Compt. rend., 150, 344.

The "Wonderberry" Plant (Solanum Nigrum?)—The bearer of an Edible Fruit.—E. M. Holmes calls attention to the fact that the black berries of Solanum nigrum or rather of a luxuriant form of the plant, asserted to be a hybrid, introduced by Luther Burbank under the name of "wonderberry," have been eaten as a fruit in some parts of the United States, and that this particular plant has found its way into England.
How far this cultivated form differs botanically from the ordinary weed of the gardens, has not been clearly defined, and it is possible that in some cases the ordinary wild form has been substituted in commerce for the "wonderberry." This brings up the question of the reputed poisonous qualities of these berries, about which considerable doubt exists amongst horticulturists and amateurs. So far as the evidence goes the berries have very rarely been credited with producing poisoning, and it is possible that in these cases the berries may not have been correctly identified. Moreover, while it is certain that solanine produces symptoms of poisoning, and was first discovered in Solanum nigrum, the poisonous effect of the berries has so far only been noticed, and this effect may be due to idiosyncrasy, since the amount of solanine present in the berries is estimated at 0.3 per cent., and experiments show that it requires 0.1 Gm. of solanine per kilogram of weight to kill a rabbit.—Pharm. Journ. and Pharmacist, Octob. 2, 1909, 422.

Belladonna Leaves—Loss in Drying and Alkaloidal Content.—J. G. Roberts reports the result of experiments made with fresh belladonna leaves cultivated at Fox Chase Pa., which shows a loss of 60 per cent. on drying in vacuo at 45° C, and, very unexpectedly, that the whole leaves with stems contained slightly more alkaloids than the leaves without stems and midrib, as shown by the following figures: Whole leaves, with stems undried, 0.096 per cent; dried, 0.285 per cent. Leaves, without midrib and stems—undried, 0.080 per cent.; dried, 0.239 per cent. These results are not in accordance with assays reported by other operators.—Proc. Penna. Pharm. Assoc. 1909, 182.

Belladonna Leaves—Adulterations with Scopola Leaves.—John Moser, Jr., calls attention to the frequent adulteration or substitution of belladonna leaves by the leaves of Scopolia carniolica, which resemble the genuine drug rather closely, but are readily detected if any of the fruit is present, this being the most characteristic feature. The author describes the distinctive character of the two drugs, and mentions that the alkaloidal content may or may not be abnormally high in a sample of belladonna leaves adulterated with scopola leaves.—Amer. Journ. Pharm. Dec. 1909, 578–579.

Belladonna Fruit—Percentage of Alkaloids in the Ripe and Unripe Berries.—In view of the liability of belladonna berries being eaten by children during the season when the fruit reaches maturity, J. H. Williams has determined the alkaloidal content of the fresh berries, both ripe and unripe, selecting two samples of each, these samples were crushed in a mortar and then extracted completely. The several extracts were then estimated for alkaloidal content, and from these figures the percentage of alkaloid in the fresh berries calculated. The following results were obtained:—
From these figures it will be seen that the percentage of alkaloids present in fresh berries either ripe or unripe of Atropa belladonna ranges between the limits of 0.107 and 0.132 per cent.—Pharm. Journ. and Pharmacist, Octob., 16, 1908, 473.

Stramonium—Assay of Leaves Before and After Flowering.—H. W. Eakle collected stramonium leaves from plants, full grown but before flowering, and from plants after flowering but before deterioration, and assayed tinctures prepared from these after drying, and from leaves obtained in the wholesale market with the time of collection not stated. The first specimen assayed 0.0176 per cent. mydriatic alkaloids, the second 0.02048 per cent., and the third (the purchased sample) assayed 0.0324 per cent. of alkaloids.—Amer. Journ. Pharm., May, 1910, 242.

Tobacco—Composition and Toxicity of the Smoke.—K. B. Lehmann distinguishes two currents of smoke; the principal, caused by the aspiration of the smoker, and the accessory, which occurs at the ignited end of the cigar or cigarette. The latter represents one-fifth of the total smoke. From 80 to 98 per cent. of the total nicotine present in cigars, and 95 per cent. of that in cigarettes, passes into the smoke. The pyridine eliminated is from one-fourth to one-third of the total formed by combustion. Cigar smoke contains more ammonia than that of cigarettes. The smoke which enters the mouth contains from 1 to 6 per cent. of carbon monoxide, but this has no influence on its toxicity. Nicotine is the chief poison, from 16 to 18 per cent. of the total nicotine of strong cigars, and from 10 to 12 of that from mild ones being absorbed by the smoker. Cigarettes are less toxic because the accessory current of smoke is greater. Cigars cut up and smoked in a pipe are more toxic than when consumed in the ordinary manner, because the principal current of smoke is greater under these conditions.—Pharm. Journ. and Pharmacist, Sept. 18, 1909, 365; from Arch. Hygiene, through Nouv. Remèdes, 26, (1909), 299.

Tobacco—Condition of Nicotine in Cigar Smoke.—To determine the question whether the greater part of the nicotine in cigar smoke exists in a free state, or combined with organic acids, I. Tóth has aspirated through a special apparatus the smoke of 300 cigars, and determined the nicotine, both free and combined. It was found that the total organic bases, calculated as nicotine, amounted to 8.786 Gm., while the bases combined with organic acids only totalled 0.661 Gm. In cigar smoke, therefore, 93 per cent. of the total nicotine exists in the free state.—Pharm. Zentralh., 51 (1910), No. 5, 92; from Chem. Ztg., 1909, 866.
ACANTHACEÆ.

Andrographis Paniculata, Nees—A Remedy in Kidney-Gravel.—Dr. M. Buysmann recommends an infusion of the leaves of Andrographis paniculata, Nees, as an excellent remedy for kidney-gravel. The plant grows wild and is also cultivated in Java.—Apoth. Ztg., xxiv (1909), No. 94, 885.

LABIATEÆ.

South African “Snake-bite” Plants—Problematic Efficacy.—G. E. Oliver says that of plants used as remedies for snake-bite in South Africa by the natives about half a dozen are pre-eminent, and of these two species of Leonotis and one of Teucrium may be mentioned as the most important. Much curiosity existed about the identity of these before Andrew Smith was able in his work to reveal their botanical source. Much importance was formerly attached to the discovery of these plants, especially in view of the numerous supposed cures which had been effected by their means from the bites of most deadly snakes. The belief that they actually do act as antidotes is very widely held, and especially by Europeans who have lived among natives and had opportunities of examining their customs. To doubt the matter would bring ridicule on the head of the sceptic. The three plants mentioned as the most important snake-bite remedies are

Leonotis ovata (Dutch, “Klip dogga”).
Leonotis Leonurus (Kaffir, “Umfinaicine”), and
Teucrium africanum (Kaffir, “Ubu-Hlungu,” “Benyushu”).

The first of these (illustrated in the original) differs from Leonotis Leonurus only in having ovate instead of oblong leaves, a smaller number of whorls of flowers (which are also slightly different in color), and in its shorter habit of growth. They belong to the natural order Labiate, and both, especially L. Leonurus, would adorn any garden with their tall half-woody stems bearing whorls of handsome orange-red flowers. In their application for snake-bite, however, care (so say the authorities) must be taken to distinguish between them, as it is the leaves of Leonotis ovata which are used and the root-bark of Leonotis Leonurus, an infusion being made in both cases. The former is more esteemed in viperine bites and the latter in colubrine. It is not easy to understand how these plants came to be used for the purpose for which they are noted. The leaves of Leonotis Leonurus appear to contain a principle similar to that of Indian hemp, and are occasionally smoked by Hottentots as a substitute for the wild hemp, producing intoxication and delirium. The leaves are not the part used, however, for snake-bite, and the root-bark from a cursory examination appears innocent of any properties other than would be possessed by a hundred other common roots.

Teucrium africanum is a low-growing shrublet (also shown in the original paper) with white labiate inconspicuous flowers and lobed leaves.
The plant is somewhat bitter to the taste and has a pungent odor characteristic of many English labiates when bruised. Considerable quantities of a decoction can be given without any apparent effect, and it is difficult to believe, without some scientific demonstration to the contrary, that this or the preceding could contain anything in the way of an active ingredient subtle enough to nullify or mitigate the deadly effect of snake-venom. Until some rational explanation of their action is forthcoming no medical man would be inclined to trifle with life where serum, or, at any rate, potassium permanganate or ipecacuanha, is accessible; and even these are said to be of no avail where a full dose of poison has been injected by a snake in normal health.—Chem. and Drugg., May 21, 1910, 90-91.

Flores Lamii—Yield on Drying.—A correspondent—M. R. in E.—calls attention to an incorrect statement in the drying-table of the "Pharmaceutische Kalender," regarding the yield of dry substance from the flowers of Lamium album L. According to that semi-official authority 5 p. of the fresh flowers should yield 1 p. dried, whereas, in the experience of the writer the yield of properly dried flowers, during the present dry year, was 1 p. from 7 parts of fresh flowers.—Pharm. Ztg., lv (1910), No. 44, 449.

Lavender and Spike—Varieties Grown in the District of Grand-Serre (Drôme).—Lamoth describes the varieties of lavender and spike oils produced in the district of Grand-Serra (Drôme), and advises the establishment of lavender plantation in the mountainous regions of that district. He classifies the varieties of plants grown, as follows:

1. The coarse or bastard lavender, a hybrid of Lavandula latifolia and L. officinalis var. fragrans, which is fairly common in the neighborhood of Lyons, and yields a coarse inferior oil.

2. The medium lavender growing at a higher elevation and L. officinalis var. fragrans. This yields an oil deficient in fineness.

3. The fine lavender growing at the highest altitudes and distinguished as L. officinalis var delphinensis.—Chem. & Drugg. Jan. 29, 1910, 151.

Peppermint—Cultivation in Different Countries.—As it is possible to introduce the cultivation of peppermint to advantage in many British Colonies, the Bulletin of the Imperial Institute (7 [1909], 184) published for general information a review on the cultivation of the peppermint plant and the production of the oil in the various countries concerned. As is well known, the largest quantities of peppermint oil are produced in the United States, Japan, France and England, smaller quantities being also obtained in Germany, Italy and Russia. The oil distilled in America and Europe is derived from varieties of Mentha piperita, while the Japanese oil is obtained from Mentha arvensis. Two varieties of peppermint are specially known, the so-called "black mint" (Mentha piperita var. vulgaris) and the "white mint" (Mentha piperita var. officinalis). The first-named is the hardier and produces a larger proportion of oil; the
latter yields less oil but of finer quality. The particulars covered by this review must be consulted in the original, a brief abstract being accessible in Schimmel's Semi-An. Rep. Octob., 1909, 100–101.

Java Patchouli Leaves—Oil Content in Different Stages of Development.—Continuing his investigations on the oil content of patchouli leaves in different stages of development, de Jong has made investigations of Java patchouli leaves similar to those made last year with Singapore leaves (see Proceedings, 1909, 324). These investigations have led to results similar to those obtained with Singapore leaves; the oil content increases up to the third pair of leaves counting from the top of the branch, and then gradually decreases. The comparative distillations which de Jong has carried out on the present occasion with material which had been submitted to various kinds of preliminary treatment are of particular interest. Both Java and Singapore leaves were employed. In one experiment he used quite fresh leaves; in another dried leaves; in a third fermented leaves; the quantity being the same in every case, calculated for green material. The stalks had been removed before the experiment, as they contain only little oil. The leaves were dried in shady places, being spread out in a layer 5 Cm. high, which was turned over daily until the leaves were quite dry and brittle. For the purpose of fermentation de Jong first half-dried the leaves and then placed them on layers forming a heap, which was covered with bamboo matting (Tetampa), weighed down with stones. The leaves were mixed together every day in order that the fermentation might proceed as uniformly as possible. The process was continued until the temperature inside the mass of leaves did not exceed that of the surrounding atmosphere. According to the degree of moisture of the leaves the maximum temperature observed was from 35° to 52°. A mouldy odor was usually observed, but this was removed by spreading out the leaves at the end of the fermentation process and only distilling them a few days later.

The distillation was carried out by steam (3 to 4 atmospheres). In every case the leaves, after being distilled, were freed from water by pressure, dried, and again distilled. The quantity of oil obtained from green leaves was very much smaller than that from dried and fermented leaves. The following table, showing the yield obtained by de Jong from Java leaves, is of interest:

<table>

</table>
From the above it is clear that it is quite useless to work up green leaves, because they only yield very little oil, and even in this case the principal quantity was obtained from the second distillation, that is to say, after the leaves had been dried. Much more considerable outputs, on the other hand, are obtained from dried and fermented leaves, almost the total oil contained in them being yielded by the first distillation, the second producing comparatively little oil. The total quantity of oil in dried and fermented leaves is about the same. As regards Singapore leaves, similar conditions prevail. In the case of a single distillation, 24 kilos of the leaves in a green state produced 20 Cc. oil, but after drying they yielded 77 Cc., and after fermentation 86 Cc. The small yield of Singapore as compared with Java leaves is due to the fact that in the former case the distillation took place at atmospheric pressure only. Schimmel's Semi.-An. Rep., October, 1909, 92–94; from "Teysmannia," 1909.

**BORAGEINEÆ.**

*Alkanet—Origination of the Coloring Matter.*—Ella Eriksson, after a brief description of alkanet root (*Alkanna tinctoria, Tausch., Anchusa tinctoria*), communicates the results of her studies on the occurrence and origination of the coloring matter, alkannin, on which authorities differ—some considering that it originates in the cortex cavities, while others find that it also occurs in the cell-walls. The authoress finds that this coloring matter invariably originates in the cell-content and does not penetrate the walls of the cell. Even in the germ-root isolated epidermal cells and the hairs belonging to them have a red color. These isolated colored cells combine at first to form a red longitudinal streak of the width of the single cell; then a two- or three-rowed layer of normal cork, containing no coloring matter, is formed on the inner side of the colored cells. In subsequent stages, after the entire primary cortex has been detached, both cork and coloring matter are formed in much greater abundance. It is noteworthy that, apparently, the formation of the coloring matter depends on the rupture of the tissues, for in all places in which it occurs, not taking into account the epidermis, the tissues are found to be more or less lacerated. The author infers from this that it is the function of the coloring matter to protect the wounds produced by the rupture of the tissues.—Pharm. Ztg., lv (1910), No. 48, 491; from Ber. d. D. Chem. Ger., 1910, No. 4.

**BIGNONIACEÆ.**

*Sesame Oil—Pharmacopœial Substitution for Olive Oil in Galenical Preparations.*—G. P. Forrester says that in view of the unsettled condition of the olive oil market it is interesting to note that many recent Pharmacopœias have considered the question of introducing sesame oil as a substitute for olive oil. The choice is certainly justified, as sesame oil pos-
sesses good keeping properties and has a pleasant taste, while the extensive cultivation of the seed in India, the Far East, Palestine, Africa, and also in Southern Europe, the rapid growth of the plant (which in many cases gives a double harvest annually), and the large quantity of oil thereby available, render this product less liable to market fluctuations. At present sesame oil is official in the Pharmacopoeias of Japan (1907), Hungary (1909), Servia (1909), Switzerland (1907), Austria (1906), Croatia-Slavonia (1901), Russia (1902), and Holland (1905). In the Belgian Pharmacopoeia of 1906, under "Oleum Officinale, Huile Médicinale," it is stated that any non-drying oil employed for alimentary purposes may be used, such as almond, olive, sesame, nut, arichis, cottonseed, maize, etc., oils. In the Indian and Colonial Addendum to the B. P., sesame oil is official instead of olive oil in India, the African Colonies, the Eastern Colonies, and the North American Colonies—a considerable portion of the British Empire. Curiously enough, it was dismissed from the United States Pharmacopoeia of 1905, although it was contained in the previous edition. The author enumerates and gives the formulas for ointments, liniments and plasters of the Austrian, Hungarian, Russian, Croatia-Slavonian, Dutch, Swiss, and Japanese Pharmacopoeias, in which sesame oil has been substituted for olive (see Unguenta under "Pharmacy").—Chem. & Drugg., April 16, 1910, 61.

GENTIANACEÆ.

Gentian Root—Influence of the Method of Drying on its Constituents.—Experiments made by E. Bourquelot and M. Bridal demonstrate that the wide difference in the composition of fresh gentian root and the dried root of commerce must be attributed to the action of ferments. The drying process per se contributes but little to the change. At all events, by adopting a rational method of drying, such as is employed for other medicinal drugs (drying by air), dry gentian root may be obtained which yields a powder containing the same substance—or at least the same quantities of glucoside and sugar—as does the fresh root. Such a powder, in fact, may be used with advantage for the preparation of gentiopicrin, for which heretofore the fresh root was considered necessary.—Pharm. Ztg., lv (1910), No. 18, 181; from Journ. d. Pharm. et de Chim., 1910, No. 4.

Gentian Root—Adulteration with the Rhizome of Rumex Alpinus.—W. Metlacher calls attention to instances of admixture of the dried rhizome of Rumex alpinus with gentian root. The structure is necessarily quite distinct from that of the true drug, although superficially it might be considered to resemble the root of Gentiana pannonica. The upper portion shows the scars of the fallen leaves, and the lower part the marks of the rootlets; the color is reddish-brown, and it has not the aromatic odor of gentian; its taste is astringent and bitter, quite distinct from that of the true drug. The application of a drop of caustic alkali to the freshly-cut
surface causes the production of a deep red color, due to the presence of a methylandraquinone. Gentian root does not give this reaction. The microscopical characters of the adulterant are minutely described and figured.—Pharm. Journ. and Pharmacist, Feb. 26, 1910, 237; from Pharm. Post, 47 (1909), 838.

**Chlora Perfoliata—Occurrence of Gentiopterin.**—The intensely bitter taste of all parts of *Chlora perfoliata*, led Em. Bourquelot and M. Bridel to the conjecture that this plant, belonging to the Gentianaceae, might contain a glucoside similar to that contained in gentian. They have experimentally proven this to be the case and have demonstrated the presence of *gentiopterin* in the aqueous extract of plants collected during the flowering period, from which they succeeded in isolating it in a condition necessary to establish its identity. Incidentally they find that the gentiopterin content is reduced in plants collected during the fruiting period.—Pharm. Ztg., lv (1910), No. 20, 204; from Journ. de Pharm. et Chim., 1910, No. 3.

**Apocynaceae.**

*Apocynum Androsaemifolium* L.—*Volatile Oil, etc., from the Rhizome.*—C. W. Moore has subjected the rhizome of *Apocynum androsaemifolium*, L., to thorough proximate examination and has isolated a series of interesting bodies, among them a volatile oil, aceto-vanillone, and a new glucoside (aceto-vanillone glucoside) to which he gives the names of “*androsin.*” The volatile oil was obtained by steam distillation from the alcoholic extract of the rhizome in a yield of 0.016 per cent. of the drug. It is pale yellow, has a strong persistent odor, and gave the following constants: sp. gr. 0.948; b. p. 130° to 250° C.; opt. rotation + 0° 50'. It gave a strong fufurol reaction. The aceto-vanillone (see apocynin, Proceedings 1909, 390) was detected in the distillate, but was obtained in considerable proportions from the non-volatile part of the alcoholic extract, and partly also from the aceto-vanillone glucoside, *androsin*, to which the author assigns the constitutional formula CH₃.CO.C₆H₅.OCH₃·O.C₆H₁₁O₃·2H₂O. The new glucoside dissolves readily in hot water and in hot dilute alcohol and being hydrolized by emulsin, it is shown to be a 3-glucoside.—Schimmel’s Semi-An. Rep. Oct., 1909, 24; from Journ. Chem. Soc., 95 (1909), 734.

*Adenium Hongkel, D. C.—A Poison Plant of the French Sudan.*—Em. Perrot and M. Leprince report the results of the chemical examination of floral parts of a plant used by the natives of the Upper Senegal, under the name of “Kidi-Saramé,” as a medicine and poison, which has been identified as *Adenium Hongkel*, D. C. The very poisonous hydro-alcoholic extract of the blossoms gave no reaction for alkaloids. Presuming that the poisonous component was of a glucosidal nature, the extract was exhausted with chloroform, the chloroform evaporated, the residue dissolved
in 95 per cent. alcohol, and the alcoholic solution precipitated with water. Repeating this treatment with chloroform, alcohol and water several times for the purification of the precipitate, a light yellow amorphous powder, melting at 84°-85° was finally obtained, which, however was not hydrolyzable by the usual methods and therefore not a glucoside. The substance is violently sternalitary and a powerful heart poison.—Pharm. Ztg. lv (1910), No. 30, 304; from N. Chem. Zentralh., 1910, No. 9.

Nux Vomica—Source of Adulteration from Australia.—G. Planchon and A. Juillet observe that the name "coroso" has been originally applied to the seeds of Phytelephas macrocarpa, commonly known as the "ivory-nut," which is largely used for making buttons. This has recently been detected on the Continent as an adulterant of powdered nux vomica, as pointed out by them (see succeeding abstract): but large and increasing quantities of so-called Australian "coroso" are now imported into Hamburg. Since Phytelephas is not a native of that country, and the Australian seeds, although possessing an ivory-like albumin, have very distinct macroscopical characters, differing from those of the true ivory nut, it was sought to identify their botanical origin. This is now traced to Metroxylon vitiense, which also is not indigenous to the Australasian continent, but is a native of the Fiji Islands. Australia is only an intermediate port of shipment of the nuts, which originally come from the Polynesian islands to Australia, and are sent thence to Europe. The histology of this nut is fully dealt with and figured in the original paper, published in Réport. de Pharm. 22 (1910), 97.—Pharm. Journ. and Pharmacist, April 9, 1910, 455.

Nux Vomica—Adulteration of the Powder with Negrito Nuts.—Having recently observed an adulteration of powdered nux vomica with olive kernels (see Proceedings, 1909, 181), Juillet, in collaboration with Professor Planchon, devoted some attention to the adulteration of this drug and have determined that notwithstanding the low commercial value of nux vomica the powdered drug was in most instances adulterated. In addition to well-known adulterants the authors have determined one not hitherto observed, this consisting of the endosperm of the seeds of Phytelephas macrocarpa, R. P. (Elephantusia macrocarpa, W.), commonly known as "negrito nut" or "vegetable ivory"—an adulterant which lends itself admirably to the purpose, since the endosperm of these seeds is both odorless and tasteless, is a waste-material of no commercial value, and notwithstanding the hardness of the intact seeds is readily reduced to powder when in form of chips. The new adulterant is however easily recognized under the microscope by the pronounced structural distinction from nux vomics.—Pharm. Ztg., liv (1909), No. 55, 538; from Rép. de Pharm. 1909, No. 6.

Spigelia—Sophistication with Phlox Roots.—John Moser, Jr., in an examination of nine samples of so-called pink-root, found two of the sam-
ple to be genuine *Spigelia* of fair quality, one of them to consist entirely of *Ruellia*, while five of them consisted entirely of roots which, from their microscopic structure and from the macroscopic appearance, correspond very closely to the available data on *Phlox*. This, on the whole, bears a rather close resemblance to *spigelia*, and like *spigelia*, its matted roots are apt to contain much dirt. The remaining samples consisted of about equal parts of the same root and of another which bore no resemblance to it. The author expresses the opinion that species of *Phlox*—probably *P. ovata* and *P. glaberrima*—are at present frequently collected and sold as *spigelia*.—*Amer. Journ. Pharm.*, Dec., 1909, 577–578.

"Pinkroot" is the subject of a historical paper by M. I. Wilbert, which appears in the "Proceedings," 1909, 1170–1173.

*Tai-tsa-ju*—A Chinese Antidote for Snake-bite.—Gehe & Co. call attention to a new drug, consisting of the roots, rhizomes and stems of a plant which O. Tunemann has identified as being probably derived from a species of *Logania*. The drug has a reputation in China as an antidote for snake-bite, but is also used for the treatment of lepra, itch and other skin diseases. It contains a yellow coloring matter and two highly poisonous alkaloids, the identity of which has not yet been determined.—Pharm. Ztg., lv (1910), No. 39, 396; from Gehe & Co.'s Spring Report, 1910.

**Sapotæ.**

*Bassia Longifolia*—A "Saponin-Digitalin" Glucoside in the Seeds.—The seeds of *Bassia longifolia*, popularly known as "mowrah seeds," are imported in large quantities from India on account of a high yield of an excellent oil used in making the better classes of soap. Owing to the bitter taste of the residue of expression, this is valueless for economic purposes of such seed residue, such as food for cattle, for example. Attention has recently been called to the highly irritating action of this cake meal when in contact with a cut surface or with the mucous membranes of workers who were engaged in the manipulation of the meal, which has on this account become the subject of a chemical and pharmacological examination by Prof. Benjamin Moore, Fred W. Baker-Young, and Miss S. C. M. Sowton. The results of this investigation revealed the presence in these seeds of a new glucoside belonging to the saponin-digitalin group of glucosides, which the authors have named

*Mowrin.*—This was found to be readily soluble in water or alcohol, but practically insoluble in ether. On hydrolysis it yields, among other products not completely determined, a hexose and an organic acid, which the authors have named "mowric acid." The glucoside was obtained as a pure white product by decolorizing an alcoholic extraction of the meal with charcoal, and adding an excess of ether to the decolorized solution, collecting the precipitate rapidly on a filter, and drying over sulphuric acid—the process of solution in alcohol, precipitation by ether, and
drying being repeated two or three times. Both the glucoside and its acid derivative are poisonous when administered hypodermically, the glucoside being more powerful than the acid. One of the most interesting properties of the glucoside, inherent to a less degree also in the acid, is the powerful laking effects upon blood corpuscles in a saline suspension.

—Pharm. Journ. and Pharmacist, Sept. 18, 1909, 364; from Pr. M. J.

Chicle—Character of Identity.—M. Bocquillon describes the following character of chicle as a means of identifying this gum resin, which flows naturally or by incisions from the trunk of Achras sapota, a tree growing in Mexico and Guatemala:—Acidity, 0; specific gravity, 1.010; entirely soluble in carbon disulphide, petroleum ether, and chloroform; insoluble in methyl alcohol. Alcohol dissolves 55 per cent.; ether, 44 per cent.; acetone, 47 per cent.; acetic acid, 50 per cent.; benzol, 65 per cent.; amyl alcohol, 27 per cent.; aldehyde, 40 per cent.; oil of turpentine, 80 per cent. On incineration it leaves 6.9 per cent. of ash composed of sulphates, chlorides, and carbonates of sodium and calcium. The new edition of the Mexican Pharmacopoeia gives the following composition of chicle, according to the analysis of Prof. Uribe:—Crystallizable resin, colorless, soluble in alcohol and in ether, 45; caoutchouc, 18; sugar, 9; gum, 7; starch, 8; red coloring matter and salts, 7; water and loss, 6, all in percentage.—Pharm. Journ and Pharmacist, May 14, 1910, 609; from Rép. de Pharm., March 10, 1910, 103.

Mimusops Djave—Economic Use of the Seeds.—E. Fickendey makes a report on the possible economic uses of the seeds of Mimusops djave, a tree growing in the Cameroun, whose wood is known and valued as "Cameroun mahogany." According to Büchter, the seeds are embedded in a yellow pulp when the fruit is ripe, which is a favorite food of the natives, but in the unripe or partly ripe condition the fruit contains a caoutchouc-like latex, which disappears entirely when the ripening is completed. The fresh seeds are white and odorless. The dried seeds yield up to 64.53 of a fat—"adjab butter"—of the consistency of lard, light brown in a molten condition, but congealing to a white mass, possessing great resemblance to the so-called "shea butter," and having also the same constants. It is regarded as being suitable as a food product and is particularly useful for stearin and soap manufacture. On the other hand, Krause considers the seeds to be poisonous and they are so regarded by the natives. He has prepared a saponin from them, in a crude condition, which gives all the characteristic reactions of the saponins. Nevertheless, the marc of the seeds from which the fat has been expressed may serve as food for cattle, for which they are very suitable on account of their high protein content (22.82 per cent.), if it is first extracted with hot water, which does not depreciate its food value.—Pharm. Ztg., lv (1910), No. 30, 396; from Tropenpflanzer, 16.
MYRSINEÆ.

"Lodua" or "Negei"—A New Taeniafuge.—Penschke recommends the fruits of a species of Embelia, known as "Lodua" or "Negei," for the removal of tapeworm. The active constituent of these fruits is embelic acid. The fruits are administered in a crushed form, the treatment sometimes requiring one or two repetitions.—Pharm. Zentralh., 50 (1909), No. 49, 1022; from Arch. f. Schiffs. u. Tropen Hygiene, 1909, No. 21.

STYRACEÆ.

Siam Benzoin—Constituents.—Professor Friedr. Reinitzer has made a comprehensive study of the constituents of Siam benzoin, which he contributed to the recent meeting of German Naturalists and Physicians at Salzburg. Inasmuch as benzoin exudes naturally as a milk-white body, the brown Siaresinotannol, regarded by Liedy as being the principal constituent, does not pre-exist but is a product of oxidation. Siam benzoin in loose tears is perfectly crystalline. It melts at 59° C., and when heated at 40°-50° C. in the dark gradually turns yellow-red, red, brown-red, and becomes amorphous. The pure crystals, which melt at 72.8°, are monoclinic and colorless, but also become red to brown and amorphous when heated to 40°-50° C. They are composed of the benzoate of a resinacohol which the author has named Lubanol, gives a green color with FeCl₃, and may by further benzoilation be converted into a new crystallizable body. The original body, Lubanobenzoate gives Liebermann and Salkewsky's reaction and a beautiful blue color when heated with chloralhydrate. Siam benzoin also contains a benzoate resembling Liidy's benzoëvitriol, but not identical, since it contains more oxygen, which the author has named Siaresinol. This crystallizes in handsome prismatic needles, melting at 279° C., and are dextrorotatory in alcoholic solution. Siaresinol produces a sodium salt which is sparingly soluble in water but may be crystallized in long handsome needles by means of which it may be isolated in a pure condition. It is not sensibly affected by oxygen, nor changed in color by heat at 40-50° C.; gives no color reaction with FeCl₃, but does give Liebermann and Salkewsky's reaction. Siam benzoin, finally, contains an amorphous benzoate, which is reddened even at the ordinary temperature, is readily saponified, subject to further benzoilation, and separable by means of CS₂ into two distinct bodies. By prolonged heating at 100° C. it is converted into Liidy's Siaresinotannol. The author, furthermore finds that

Sumatra Benzoin originally exudes also as a milk-white substance, and that Sumatra resinotannol must therefore be regarded as an oxydation product.—Pharm. Ztg., liv (1909), No. 80, 791.

COMPOSITE.

Ageratum Conyzoides and A. Mexicanum—Vaso-Constrictor Alkaloidal
Constituent.—J. Chevalier has isolated from Ageratum conyzoides an alkaloid, forming a crystalline hydrobromide, which has marked vaso-constrictor action, similar to that of ergot, but of very low toxicity and without action on the heart. The allied Ageratum mexicanum, of European gardens, contains the same base, but in smaller quantity.—Pharm. Journ. and Pharmacist, June 18, 760; from L'Union Pharm., 51 (1910), 211.

False Arnica Rhizomes—Examination and Comparison with Genuine Rhizomes.—E. M. Holmes observes that for some months past true arnica rhizome has been very scarce, with the result that other roots are mixed with it in considerable proportion, in some cases as much as 20 per cent. One of these roots was submitted to Mr. Bertram Cockburn for microscopic examination. This has twice the diameter of the true rhizome, and the tranverse section shows a woody center, with radiating wavy wedge-shaped rays of about equal thickness, which at once distinguishes it from arnica. The microscopic examination showed that the vessels and sieve tubes contain a yellow oily secretion, which is also present in large oil ducts placed intermediately outside the phloem, as in arnica. Only traces of inulin were observed in the sections examined. Large oblong sclerotic cells are present in the cortex of the false arnica, which afford an easy means of distinguishing it, if present in powdered arnica. The odor of the root and the tincture are very similar to that of true arnica.

The characteristics of the two rhizomes in powder may be thus described:

Arnica Montana.—Abundant parenchyma with inulin. Absence of large yellow sclerotic cells. Characteristic thin-walled multicellular brown hairs.

Coltsfoot—New Phytosterols in the Flowers.—T. Klobb, in the course of an investigation of the cholestrol alcohols of the Composite, has isolated two new phytosterols from coltsfoot flowers. One of these, melting at 117°-119° C., is not yet completely examined. The other, faradiol, is characterized by the presence of two oxygen atoms in the molecule, having the formula C_{38}H_{50}O_{2}, or C_{31}H_{52}O_{2}, or C_{29}H_{46}O_{2}. Unlike the phytosterols of chamomile and of arnica, these bodies are not found in the petroleum-ether extract of the flowers, but in the alcoholic extract. Faradiol crystallizes from alcohol in large orthochromatic prisms, and from acetone in rectangular tablets. The crystals containing alcohol of crystallization melt at 209°-211° C.; but if freed from this at 115°-116° C., the
residual phytosterol melts at about 238° C. Its $a_b = + 45.1^\circ$. Certain of its esters are described. These investigations show that the phytosterols of the compositeae may be classed in three groups: (1) Monovalent, $\alpha$-aerotatory alcohols, melting near 130° C., crystallizing from alcohol in lamellae, and generally forming hydrated crystals; (2) monovalent alcohols of high melting-point, crystallizing in needles; (3) bivalent dextro-rotatory alcohols, crystallizing from alcohol in large crystals melting at above 200° C.—Pharm. Journ. and Pharmacist, Feb. 25, 1910, 237; from Compt. rend., 149 (1909), 999.

**Spurious Echinacea—Probable Source.**—John Moser calls attention to a root of uncertain botanical origin which was offered in the New York market during the fall of 1909. The spurious root when in the entire state differs in certain features from echinacea, but yields a powder that has a very similar appearance, and in this form requires the aid of a microscopic examination. To facilitate this, the author gives a macroscopic and microscopic description of genuine echinacea root, which is derived from two closely related plants (Braunéria purpurea and Braunéria palüida) and of the spurious root under consideration, which must be referred to in the original paper. It may be said, however, that the principal difference was found in the sclerenchymatous tissue, and that the isolation of the sclerenchymatous fibers by means of Schultz’s macerating solution or by digestion with 10 per cent KOH solution, greatly facilitated the work and made it possible to detect minute quantities of the spurious root in admixture with true echinacea. In a note to his paper the author mentions that the characters of the spurious root examined by him are very similar to those of the root of Parthenium integrifolium to which attention has recently been drawn as appearing in large quantities in the St. Louis market, apparently intended as a substitute for or adulterant of echinaceae.—Amer. Journ. Pharm., May, 1910, 224–226.

**Insect Powder—Active Constituent.**—J. Fujitani’s comprehensive investigation of the chemical constituents of insect powder confirm the views of Sato (see Proceedings 1908, 211) that the activity of the drug is due to a syrupy body for which Sato had proposed the name of pyretol, but for which Fujitani prefers the name of

**Pyrethron.**—It is a neutral, amber-yellow, syrupy ester, containing no nitrogen, insoluble in water, acids or alkalies, but very readily soluble in alcohol ether. It is readily decomposed spontaneously, and on saponification splits up into

**Pyrethrol, C$_{21}$H$_{34}$O, and several acids which have not yet been well defined. Pharmacological experiments prove that the insecticidal activity and the toxicity in general of insect powder is solely due to the pyrethron, which is regarded to be a nerve muscle poison, having in some respects toxic properties similar to veratrine.—Pharm. Ztg., liv (1909), No. 71, 691; from Arch. f. exp. Pathol. u. Pharmacog. 6r, No. 1.
Tanacetum Vulgare—Constituents of the Extract.—A detailed examination of an extract of the flower heads of Tanacetum vulgare, prepared with 60 per cent. alcohol by H. Matthes and H. Serger, gave the following constituents: A brown resin soluble in ether and having a strong bitter taste; a resin insoluble in ether but soluble in alcohol; another resin insoluble in alcohol; and fat, which contained glycerides of stearic, daturic, and lycopodium-oleic acids, and of an acid to which the name tanacetum-oleic acid is given, with traces of linolic, linolenic, and oleic acids; the unsaponifiable portion was found to contain phytosterin, melissyl alcohol, an unsaturated hydrocarbon, and other constituents that were not identified. The extract was light-brown, hygroscopic, and only partly soluble in water or absolute alcohol, but readily dissolved by dilute caustic alkalies.—Arch. d. Pharm., 247, (1909), No. 6, 418-431.

Rubiaceae.

Cinchona—Fungoid Disease in Java.—Dr. Rant gives an interesting account of a fungoid disease, known locally as "Djamoe Oepas," which attacks cinchona in Java. This disease is of great importance in connection with cinchona planting, but it is also found in coffee, tea, cocoa, nutmeg and Para rubber, and consequently interests planters in many parts of the world. The author states that cinchona suffering from the disease shows four fungoid growths, viz., (a) an incrustation (white in the dark, pink on exposure to light) which is Corticiuns javanicum, Zimm.; (b) small whitish nodules, made up of typical fungoid hyphae; (c) white translucent threads, forming a tissue resembling a cobweb; and (d) a mold, which is Necator decretus. A series of photographs of these forms is given in the original. Of the two typical forms, viz., (a) and (d), the first is generally found on the upper surface of cinchona branches and the second on the lower surface, but it is surmised that all four are forms of one and the same fungus.—Chem. & Drugg., Nov. 13, 1909; from "Teysmannia," 1909, 20, 409.

Cinchona—Improved Method of Assay.—Experiments made and described by H. Engelhardt and H. W. Jones lead them to suggest that the U. S. P. process for assaying cinchona bark might advantageously be changed, and they strongly recommend using the Keller-Fromme method in conjunction with the Panchaud titration of the alkaloids as modified by them. In case the determination of the ether-soluble alkaloids is again adopted the above suggested assay method should be modified and another factor for the alkaloids has to be used. This is not very difficult, inasmuch as in most of the cinchona barks the relation of the percentage of the four principal alkaloids of the drug is almost constant.—Amer. Drugg., Jan. 10, 1910, 5.

Pseudocinchona Africana.—Preparation and Characters of the Alkaloidal Constituents.—E. Fourneau describes the crystalline alkaloid from
the bark of *Pseudocinchona africana*, A. Cher., a rubiaceous plant having many affinities to the genus *Coryanthe*. The coarsely powdered bark is extracted with 5 or 6 times its weight of cold very dilute sulphuric acid, the solution is saturated with sodium carbonate, and the precipitate formed is collected and dried. It is then boiled with acetic ether, the ethereal solution filtered, concentrated in the water-bath and ether added. This precipitates a deep yellow crystalline magma, which is recrystallized several times from alcohol, when the alcohol is obtained in magnificent anhydrous, hexagonal, colorless plates. Crystallized from 60 per cent. alcohol, it contains water of crystallization. The white crystals become colored on exposure to light; they are alkaline to litmus, soluble in boiling chloroform, very soluble in boiling methyl alcohol, ethyl alcohol, and acetic ether, but little soluble in the cold liquids; very little soluble in cold absolute alcohol, benzene, ether, acetone; insoluble in petroleum ether, water, or in presence of alkalies. The melting point is difficult to determine, but it appears to lie between 241° and 242° C. With concentrated sulphuric acid it affords a colorless solution, which becomes brown after a few minutes. In dilute sulphuric acid solution it readily reduces potassium permanganate. Acid solutions of the alkaloid give a voluminous white precipitate with alkalies, insoluble in excess of the reagent and in ether, and becoming very quickly crystalline. The base is strongly lœvoro-tatory—a (D)$_{23}$ = −125° C. Analysis of the substance shows that it has the formula C$_{21}$H$_{26}$N$_{2}$O$_{3}$, which is the same as that of quenbrachine, but in spite of many points of resemblance between the two alkaloids, they should be considered as different, if only because of the rotatory power, which is dextrogyre in the case of quenbrachine. Various salts of the base have been prepared and are described in the original paper.—Pharm. Journ. and Pharmacist, May 21, 1910, 646; from Bull. des. Sci. Pharmacol., April, 1910, 190.

**Coffee—Content of Caffeine in the Raw and Roasted Seed.**—K. L. Lendrich and E. Nottbohm found, as the result of the analyses of 32 samples of coffee, the percentage of caffeine to be between 1.05 and 2.83 per cent. for raw coffee, and between 1.09 and 2.95 per cent. for roasted coffee, calculated in both cases on the dry material. Abyssinian Mocha contains the least caffeine, and Canzeno the most. The latter and Euconga coffee both contain over 2 per cent., and are derived from wild plants growing in Portuguese Africa. The highest percentages found in cultivated coffee were between 1.65 and 1.68. Only a few samples contained less than 1 per cent. The slightly higher percentage of caffeine found in roasted compared with raw coffee is due to loss of volatile matter and moisture during the process. Actually a portion, from 1.5 to 8.53 per cent., of the total alkaloid present is lost in the process.—Schweiz. Wschr. f. Chem. u. Pharm., xlvi (1909), No. 45, 692.
Coffee—Extraction of Caffeine Direct from the Green Berries.—L. Seissir has devised a method for removing the caffeine from coffee. About 5 kilos of unroasted coffee berries are placed in a closed centrifugal drum which is surrounded by a hot water jacket. After the addition of about 15 kilos of ethyl acetate, the drum is set in motion, so that the solvent and berries are thoroughly mixed, the temperature being maintained at 68° C. At the end of three hours the solvent is drawn off, and replaced by a further quantity of about 10 kilos, and the mixing and extraction are continued for a further two hours. The ethyl acetate is then run off, the berries are heated to 100° C. to remove the last traces of solvent, and finally dried at 40° to 46° C., the drum being rotated meanwhile. The ethyl acetate may be recovered by distillation, and the caffeine separated from the residue. The method is the subject of a French patent.—Pharm. Journ. and Pharmacist, Aug. 7, 1909, 205; from Journ. Soc. Chem. Ind., 1909, 622.

Morinda Longiflora—Medicinal Properties and Constituents of the Root and Leaves.—E. M. Holmes calls attention to the bark and root of Morinda longiflora which, under the name of "Ojuologbo," have occasionally during the last ten years been sent from Sierra Leone, Lagos, and other parts of West Africa, where it is regarded as a remedy of some value. It is stated to be a gentle stimulant to the cerebral centers, acting on the kidneys, and improving digestion and nutrition; it is used as a remedy for malaria. The root and leaves of the plant have been carefully examined by Mr. Barrowcliff and F. Tutin, and the results obtained were made known in No. 77 of the publications of the Wellcome Research Laboratory. According to these authors it contains a yellow substance, melting at 290°, which is a hydroxymethoxymethylanthraquinone C_{16}H_{12}O_{4}, crystallizing in yellow needles from absolute alcohol; a substance in pale yellow needles, melting at 209° C, which proves to be monomethyl ether of of alizarin, identical with that obtained from Chay root (Oldelandia umbellata, Linn.) by Perkin and Hummel, and resin, etc. The leaves yielded a new crystalline alcohol, morindanol, C_{16}H_{10}.O_{5}.OH.H_{2}O, melting at 278° C. Citric acid was found in the root, but not in the leaves. Experiments made in the physiological laboratory with extracts of the dried root and leaves upon small dogs yielded no definite effects of any kind.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 50.

Ranunculaceae.

Aconitum Lacinatum—High Percentage of Alkaloid.—E. M. Holmes states that a sample of fine tuberous roots of Indian aconite (A. lacinatum) was presented to the Museum of the Brit. Phar. Soc. of Great Britain by Mr. J. C. Umney, who had found then to yield by the U. S. P. the rather high percentage of 0.92 per cent. of ether-soluble alkaloids. The roots
were in excellent condition.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 51.

Cimicifuga Racemosa—Constituents of the Rhizome.—By the use of different solvents—water, petroleum ether, ether, chloroform—Horace Finnemore obtained solutions in which he identified the following bodies contained in an alcoholic extract of cimicifuga rhizomes: Isoferulic (hesperetic) acid; 3-hydroxyl-4-methoxycinnamic acid (m. p. 228° C.); sugar; tannin; four crystalline substances melting respectively at 153°, 200°, 225° and 260° C.; phytosterol; palmitic acid; liquid fatty acids containing oleic and other unsaturated acids; a trace of an alkaloidal body.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 265.

Coptis Teeta—Chinese Variety.—The rhizome of Coptis teeta, is used in Sind, under the name of "mamiran," for inflammation of the eyes, and well known in India under the name of "Mishmi Tita." It is stated in "Pharmacographia" that a variety of this drug is brought from China. The Chinese, however, distinguish two varieties—the one as Hwang-lien (yellow lien), the other as Chinese lien (lien from Szechuen). The attention of Mr. Burkill was directed a few years ago to these varieties, and he has now published an account of his researches, including some particular references to certain Japanese species, since the medicine used in Japan under the name of "Oren" is referred by Tsudioka and Mural to Coptis anemonaefolia. Mr. Burkill, giving an account of all the known species, with illustrations of the leaves and a résumé of the literature, considers the Chinese plant, which is cultivated at Ya-chou-fu, in the center of Szechuen, and Heoupin the eastern part, as Coptis teeta, Wall., var. Chinensis. The same plant was found by E. H. Wilson to be grown in the part of Szechuen adjoining Hupeh, by Henry in N. Wushan in the same province, and by Henry Leveson on the Burmo-Yunnan boundary. Mr. Burkill is also of opinion that part of the Japanese drug is obtained from C. brachypetala. Of the two kinds imported overseas into India he believes one to be Coptis teeta, var. Chinensis, the other C. anemonaefolia. If that be so, the former probably comes from Chinese and the latter from Japanese ports. The plants, cultivated or wild, in Japan, and referred to C. orientalis, C. occidentalis and C. occidentalis var. Japonica by various authors, should, he thinks, be studied in the living state for satisfactory discrimination, since the described species resemble each other very closely.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 671; from Journ. Asiat. Soc. Bengal, 1909, 73–88.

Larkspur and Stavesacree.—The microscopic distinction of the ripe seed of Delphinium consolida (larkspur) and of D. staphisagria (stavesacre) furnish the subject of an interesting paper by Charles W. Ballard, which, together with two full-page illustrations, exhibiting the microscopic characters of the two drugs, appears in the "Proceedings," 1909, 892–896.
UMBELLIFERÆ.

Parsley Seed—Unsaponifiable Constituents of the Fat.—In the examination of parsley seed fat by H. Matthes and W. Heinz, the yellow aromatic unsaponifiable portion showed a crystalline separation. On warming with a small quantity of alcohol the crystals were left insoluble. They were readily dissolved by chloroform and benzol; less soluble in ether, petroleum ether, and acetic ether. Recrystallized in tablets from ether, it melted at 69° C., and proved to be a hydrocarbon, C_{20}H_{63}, petrosilan. It does not afford any phytosterol reactions. Another crystalline constituent was isolated from the portion soluble in alcohol, separating from the solution in hot chloroform; this proved to be melissyl alcohol, melting at 88° C. From the portion soluble in cold chloroform a third crystalline substance was obtained by treatment with absolute alcohol; this melted at 133-145° and gave phytosterol reactions. The alcohol-soluble portion, after separating this, was a yellowish-brown liquid, with the Huebl value 111.75 and the n\textsubscript{d} 1.5154 at 40° C. Parsley-seed fat contains about 14 per cent. of these unsaponifiable constituents.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 671; from Pharm. Berichte, 19 (1909) 325.

RUTACEÆ.

Bitter Root from Sierra Leone—Identification and Constituents.—Under the name of "Dende," the bitter root of a small tree was presented in 1906 to the Museum of the Brit. Pharm. Society by Mr. Lort. Phillips, which was obtained by him in Sierra Leone, and which E. M. Holmes provisionally identifies as Brucea macrophylla, Oliv. The root is used by the natives as a remedy for malaria, and at the request of Mr. Holmes has been subjected to an examination for the presence of an alkaloid by Mr. H. Finnemore, who, by suitable treatment, succeeded in extracting a yellowish-brown crystalline substance which, when purified by recrystallization from absolute alcohol, melted indefinitely between 219° and 224° C.; but no evidence could be obtained as to the nature of these crystals except that they were free from inorganic matter.—Pharm. Journ. and Pharmacist, Jan. 8, 1910, 26.

jaborandi—New Substitution.—E. M. Holmes notes a new substitution of jaborandi leaves which in size and general appearance bear considerable resemblance to Rio Janeiro jaborandi (P. pennatifolius), but the leaves are rather thinner and have a tea-like odor. After a prolonged examination they were traced to the genus Cascaria of the N. O. Samydaceæ, but the large number of species of this genus made it impracticable to determine the species in the absence of flowers.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 52.

Jaborandi Leaves—Use of Chloroform for the Alkaloidal Assay.—Rupp and Zinnius having pointed out the liability of inaccuracy due to the decomposition of chloroform in the shaking-out process of assaying bella-
Xanthoxylum capense.

from 0.4 to 0.7

Genuine.

Quassia—Exhausted Wood on the Market.—E. M. Holmes says that quassia wood is now largely used to make an extract which enters into the composition of various insecticidal spraying liquids. The wood after extraction has been sold as quassia of second quality at a cheap rate. A sample of such exhausted quassia was presented to the museum by Mr. V. H. Kirkham, who examined it and found that it was not easy to prove legally that it was exhausted. Mr. Holmes asked him to compare it with authentic samples for the museum, and he arrived at the following figures:

<table>
<thead>
<tr>
<th></th>
<th>1 Museum P. S.</th>
<th>2 Bought.</th>
<th>3 Bought.</th>
<th>4 Exhausted.</th>
<th>5 Bark Genuine.</th>
<th>6 Medulla of Log.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moisture</td>
<td>9.5</td>
<td>9.7</td>
<td>9.9</td>
<td>13.5</td>
<td>11.2</td>
<td>10.4</td>

<td>0.3</td>
<td>0.4</td>
<td>—</td>
</tr>
</tbody>
</table>

It will thus be seen that the exhausted chips contain a larger percentage of moisture, nearly half as much again, and yield only about one-quarter of the amount of aqueous extract. The difficulty in distinguishing the exhausted from the official drug is that the bark and pith taken from a log in the museum, about 4 inches in thickness, yielded as little extract and nearly as much moisture as the exhausted quassia chips. The bark, however, could not possibly be confounded with the chips, and would not pay to collect separately, and the medulla forms too small a proportion to be worth consideration.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 51.

Xanthoxylum Capense—A Kaffir Antidote Against Anthrax.—G. E. Oliver figures and describes Xanthoxylum capense, a tree or shrub widely dispersed in the Cape Colony, which is chiefly interesting because of its universal use by the natives as an antidote against the ill effects of eating anthrax-diseased meat. Such meat is eaten by them with impunity, the feast being accompanied with draughts of an infusion of the root. This plant, known as "knobwood" and "wild cardamom," is characterized by the knobs with which the stem and larger branches are set. It is from these knobs that the vernacular names are derived—Puurde Pram (Dutch) meaning mare's teats. The leaves are imparipinnate, and their stalks and
nerves are usually armed with small prickles. The flowers, which are inconspicuous, are borne in pannicles and are unisexual and dioecious. The fruit is a dry one-seeded capsule, dehiscing in two valves and retaining the solitary black shining seed on its inner coat. This seed remains attached long after the valves have separated and shrunk. The plant itself is very variable in size and attains the size of a large tree in a dense high forest, while in other situations it is found only as a shrub.—Chem. and Drugg., Jan. 22, 1910, 115.

*Xanthoxylum Thunbergianum*, D. C., var. *Obtusifolia*—*A South African Snake-bite Remedy.*—E. M. Holmes has received from Mr. J. H. Yeo, of Potchefstroom, the root of *Xanthoxylum thunbergianum*, D. C., var. *obtusifolia*—locally called “paardipvam”—which is described by Mr. Yeo as a remedy for snake bite, and as the plant belongs to a genus, some of the members of which certainly have definite physiological action, as arterial stimulants and powerful diaphoretics, it may possibly deserve attention. "The local name signifies mare's teats, because the spines of the stem of the plant become thickened at the base until they look exactly similar. For snake bite the fresh root is rasped, and about ½ oz. of the scrapings is boiled in a pint of water down to 8 ozs. and strained. The dose of the decoction for a child of twelve years old is one teaspoonful every two hours. It has been proved to be most effective if given immediately after the patient has been bitten. Bites from all (South African) poisonous snakes, such as the puff adder, mambas, rink hals, etc., which usually cause death in from fifteen minutes to two hours, dependent upon the amount of poison absorbed, are quickly cured if the remedy be given at once, and in the case of small poisonous snakes where sufficient poison has been injected to cause serious illness, but not immediate death, it has a wonderful effect even after three days."—Pharm. Journ. and Pharmacist, Jan. 8, 1910, 25.

**Geraniaceae.**

*Linseed Meal—Quick Method of Detecting Impurities.*—The Bull. des Scienc. Pharmacol., 1910, No. 2, communicates the following simple and expeditious method of detecting adulterations and vegetable admixtures in linseed meal: 80–100 Cc. of benzin are poured upon 10.0 Gm. of the linseed meal, which, if pure, will remain on the bottom, whereas foreign (vegetable) admixtures, such as seed fragments, wood fragments, etc., will rise to the surface, and may be collected and weighed.—Pharm. Ztg., lv (1910), No. 28, 283.

**Sterculiaceae.**

*Kola Nuts—Varieties of the Ivory Coast.*—According to A. Chevalier, *Kola acuminata*, while met with in some districts of the Ivory Coast, cultivated by the Kroomen, is not a true native, having been introduced from Dahomey or from San Thomé. It is distinguished by possessing
three to five cotyledons, which form the nut. Its use and cultivation should not be encouraged, since it is of inferior quality. The trees which furnish the most esteemed nuts, those with only two cotyledons, are separable into three distinct varieties when the fresh material and growing trees are examined. They cannot be distinguished by dried herbarium specimens. One of these three varieties is *K. astrophora*, the red kola of the Ashantis. Its nuts are always red, and have two cotyledons. It is found on the Gold Coast and also on the Ivory Coast. The nuts of wild trees in the latter locality sometimes weigh as much as 70 to 90 Gm., although, when cultivated, they rarely exceed 15, or at the most 30, Gm. in weight. The second variety is *Kola alba*, a new species, the white kola of the Ngans. The nuts are at first white, then yellowish, and finally greenish after gathering. These white nuts are as highly prized as the red ones in the Soudan. The third variety, named by Schumann *K. vera*, is really a hybrid of *H. alba* and *L. astrophora*. It is the most widely spread and cultivated of all. It bears both red and white nuts on the same tree, and often in the same pod. It is not so deserving of culture as either the purely red or purely white kinds.—Pharm. Journ. and Pharmacist, April 9, 1910, 455; from Compt. rend. 50 (1910), 623.

*Kola Nuts—Sugar Content and its Determination.*—In order to determine the sugar content in fresh kola nuts, L. Bourdet, after the removal of the cotyledons, dried and powdered them and extracted the powder with alcohol. The alcohol is distilled off, the residue dissolved in water, the solution purified with basic lead acetate and Palein's reagent, and examined polarimetrically and volumetrically before and after inversion. The results showed a content of 0.748 per cent of reducing sugar before, and 3.252 per cent. after the inversion, calculated as glucose. The reducing sugar found before the inversion, according to its melting point and the characteristic form of the osazone prepared from it, must be regarded either as glucose or levulose, or a mixture of both.—Pharm. Ztg., lv (1910), No. 20, 205; from Bull. des Sciences Pharmacol. 1909, 650.

*Cocoa and Chocolate* and their uses in pharmacy are interestingly discussed by W. R. White in a paper published in the "Proceedings," 1909, 1014-1017.

**Ternstroemiacae.**

*American Tea—Production Beyond the Experimental Stage.*—J. Koch contributes an interesting paper on American tea farms in which he demonstrates that the successful cultivation and preparation of tea in paying quantities and of excellent quality has passed beyond the experimental stage. The question of cheap labor is an important factor, but it has latterly developed that, in places, there is much the same flora, the same climatic conditions, and the same cheap labor one has in the Orient. The paper contains much useful information connected with tea culture in the

HIPPOCRATIACEÆ.

Gurjun Balsam—Constituents.—Bacon has examined the balsam (Balao) from *Dipterocarpus grandiflorus*, known as “gurjun balsam,” thus complementing an investigation made by Clover some years ago. The balsam, when distilled under atmospheric pressure and *in vacuo* yielded an oil containing a mixture of crystalline acids, of which only a part was soluble in ether. In the fraction boiling at 128 to 131° (13 mm.) a sesquiterpene was also detected which, when distilled three times over sodium, appeared in the form of a colorless oil with the following properties: b. p. at ordinary press 261 to 262.4° (standardized thermometer entirely immersed in the steam), 118 to 119° (8 mm.), \(d^\circ_{13} 0.9104\) \(a_{DP} + 116.4°\), \(n_D\) 1.4956, ester no. and sap. no. 0, mol. refr. found 65.9, calc. for \(C_{15}H_{26}O\) \(\frac{2}{2} 69.15\). The sesquiterpene, according to these data, was bicyclic and double unsaturated. Attempts to obtain clearly defined derivatives of the sesquiterpene by means of bromine or hydrochloric acid gas, and to isolate definite products of oxidation by treating with permanganate failed, the latter experiment only yielding resinous bodies of aromatic odor. The terpene appeared to be sensitive to light to this extent that, after having been kept for 18 months in a stoppered glass bottle the rotation had fallen to + 101.2°, the other constants being almost unchanged.—Schimmel’s Semi-An. Rep., October, 1909, 136; from Phillipine Journ. Sc. 4 (909), A, 121.

MELIACEÆ.

*Chloroxylon Swietenia*, D. C.—Presence of an Irritant Alkaloid.—A specimen of East Indian satin wood, which is believed to be derived from *Chloroxylon swietenia*, D. C., has been the subject of investigation by E. M. Holmes on account of the irritant effect on being sawed, producing acute dermatitis, whereas this wood ordinarily does not produce inconvenience to the workmen. A microscopic comparison of this particular sample with East Indian satin wood known to be of non-irritant character, revealed no distinctions, nor could Mr. Holmes find any distinctive character that would indicate a different species on comparison of herbarium specimens of *Chloroxylon swietenia* grown at Hanbantota, known to produce the local irritation mentioned, and specimens of the plant in the museum. Further light is, however, thrown upon the subject by the chemical experiments of Dr. S. J. M. Auld, of the Imperial Institute, who finds that satin wood contains an alkaloid, which, on further investigation by Dr. T. Cash, is found to possess the same property as the wood in causing dermatitis in certain individuals. The alkaloid is a weak monoacidic base, several of the salts of which have been prepared and characterized. It melts at 182° to 183° C., is laevorotatory, and has been named “chlor-
oxylonine." It would appear, therefore, that the fact that some specimens of the wood like that of Hanbantota are more active than others, is probably on account of possessing a larger percentage of chloroxylonine.— Pharm. Journ. and Pharmacist, Aug. 28, 1909, 295.

SAPINDACEAE.

Kangalugi Root—A Native Remedy for African Tick.—H. Whippell Gadd says that “kangalugi root,” identified by E. M. Holmes to be derived from Deinbollea nyikensis, Baker, is used as a native remedy for African tick or spirillary fever of man. The remedy is made by mixing ticks (species “Ngññ”) with the bark of the root, the whole roasted on a shovel, and the burnt material reduced to powder. To produce immunity against the frequently fatal bites of this tick, and subsequent fever, scarifications of the skin are made in different parts of the body and some of the powder is rubbed in. The root is used also in the treatment of rheumatism, elephantiasis, vomiting, and as an aphrodisiac (in men only), being taken in the form of a decoction. On shaking the powdered bark with water ample frothing occurs, and a saponin in the form of a white crystalline powder has been isolated from it. This saponin, which has been examined pharmacologically by Dr. W. F. Dixon, is extremely irritant, and sets up vomiting and diarrhoea from direct irritant action on the alimentary canal. In small doses it produces little effect, but it appears to have a digitalis-like action on the heart. It is not, however, absorbed in any but the smallest amounts when taken by the mouth. On the whole it is disappointing as a therapeutic agent, and unlikely to be of any practical value.—Pharm. Journ. and Pharmacist, Dec. 25, 1909, 795; from paper read in the Therap. Sec. of the Royal Society of Medicine.

Sapindus Emarginatus—Characters and Quantity of the Saponin in the Fruits.—At the request of Mr. F. M. Holmes, Mr. J. C. Umney has undertaken the determination of the amount and character of the saponin contained in some nuts of Sapindus emarginatus, Willd. (?), which had been forwarded to the Museum of the Pharm. Soc. of Great Britain for this purpose. Mr. Umney reports that these fruits yielded 54 per cent. of pericarps and 48 per cent. of seeds. The dried pericarps were mixed with half their weight of magnesia and extracted with methyl alcohol. The solution was evaporated to dryness, mixed with magnesia, and again extracted with absolute alcohol. The yield of crude saponin was 49.9 per cent. of the pericarps. It was purified by precipitating it from the alcoholic solution by ether, repeating the process several times. When freshly precipitated it was nearly white, but on exposure to air it became reddish-brown in color, and was, therefore, extremely difficult to purify. The crude saponin was a brownish substance, very soluble in water, less soluble in hot alcohol, and sparingly soluble in ether. The aqueous solution was neutral to litmus, and gave no precipitate with acids nor with neutral or
basic solutions of lead acetate, and the lead process is not, therefore, of any use in extracting it. It produced considerable frothing, even in very dilute solutions. It appears to consist entirely of neutral sapotoxins, which, according to Bourcel and Chevallier, are decidedly poisonous; for medicinal use, therefore, it is not suitable. The difficulty of preparing it in a pure state would make it an expensive product to produce on a large scale, unless duty-free alcohol were used.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 50.

FUMARIACEÆ.

Corydalis Solida—Alkaloidal Constituents of the Tubers.—In a preliminary communication on the results of a chemical investigation of the tubers of Corydalis solida, G. Heyl states that he has so far isolated the following alkaloids from these tubers: Protopine (m. p. 207°): a base melting at 145° C.; and a base melting at 132°–133° C., but that the investigation of the two new bases is incomplete because of insufficient material. The protopine is contained in abundant quantity in the tubers, and was easily obtained in a pure condition, being readily separated from the associated bases by its sparing solubility in ether, and by its subsequent purification as hydrochloride. By recrystallization from very dilute chloroform alcohol solution, the protopine was obtained in the form of characteristic, shining transparent crystals, the identity of which was established by its characteristic reactions as well as by the elementary analyses of its hydrochloride and platino-chloride.—Apoth. Ztg., lxxv (1910), No. 5, 36–57.

Corydalis Aurea—Alkaloidal Constituent.—Dr. Georg Heyl has isolated from the rhizome, stems and leaves of Corydalis aurea a basic substance, crystallizing in white shining scales, melting at 148°–149° C., and readily soluble in alcohol, ether and chloroform. It was obtained by extracting the drug with 80 per cent. alcohol acidulated with acetic acid, evaporating, adding ammonia to the extract and shaking out with ether. The crystalline residue of evaporation was dissolved in alcohol, the solution carefully neutralized with hydrobromic acid, the hydrobromide obtained by concentration was again decomposed with ammonia and the liberated base recrystallized from diluted alcohol. The new base dissolves without color in concentrated H₂SO₄ and at first also in concentrated HNO₃ (sp. gr. 1.3), but becoming faint yellowish-red after some time with the latter reagent. It gives no color-reaction with Erdmann's reagent; produces an olive green color, gradually changing to blue-green in the margin, with Fröhde's reagent, and gives an olive to brownish-green color with Mandelin's reagent.—Apoth. Ztg., xxv (1910), No. 17, 137.

CRUCIFERÆ.

Capsella Bursa Pastoris—Galénical Preparations.—Dr. P. E. Hommell
directs attention to the probable therapeutic value of the herb commonly called "shepherd's purse" (Capsella Bursa Pastoris), "pickpocket" and "toywort," one of the commonest of weeds, growing along roadsides, on garden soil and along the edges of farm lands and fields. Regarding its constituents, besides the ordinary constituents of herbs, it yields a volatile oil identical with oil of mustard, and also contains about 6 per cent. of a soft resin. It is believed to possess therapeutic properties that make galenical preparations, properly made, desirable, and the author has therefore experimented to determine suitable formulas. As a result he proposes fluidglycerates prepared both from the "green herb" and the "dried herb," having found the latter, much to his surprise, to yield a satisfactory preparation, so far as can be judged from the odor, taste and acidity, notwithstanding that some writers regard the dried herb as being inert. These fluidglycerates are prepared according to the type formula of George M. Beringer, using ingredients in the following proportions:

Fluidglycerate Bursa Pastoris (From Green Herb).

<table>

Macerate the drug with the diluted alcohol for fourteen days, then express the liquid and filter. Dose, one to two fluidrachms, in water or syrup.—Proc. N. J. Pharm. Assoc., 1909, 48-50.

Lunaria Biennis—Alkaloidal Constituent of the Seeds.—According to Haines the seeds of Lunaria biennis—the so-called "garden honesty"—contains an orange-red crystalline alkaloid, or possibly a mixture of bases. After extracting the fixed oil, which is present to the amount of 30 per cent., with petroleum ether, the powdered seeds are extracted with boiling alcohol, the alcohol is recovered by distillation, and the residue taken up with aqueous tartaric acid solution. The acid solution is shaken out with chloroform, then rendered alkaline with sodium carbonate, and the alkaline solution shaken out by the same solvent, which yields the base or mixture of bases on evaporation. These are then purified by suc-
successive crystallization from alcohol and ether.—Pharm. Journ. and Pharmacist, May 21, 1910, 646; from Rép. de Pharm., 22 (1910), 172.

CUCURBITACEÆ.

Colocynth—Constituents of the Pulp and Seeds.—After reviewing the literature concerning the constituents of colocynth pulp, F. B. Power and C. W. Moore describe in detail the results of their examination, undertaken with the object of throwing further light upon the subject, employing for this purpose 105 kilograms of Turkish colocynth. Incidentally it may be remarked that the seeds, when separated as completely as possible from the pulp, were found to represent 75.5 per cent. of the weight of the entire peeled fruit. The results of the present investigation have established the fact that the so-called "colocynthin," "colocynthitin" and other products heretofore obtained from colocynth to which specific names have been attached were not pure substances, but very indefinite mixtures, and that the amount of glucoside substance present is extremely small. On the other hand it has been shown that the activity of colocynth is due to at least two principles, one of which is alkaloidal, although a very weak base, whilst the other source of activity is represented by some non-basic principle or principles contained in the ether and chloroform extracts of the resin, but which did not permit of being more definitely characterized. The colocynth contains, furthermore, a quantity of elaterin, but no evidence could be obtained of the presence of 3-elaterin, which is the physiologically active constituent of the fruit of Ecballium elaterium (which see).

Colocynth Seeds were found to contain traces of an alkaloidal principle, which was probably identical with that contained in the pulp, an enzyme which is capable of hydrolyzing β-glucosides, and, when extracted with light petroleum, they yielded 12.72 per cent. of their weight of fatty oil. This oil is a pale yellow liquid, and its constants as well as those of the total fatty acids were determined. Its composition is evidently very similar to that of the fatty oils of other cucurbitaceous seeds, such as the melon and the pumpkin. From the unsaponifiable portion of the oil a small amount of a phytosterol, C_{26}H_{43}O, was isolated. This melts at 158–160° C., and has \([\alpha]_{D} + 8.1^\circ\).—Chem. & Drugg., Jan. 29, 1910, 150; from Publications of the Wellcome Chemical Research Laboratories (Jan. 20, 1910).

Colocynth—Microscopical Examination of the Powder.—William Mansfield contributes a paper on the microscopic examination of powdered colocynth in which he describes the characteristic elements that serve for the recognition of the genuine drug, as also those of the rind and seeds, which should not be included in the powder. The paper is illustrated by cuts showing the microscopic elements of the rind, the seed, and the pulp respectively.—Drugg. Circ., Feb., 1910, 56–58.

Ecballium Elaterium—Chemical Examination of the Fresh Fruits.—
Dr. F. B. Power and C. W. Moore communicate the results of their examination of 27 kilos. of the fresh, nearly ripe, fruit of *Echallium elaterium*. From the alcoholic extract of this they obtained a resin, the constituents of which were a small amount of hydrocarbon (m. p. 68° C.); a phytosterol, \( \text{C}_{27}\text{H}_{46}\text{O} \) (m. p. 148° D.; \( [\alpha]_d + 3.2^\circ \)); a substance (m. p. 258°–260° C.) related to ipuranol, \( \text{C}_{27}\text{H}_{36}\text{O}_{4}(\text{OH})_2 \); fatty acids and a product corresponding to so-called “elaterin.” They confirmed Berg’s observation that the fruit contains an enzyme capable of hydrolyzing beta-glucosides, but, contrary to Berg’s statement, they found that elaterin exists in the fruit in a free state, and not as a glucoside (see Proceedings, 1909, 392). They propose to designate the laevorotatory constituent of crude elaterin as alpha-elaterin and the dextrorotatory as beta-elaterin. The latter is the physiologically active constituent.—Chem. & Drugg. Dec. 4, 1909, 862; from Proceedings Chem. Soc., 1909.

**Watermelon Seed—Chemical Examination.**—F. B. Power and A. H. Salway find that the chemical and physiological examination of watermelon seeds fails to indicate the presence of any definite active principle, although the seeds are popularly reputed to be diuretic. The kernels yielded to pressure 7.4 per cent. of fixed oil, and 19 per cent. to extraction with petroleum ether. The oil agreed very closely in composition with that obtained from pumpkin seed. The press cake yielded more oil, soluble proteids, sugar, and resin. From the last, a new alcohol, cucurbitol, \( \text{C}_{24}\text{H}_{40}\text{O}_4 \), melting at 260° C., was isolated. This is closely allied to grindelol, \( \text{C}_{25}\text{H}_{38}\text{O}_4 \), and ipurganol, \( \text{C}_{27}\text{H}_{34}\text{O}_4 \). These evidently belong to a homologous series, \( \text{C}_n\text{H}_{2n-2}\text{O}_4 \). The shells contained similar constituents, and the ash showed the presence of a distinct trace of copper.—Journ. Amer. Chem. Soc., 32 (1910), 360.

**MYRTACEÆ.**

**CLOVES—Direct Estimation of Volatile Oil and Eugenol.**—R. Reich has worked out a method for the direct estimation of volatile oil and eugenol in cloves. In an apparatus, described in detail, the powdered cloves, mixed with pumice and enclosed in a cartridge surrounded by a steam jacket, are exposed to a current of steam and distilled to exhaustion. From 1½ to 2 hours are required to complete the exhaustion of 10 Gm. of cloves, and from 600 to 800 Cc. of distillate must be collected. The distillate is then saturated with common salt and extracted with successive portions of from 25 to 30 Cc. of rhigolene (pentane), which has the advantage of not absorbing water. The solvent is then evaporated and the residual oil weighed—the entire operation being accomplished in from 6 to 8 hours. To determine the eugenol, from 1.0 to 1.5 Gm. of the oil are saponified for a quarter of an hour with 20 Cc. of a 5 per cent. soda solution in a condensing tube in a water-bath, with frequent shaking. After cooling the mixture, 20 Cc. of petroleum-ether with low boiling-point are
added and the whole well shaken. The clear petroleum-ether solution is removed, the residual eugenol-sodium solution adjusted to 30 Cc. by the addition of more 5 per cent. soda solution, and of this completely bright solution, 15 Cc. are now introduced into a shaking-cylinder, 5 Cc. of 5 per cent. sulphuric acid, 6 Gm. of common salt and 20 Cc. of pentane, are added, and the mixture is shaken continuously until it separates into two perfectly clear layers. An aliquot part of the pentane solution is then pipetted into a Mann weighing flask, and when the solvent is evaporated the residual eugenol is weighed. The author mentions the method of extraction and estimation of the oil as applicable to other volatile oils, but that not all of them are miscible with pentane (rhigolene) in any proportion, and that, therefore, the amount of solvent to be used must be determined in each case.—Schimmel's Rep., April, 1910, 43; from Ztschr. Unters. d. Nahr.-u. Genussm., 18 (1909), 401.

_Eucalyptus Leaves—Industrial Use in Tasmania._—H. I. Baker calls attention to a new use of eucalyptus leaves in Tasmania. While eucalyptus oil is distilled in Australia for medicinal purposes, and in New South Wales acetic acid is gained as a bye-product in this industry, but at Port Esperance the oil is obtained as a bye-product in the preparation of a more valuable extract. This extract is used as a preservative for boilers. It is miscible with water and frees the boiler from any acid and from fatty bodies and salts by forming an innocuous precipitate with these destructive ingredients and preventing incrustation. Four tons of eucalyptus leaves give one ton of extract and 70 to 80 lbs. of eucalyptus oil. Eucalyptus leaves are also recommended for use in gas manufacture. It is said that the bark can be employed in paper and tannin manufacture, as well as for leather-dressing, and the wood is very suitable for railway sleepers. —Schimmel's Semi-An. Rep., Octob., 1909, 67; from Consular and Trade Reports, No. 3415, 1909, 13.

_Melaleuca Leucodendron var. Lancifolia—Source of Cajuput Oil in Queensland._—R. C. Cowley, principal of Brisbane College of Pharmacy calls attention to _Melaleuca leucodendron_, var. _lancifolia_ as the probable source of cajuput oil in the Brisbane district of Queensland. It is a very common tree in the coastal districts of Queensland, growing in damp places alongside creek and water-holes. The name "Leucodendron" refers to the white scaly cork covering the plant, which is locally known as the "Ti-tree." It has a thick bark which is constantly exploiting thin papery layers of cork of a white color. This exfoliation of cork is characteristic of many Australian plants which are, like the ti-tree, provided with phyllodes in place of true leaves. These plants respire largely through the stem, and adopt this plan of keeping their lenticels open. According to Bailey, there are at least seven varieties of this tree growing in Queensland, but that growing in the Brisbane district is the one above
referred to. The yield of oil from this *lancifolia* variety is very small. A small quantity distilled by Mr. T. Ingham from this variety was quite colorless and had a pronounced cajuput flavor. Copper stills are not employed to distill cajuput oil, to avoid obtaining a blue-colored product. Mr. Ingham has determined the following chemical and physical constants: Sp. gr., 0.922; opt. rot. (100 mm.) — 3°; refract. index, 1.4623; cineol content, 45 per cent. According to Bailey ("Queensland Flora") the cajuput oil is also obtained in the East Indies from a form of *M. Leucodendron.*—Chem. & Drugg., May 28, 1910, 62.

**Japanese Pomegranate Barks.—Alkaloidal Content.**—Hirano has determined the alkaloidal content of the root-, stem-, and branch-bark of the Japanese pomegranate, following the method of the Japanese Pharmacopoeia. He found 0.32 per cent. in the root-bark, 0.12 per cent. in the stem-bark, and 0.1 per cent. in the bark from the branches. The author, furthermore, determined the presence of "mannite" in the ligneous parts of the plant.—Pharm. Ztg., liv (1909), No. 55, 538; from Journ. d. Pharm. Ges. v. Japan, May, 1909.

**Tamariscinae.**

**Tamarisk Manna—Properties.**—Dr. Hooper observes that, according to the researches of Ehrenberg and Hemprich, the gavan of Persia is *Tamarix gallica*, var. *Mannifera*, Ehrenb., and the aphid, which feeds upon it and produces the gez or manna, is the *Coccus manniparus* of Ehrenberg. As recent writers speak of the tamarisk manna as an exudation or secretion of the plant, the question of its production by insect agency must be left for further investigation. Since there are several kinds of manna, it is possible that some are produced by insects, and others, as the ash manna of Sicily, occur as saccharine exudations. Two samples of tamarisk manna have been received in the Indian Museum and examined. The first was a specimen of *tirmi* from Seistan, and the second was called *maki* or tamarisk manna from Dera Ghazi Khan. The *tirmi* was a soft, gummy, deliquescent substance mixed with a few small leaves. Alcohol separated a large quantity of sugar, reducing Fehling's solution and readily fermenting with yeast. The portion insoluble in alcohol was in white crystals and soluble in half its own weight of water. It melted at 140° C.: the solution was dextro-rotatory, and boiling with diluted acid caused inversion. The sample of *maki* from Dera Ghazi Khan was much darker in color, and white transparent crystals had separated out which were identified as those of cane sugar. The chief sugar of tamarisk manna is, therefore, not mannite, but a saccharose or cane sugar, as has been indicated by previous investigators. The samples contained only traces of nitrogen, estimated by Kjeldahl's process, proving that the exudation, as a food substance, is composed entirely of carbohydrates.—Pharm. Journ. and Pharmacist, Oct. 2, 1909, 423; from Journ. Asiat. Society of Bengal, New Series, v, No. 2, 1909.
Prunus Virginiana—Confusion with, and adulteration of, Prunus Serotina Bark.—John Moser, Jr., observes that, while it is generally believed that wild cherry bark is seldom or never adulterated, it appears that collectors frequently mistake Prunus virginiana, L., or "choke-cherry," for Prunus serotina, Ehrh., or "wild black cherry," which is the official source of wild cherry bark. This is a large tree, whilst Prunus virginiana is a tall shrub, bearing a red fruit having a very astringent taste. Both grow abundantly throughout the eastern and central United States, and the author's description of "choke-cherry" bark is therefore very opportune. It occurs in strips of various length, 1 to 4 Cm. wide and 0.5 to 2 Mm. thick; outer surface brownish green, with numerous large tentacles, 0.5 to 1.5 Cm. long; inner surface reddish brown, finely striate; fraction fibrous: inner color white; odor of bitter almond when moistened; taste bitter and astringent. The cross section shows numerous bast fibres, parenchyma containing spherical starch grains 2 to 3μ in diameter, tannin masses which are colored brownish by ferric chloride, and calcium oxalate in rosette aggregates of crystals 20 to 30μ in diameter. The powder is lighter in color than that from wild cherry bark and is distinguished by its numerous bast fibers which are 1.5 to 2.5 Mm. long, 12 to 20μ in diameter, lignified, and have a thin lumen.—Amer. Journ. Pharm., Dec., 1909, 579.

Wild Cherry Bark—Isolation and Characters of Glucosides.—As is well known, wild cherry bark (Prunus serotina, Ehrh., P. virginiana, Mill.), when stirred with water, yields an essential oil consisting chiefly of benzaldehyde and prussic acid. Although the constitution of the benzaldehyde points to the presence of a glucoside, attempts to isolate such a compound have not been successful. The fact, however, that Hérissey obtained from a closely allied species, Prunus padus, L., amygdo-nitrile glucoside (see "Proceedings," 1908, 407), made it probable that the same combination existed in Prunus serotina, and F. B. Power and C. W. Moore have now succeeded in proving that is, in fact, the case. These investigators have published the results of an examination of the constituents of bark of Prunus serotina, in which they state that in that portion of the alcoholic extract of the bark which is soluble in water, they have discovered the presence of l-am ygdo-nitrile glucoside (m. p. 145° to 147° C. from acetic ester, [a]b = -29.6° C.), although this body, it is true, only occurs in very small proportions. They also obtained tetra-acetyl-amygdo-nitrile glucoside, which, recrystallized from alcohol, melted at 136° to 137° C.; [a]b = -24.0° C. (in acetic ester). From the alcoholic extract they isolated by steam distillation, in addition to a small portion of benzoic acid, an essential oil, but in such a minute quantity that it was only possible to determine the b. p. (100° to 120° C. at 5 Mm. press.). This oil had a pleasant
aromatic odor, which was, however, altogether different from that of benzaldehyde. The bark yielded 0.075 per cent. of hydrocyanic acid, and contained a whole series of other substances, among them: (1) a phytosterol, C_{27}H_{46}O; (2) oleic, linoleic, isolinoleic, palmitic and stearic acids; (3) a small quantity of isopuranol, C_{28}H_{46}O_{3}, crystallizing from a mixture of pyridine and alcohol in needles melting at 285°-290° C.; (4) Trimethylgallic acid, C_{9}H_{14}O_{3}(OCH_{3})_{3}, m. p. 167°-169° C.; (5) p-coumaric acid.—Schimmel’s Semi-An. Rep., Oct., 1909, 127, and Rep. of Roure-Bertrand Fils., Oct., 1909, 142; from Journ. Chem. Soc., 95 (1909), 243.

Wild Cherry Bark— Constituents—In his paper on wild cherry bark, published many years ago, the late Professor Wm. Procter, Jr., demonstrated the formation of volatile oil and hydrocyanic acid under conditions which pointed out conclusively that their formation was due to an amygdaline glucoside and an emulsin-like albuminoid; also, that the bitterness was probably due to a glucosidal principle distinct from amygdalin. None of these were however obtained in an isolated condition. Henry Weimar now records experiments in order to throw further light upon the subject. His endeavor to isolate amygdalin in a crystalline condition failed of success; but he obtained an amorphous body (amorphous amygdalin) which gave all the reactions commonly attributed to amygdalin. In addition to this a fluorescent bitter substance, resembling but probably not identical with aesculin. He expresses the opinion that the bitterness of the bark is due to these two principles.—Proc. Arkansas Pharm. Assoc., 1909, 67-71.

Quillaia Bark—Spurious Varieties.—In the “Museum Report” for 1907, Mr. E. M. Holmes had drawn attention to a spurious quillaia bark, which differed from the genuine in being thinner, more brittle, and in having the surface covered with a thin brownish layer, marked with a coarse network of whitish lines. Since then he had received specimens of another quillaia bark in quilled pieces, with the genuine, which on analysis by Messrs. Wright, Layman and Umney was found to contain a larger quantity of saponin than even the genuine bark. The quilled pieces were from 3 to 6 inches long, about ½ inch thick, and ½ inch wide. The fracture does not show the characteristic laminae of Q. saponaria, and the substance of the bark is softer. At his request, Mr. Bertram Cockburn has made a histological examination of the three barks, referring to the false bark of 1907 provisionally as Quillaia pappigii and to the quilled bark as Quillaia smegmadermos, this being the only other species of the genus recorded from Chili, whence these barks are supposedly derived. Mr. Cockburn reports his results in some detail, from which the following recapitulation of the distinguishing characters of the three barks is taken:

Official Quillaia Bark.—Strands of bast fibers placed axially. Bast fibers, not usually extending from one ray to another. Medullary rays of
usually four rows of cells. Lignification confined to the lateral cells of the medullary rays. Starch grains few, $4\mu$ to $6\mu$ in diameter.

**False Quillaia Bark.**—Strands of bast fibers placed obliquely. Bast fibers usually extending from one medullary fiber to another. Isolated fibers not numerous. Medullary rays usually of three rows of cells. Lignification continued, as a rule to the third cell of the ray.

**Quilled Quillaia Bark.**—Strands of bast fibers smaller, rarely exceeding fifteen to twenty fibers. Isolated fibers of more frequent occurrences. Starch abundant and larger, $5\mu$ to $15\mu$ in diameter. Medullary rays usually of four rows of cells. Large irregular sclerotic cells in the cortex. Sclerotized cells almost absent in medullary rays.

Mr. Cockburn concluded from these results that the powder should be diagnosed by the amount of saponin present, and under the microscope, by the size of the starch grains, the relative abundance of sclerotized cells of the medullary rays, and of the irregular bast fibres, and in the case of the false quillaia bark, *Q. Poppigii (?)*, by the more pronounced reddish tint.—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 79.

**Soap Barks—New Varieties.**—“Micron” calls attention to the gradual disappearance of *Quillaia saponaria* bark from the market, and its replacement by a thinner, harder and darker-colored bark, which is said to be less rich in active chemical constituents than the genuine soap bark. From the closely similar laminated structure, crystalline deposits, and peculiar physical properties, it is inferred that the new bark is derived from a related species of *Quillaia*. Mr. Holmes suggests that the former source, *Quillaia saponaria*, having become exhausted, the bark of one or the other indigenous species is being substituted, and that the one under consideration is probably derived from *Q. Poppigii*. Another soap bark, less commonly met with, occurs in small quills or curved pieces about the size of those of canella or cusparia. Obviously this is a much younger bark and may be obtained from the branches of the official *quillaia*, or from *Q. Poppigii*, or possibly from a third species, *Q. Segmadermos*. The microscopic distinction of the two inferior barks are shown in cuts illustrating the author’s paper.—Chem. and Drrgg., Sept. 11, 1909, 443.

**LEGUMINOSÆ.**

**Bolivian Copaiba—Source and Properties.**—C. Hartwich describes a new copaiba of Bolivian origin, which is derived from a new species of *Copaiba* discovered by Herzog in Bolivia and described by him as *Copaiba paupera, nov. spec.* This is a tree about 30 meters high, which occurs sporadically in the forests of the province of Velazco, on the Rio Blanco. The copaiba is described by Hartwich as being of a light brownish yellow color, and of a viscous consistence, resembling the known varieties (particularly Maracaibo) both in odor and taste. It also resembles the latter
in its other properties, but in its optical behavior it offers marked differences, being in this respect more nearly related to African copaiba (see Proceedings 1909, 213), being like that dextrogyre, whereas all other copaibas are laevogyre. By steam distillation the copaiba yielded about 23 per cent. of volatile oil which gave the following constants: \( d_{150}^\circ 0.916, \ a_b^\circ +18^\circ, \ n_{D}^{20} \ 1.5048, \) acid no. 1.07, sap. no. (cold) 1.60. It is soluble in 9 vols. of 95 per cent. alcohol, as well as in ether, chloroform and petroleum ether. Liebermann's test gives at first a blue and then a green coloration; Flückiger's test a scarcely perceptible dirty color. When the oil was fractionated under ordinary pressure, about 70 per cent. passed over between 250° and 270° C. and about 10 per cent. over 270° C. Hartwich concludes from the constants that the principal fraction contains Caryophyllene and cadinene, but he does not mention any experiments for identifying these bodies.—Schimmel's Semi-An. Rep., October 1909, 135; from Schweiz. Wschr. f. Chem. u. Pharm., 47 (1909): 373.

*Myrocarpus Balsam—A Relic of Medieval Medicine.*—E. Schaer has examined a specimen of "myrocarpus balsam," an obsolete balsam of medieval pharmacopoeias, which had been handed down in a family. A comparison of the properties of this sample with the statements of ancient writers on natural history confirms his surmise that the article is identical with *Cabureiba* balsam, which was described by the Dutch physician, Willem Piso, about the middle of the seventeenth century, in his "*Historia naturalis Brasiliae,*" IV, 5, 57, and also with that called "*Baume du Pérou en coques,*" by Gibourt, in his "*Histoire naturelle des drogues simples.*" From the two species *M. fastigiatus*, Allem., and *M. frondosus*, Allem., of the *Myrocarpus* family, which are natives of Central Brazil, there exudes, either naturally or as the result of incision, a balsam which is caught up in the hollowed-out, walnut-sized fruits of certain palms or myrtaceae. After the contents have been left to dry for several days, the receptacle is closed with vegetable wax. The balsam itself is reddish-brown, and apart from its viscous consistency it showed great similarity to Peru and tolu balsam in its appearance and odor, as well as in its other properties. Among its constituents Schaer found both free benzoic acid and benzoic acid in combination with aromatic alcohols. On the other hand, neither cinnamic acid nor vanillin could be definitely determined as such. In this connection Schimmel & Co. observe that a sample of balsam which was sent to them a long time ago may also be a myrocarpus balsam, as all the details given by Schaer agree precisely with our sample, which was moreover also contained in a fruit the size of a walnut, and sealed with wax.—Schimmel's Semi-An. Rep., October, 1909, 138; from Arch. d. Pharm., 247 (1909), 176.

*Caragana Arborescens—A New Glucoside in the Leaves.*—The leaves of *Caragana arborescens*, Lamark, a native of the Ural Mountains, but long
cultivated in parks and gardens, are now found by E. Reeb to contain a bitter glucoside, which he has named Caraganin. It forms yellow scales or a yellow powder, and is hydrolyzed by acids with formation of glucose. Caraganin appears to be inert on the frog's heart. The glucoside was isolated from the dry alcoholic extract of the leaves, which was dissolved in a little water, and salted out with sodium sulphate to saturation. The precipitate containing the glucoside was extracted with alcohol, filtered, evaporated to dryness, and again redissolved in water. The salting out with sodium sulphate was again repeated. After three or four such treatments the glucoside is separated fairly pure. It was then further purified by treatment with lead acetate and filtered, and the excess of lead removed with hydrogen sulphide. Caraganin was then obtained by evaporation.—Pharm. Zentralh., 50 (1909), No. 35, 738; from Journ. d. Pharm. v. Els.-Lothring., 1909, 86.

Cicer Arietinum—Carbohydrates of the Seeds.—According to N. Castoro the seeds of Cicer arietinum contain saccharose, glucose, levulose and a new polysaccharide, \( \gamma \)-galactane, isolated from the extract obtained with alcohol, 70 per cent., by precipitation with absolute alcohol. It forms a white flocculent precipitate, and does not reduce Fehling's reagent until hydrolyzed with dilute mineral acids. It forms a glucosazone with phenylhydrazine, and gives the levulose reaction with hydrochloric acid and resorcinol. When oxidized with nitric acid it yields about 37 per cent. of mucic acid. Its \( a_p = +134.2^\circ C. \) to \( +144.66^\circ C. \) In addition to these sugars the seeds contain the hemicelluloses, para galacto-arabane and levulosane.—Pharm. Journ. and Pharmacist, Oct. 16, 1909, 474; from Gazz. Chim. Ital., 1909, 608, through Journ. de Pharm. et Chim., 30 (1909), 308.

Erythrina Zeyheri, Harv.—Botanical Description—Constituents of the Seeds.—Having received a herbarium specimen and photograph of a flowering twig of Erythrina zeyheri, Harv., a plant indigenous of the Orange River Colony, E. M. Holmes briefly communicates some of the botanical details and the results of a chemical examination of the seeds given by Mr. E. Langham, of Vrede, O. R. C. It is a prickly herb having an average height of 18 inches, the prickles being situated on the ribs of the stems and on the veins of the leaves, but are most abundant near the base of the stem. The trifoliate leaves, 3 to 6 inches long, have the lateral, oval leaflets smaller than the terminal subrotund one. The legumes are acrid to the taste, and contain poisonous principles, but lose these properties when boiled, and can be eaten like "legumes verts." The seeds have a scarlet testa, but do not give up their color to chloroform. They are used by the Kaffirs in South Africa for making necklaces. The average weight of the seeds is 20 grains. An analysis of the seeds was made, and they yielded 28 per cent. of a bland nutty flavored fixed oil, and 4 per
cent. of a volatile oil (erythrol), having a pungent odor recalling that of horseradish. The volatile oil is a powerful irritant. The mixture of the two oils in the natural proportions $28 \times 4$ speedily causes a pricking sensation when applied to the tongue. The volatile oil is soluble in alcohol and ether and distills at 60° C. It appears to belong to the butyl series of alcohols. The seeds also yield an alkaloid, which is insoluble in ether or benzol, for which the name "erythrine" is proposed. The fixed oil is aperient, but must be free from volatile oil, which is irritant and may prove useful for liniments.—Pharm. Journ. and Pharmacist, Jan. 8, 1910, 25.

Licorice Root—Collection in Bokhara.—A writer in "Pharmaceutische Zeiting" (liv, No. 87, 859) gives some interesting information concerning the distribution and collection of licorice root in Bokhara. The plant abounds on both sides of the Amu river and is particularly abundant in the neighborhood of Tschardshui, which is the center of the collection of the drug—the final drying of the roots and pressing into bales being conducted on a large scale in a plant erected and maintained by an English firm. The prices paid to the collectors living in the town and surrounding villages is ridiculously small (10 copecs per pud = 21.6 pounds). It is baled by hydraulic pressure into bales of 9–12 puds for export, mainly to Great Britain and the U. S.—the export in 1909 amounting to 9000 tons.

Sicilian and Russian (Uralsk) Licorice Root—Commercial Form and Botanical Source.—E. M. Holmes states that Sicilian licorice root arrives in English commerce in the peeled form and cut up into short lengths of about $3/4$ inch, and gives the following information, supplied by Mr. Arthur Barett, of Messina, concerning its preparation for the market: He states that the rhizomatous portion is preferred to the root, since it occurs in straighter lengths, and is, therefore, easier to peel. This operation is performed by women, and is by no means an easy one, even a practiced operator not being able to peel more than 20 pounds per day, and generally less. The waste and peel (and also the root) is used for making licorice paste. Sun drying is preferable to kiln drying, producing a lighter color. Regarding Russian licorice root, Mr. Holmes observes that a new species of licorice plant has recently been mentioned under the name of Glycyrrhiza uralensis, as yielding the licorice root of the Uralsk district in Russia, which differs in its bitterness and deeper yellow color internally, and reddish scaly surface, from that of western Europe, from G. glabra. Specimens of roots, fruiting stems and separate fruits of the Uralsk plant, examined by Mr. Holmes, prove these to be those of G. glandulifera, Waldst. and Kit.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 52.

Paranuts—Peculiar Change.—Having occasion to examine paranuts under the microscope, Dr. Hugo Kühl observed that the kernel of one of the nuts, which have a shining fatty appearance and milky color, had
acquired a completely crystalline appearance, resembling coarse-grained gypsum, and a bluish-white color. On nearer examination the presence of fungus tubes between the crystals became evident, and cultures obtained from it on sterilized honey solution proved this fungus to be *Aspergillus flavus* which, as well known, has poisonous properties.—Pharm. Zentralh., 51 (1910), No. 6, 106.

*Red Clover Flowers—Constituents.*—Frederick B. Power and Arthur H. Salway have made a complete chemical examination of the flowers of the common red clover—*Trifolium pratense*, L.—using for this purpose material collected during the month of June, each blossom having been separately gathered in order to exclude the green, herbaceous parts of the plant. The weight of the material, when fresh, was 264 kilos., and after careful drying amounted to 53.4 kilos. The dried flowers were completely extracted with hot alcohol, and, after the removal of the greater portion of the alcohol, the resulting extract was distilled with steam. A small amount of an essential oil was thus obtained, which possessed a rather unpleasant odor, and was found to contain furfuraldehyde. The portion of the alcoholic extract which was soluble in water contained a large amount of sugar, but from it a considerable number of definite crystalline substances were isolated, several of which are new compounds. These substances may be briefly enumerated as follows: Salicylic and *p*-coumaric acids; *isorhamnetin*, \(C_{16}H_{15}O_7\); *pratol*, \(C_{15}H_{16}O_5(OH)(OCH_3)\), which apparently is a flavone derivative; *pratensol*, \(C_{17}H_{20}O_4(OH)_3\); a yellow compound, \(C_{16}H_{20}O_7\); a substance, \(C_{15}H_{17}O_4(OH)_3\); a substance, \(C_{14}H_{12}O_3\); and the new glucosides; *trifolin* \(C_{22}H_{37}O_{11}H_2O\), which yields on hydrolysis a yellow coloring-matter, *trifolitin*, \(C_{16}H_{19}O_{10}\) and rhamnose; *iso-trifolin*, \(C_{22}H_{37}O_{11}\); and a glucoside which, on hydrolysis, yields quercetin \(C_{15}H_{10}O_7\).

The portion of the alcoholic extract which was insoluble in water consisted chiefly of resinous material, but from it the following definite compounds were obtained: myricyl alcohol, \(C_{21}H_{41}O\); heptacosane, \(C_{26}H_{50}\); and hentriacontane, \(C_{31}H_{64}\); sitosterol, \(C_{27}H_{46}O\) (m. p. 135°–136° C.; \([\alpha]_D\) = −34.4° C.) a new dihydric alcohol, *trifolanion*, \(C_{21}H_{35}O_2(OH)_2\); a mixture of fatty acids (consisting chiefly of palmitic, stearic, and linolic acids); and a small amount of pratol, \(C_{16}H_{12}O_4\), the last-mentioned having evidently been contained in the resin in the form of a glucoside. The dihydric alcohol, *trifolanion*, \(C_{21}H_{35}O_2(OH)_2\), is homologous with ipuranol, \(C_{22}H_{38}O_2(OH)_2\), and with the recently discovered citrulloc, \(C_{22}H_{36}O_2(OH)_2\) (from colocynth), the three compounds being apparently consecutive members of a series which is represented by the general formula \(C_nH_{2n+6}O_4\). In connection with the isolation of the above-mentioned substances from red-clover flowers it is of interest to note that at least three of these—namely, myricyl alcohol, and the hydrocarbons heptacosane and hentriacontane—are also constituents of beeswax, the chief component of
the latter being myricyl palmitate.—Chem. & Drugg., Febr. 12, 1910, 273; from Contribution of the Wellcome Chemical Research Laboratories.

*Tephrosia Macropoda—A Powerful South African Poison Plant.*—E. M. Holmes has examined the root, and some leaves of a plant were sent to the Museum a few years ago for identification by Mr. J. Newson, of Pietermaritzburg, in Natal. The leaves presented the characteristic appearance and silky surface of the leaves of several species of this genus, and the roots the fibrous character usually present. On comparison at Kew it proved to be the above-named species. Mr. Newson says that the native name is I'tyosaan (Kaffir). The point of interest about it is that a man who took an infusion of it in mistake for a root which causes vomiting, and is used by the Kaffirs when they feel queer, in two or three minutes after drinking the infusion fell down apparently dead. An English medical man who happened to be on the spot said that it was one of the quickest poisons to act that he had ever seen. He at once examined the native, who was a big, strong man, and who appeared to be dying, but after about ten minutes' artificial respiration the patient gave a big gasp, and in a few minutes got up and only complained of a very bad headache. It occurred to Mr. Holmes, in reading this letter, that the effects might have been due to *cytisine*, which Professor Plugge had found in several leguminous plants, and he sent the root to him for examination. Prof. Plugge replied that it did not yield cytisine, but that it contained a non-alkaloidal active principle which possessed the properties of a heart poison. The plant is evidently worth further investigation, which will, Mr. Holmes believes, be undertaken by Mr. L. Lake, of Verulam, Natal.—Pharm. Journ. and Pharmacist, Jan. 15, 1910, 50.

*Tolu—Satisfactory Test.*—According to Fleissig the various official methods for determining the free acid and saponification value of balsam of tolu are not so satisfactory as the following tests originally suggested by Merck: 1 Gm. of the balsam is dissolved in 50 Cc. of alcohol, and treated with 6 Cc. of \( \frac{N}{2} \) KOH solution; a little phenolphthalein solution is added, and then 200–300 Cc. of water. The solution should be distinctly red, or become so on adding 1 drop of the standard alkali. The excess of alkali may then be determined by titrating back with \( \frac{N}{2} \) HCl. To determine the saponification value, 1 Gm. of the balsam and 20 Cc. of \( \frac{N}{2} \) KOH are heated together on the water-bath for thirty minutes, then diluted with 200 to 300 Cc. of water, treated with 10 drops of phenolphthalein, and titrated back with \( \frac{N}{2} \) HCl. From 13.2 to 14.5 Cc. of the latter should be necessary.—Pharm. Journ. and Pharmacist, May 14, 1910, 609; from Schweiz. Wschr. f. Chem. u. Pharm., 47 (1909), 365.
Terebinthaceæ.

Manila Elemi—Source, Collection, etc., in the Philippines.—Regarding the question of the botanical source of Manila elemi, viz., Canarium lugonicum (Miq.), A. Gray, as being definitely settled (see "Proceedings," 1908, 243), Bacon declares that Manila elemi in the fresh state, as taken from the tree, is always soft, and only becomes hard after prolonged exposure to air and sunlight. This is in contradiction of the view of Tschirch, who distinguishes three varieties of Manila elemi, viz., hard, soft, and Tacamahac elemi. After giving some details as to the manner in which the Chinese conduct the trade in elemi, Bacon turns to the mode of collecting the gum. He states that it flows in the trunk of the tree chiefly when the tree is beginning to develop new leaves, and that in the principal place of production, viz., Atimonan, in the district of Tayabas, this takes place about January and June. During the rest of the year the tree is shedding its leaves and yields no resin. For the purpose of collecting the balsam the natives make incisions in the tree with tools known as bolos. The resin then exudes from the cuts and collects on the bark, from which it is removed once every few days, before it has grown dirty or hard. Bacon concludes from his own examinations that healthy, full-grown trees are capable of yielding annually 4 or 5 kilos of gum. One large tree produced as much as 22 kilos in 2 months. The production of essential oil from the various varieties of elemi, of different origin but of the same botanical derivation, was carried out by distilling the fresh gum in vacuo, separating the resultant oil from the water, drying with chloride of calcium, and again distilling in vacuo, in which process only the terpene fraction was considered, which was again distilled by Bacon under ordinary pressure. Of 62 samples, taken from different trees at Calaoq, in the district Tabayas, only two contained d-limonene: b. p. 174° to 176° C., and 175° to 176.5° C., a ñ + 89.0° and + 96° C., respectively. The other samples contained phellandrene; their boiling points varied from 168° to 179° C., and their rotation lay between + 134.5° and—60.6° C. So far as the technical details of the collection of elemi are concerned, the author states that the best means of cleaning the crude, and often dark and dirty gum, consists in dissolving it in benzene and in freeing the filtered solution from benzene by distillation. A pale product of the same scaly structure as elemi is thus obtained. Furthermore, the residue of resin remaining in the preparation of the oil appears to be suitable for preparing lacquers and varnishes, in which direction experiments are now being made, while on dry-distillation of this residue an apparently valuable resin-oil is also obtained.—Schimmel's Semi-An. Rep., October, 1909, 54-56; from Philippinne Journ. of Sc., 4 (1909), A, 93.

Rhus—What is the Nature of the Poisonous Principle?—L. E. Warren in an exhaustive review of the successive investigations regarding the na-
ture of the active poisonous principle of the different species of *Rhus* which are reputed to possess poisonous properties, says that the specific cause of rhus poisoning long remained a mystery, and even at present the problem is far from being well understood, either chemically or physiologically. An emanation or vapor, a gas, a volatile alkaloid, a volatile acid, an infection by bacteria, a non-volatile oil, a glucoside, a non-volatile acid resin, and a polyhydric phenol, have each in turn been accused of being the primary cause of the infection. So far as known all the poisonous species of *Rhus* (which are mentioned by the author) contain a viscid, pale cream-colored, emulsion-like juice which begins to darken at once on exposure to air, and eventually becomes black. Some information was gained by a study of the varnish-forming properties of the juice, but this knowledge found little application in elucidating the chemistry of the poisonous principle, which previous to 1830 was believed to be a volatile emanation from the juice, which itself was not otherwise poisonous. In that year Rafinisse proved that the poison sumac gave off *carbonated hydrogen* (!), must have suspected that the juice itself was venomous, because he enumerates "toxine resin" as one of the constituents. In 1858 Khittel isolated a "volatile alkaloid" to which he attributed the poisonous activity; but this could not be found by Maish in 1865, who attributed the toxicity of *Rhus* to a new volatile acid, "toxicodendric acid," and this was long accepted as being the true active constituent. In 1894-5, however, Pfaff was led to suspect the non-volatile nature of the poisonous constituents of *Rhus*, and having proven the toxicodendric acid of Maisch to be simply acetic acid, demonstrated the presence of a non-volatile oily body which he named "toxicodendrol" and proved to be the poisonous constituent of both ivy and sumac, present in all parts of the plant—stems, branches, roots, leaves, and fruit. In 1903-5 Tschirch and Stevens made an exhaustive examination of Japanese lac, the milk-sap of *Rhus vernicifera*, and established the non-volatility of the poisonous constituent, while Stevens and Warren subsequently (1907) showed the milk-sap of *Rhus vernix* to be analogous in almost every particular to the valuable Japanese lac. They describe the poison constituent of *R. vernix* as being a beautiful, clear, amber-red, oily, non-volatile liquid of sp. gr. 0.9693, soluble in aniline, amyl alcohol, acetone, acetic ether, benzol, petroleum benzin (b. p. below 50° C.), chloroform, carbon disulphide, carbon tetrachloride, ethyl alcohol, methyl alcohol, ether and toluol. It is very poisonous. Still more recently several Japanese chemists (Majima, Cho, and Miyama) have investigated the poisonous constituent of Japanese lac, which they have named "urushinic acid." From the analysis of the derivatives of this acid they conclude that it exists in the juice of the plant in a phenolic condition. In the purest state in which Mr. Warren has been able to obtain this resin (or oil) it is a clear, pale amber-red, adhesive, viscous, transparent liquid, of the con-
sistency of thick syrup, and having a distinct, characteristic odor. It is a powerful escharotic. In the properties of its esters and its behavior with ferric salts, its phenolic character is indicated. It is singular that none of its known compounds are poisonous.—Pharm. Journ. and Pharmacist, Oct. 30 and Nov. 6, 1909, 531 and 562.

**RHAMNACEÆ.**

*Cascara Sagrada—Yellow Volatile Constituent.*—F. H. Alcock, having obtained a yellow-colored distillate on determining the alcohol in a sample of liquid extract of cascara, the distillate, which contained 10 per cent. of alcohol, was shaken out with ether, to which the yellow color was communicated, leaving the aqueous layer colorless. On evaporating the ether a small quantity (0.003 Gm. from 25 Cc. of liquid extract) of residue was obtained, apparently consisting of a greasy, yellow body having an agreeable odor, and of minute slightly colored crystals. On the addition of ammonia a crimson-colored solution was obtained, which retained its color for many hours. Mr. Alcock suggests the possible identity of this substance with the yellow volatile body discovered by Tschirch and Klaverness in Uganda aloes in 1901.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 666.

*Rhamnus Carniolica—Adulterant or Substitute for Frangula Bark.*—John Moser, Jr., says that frangula frequently has admixed with it or is wholly substituted by the bark of *Rhamnus carniolica.* Of five samples of frangula recently examined by him only one was of official quality, three were mixtures of frangula and *Rhamnus carniolica* bark, and one consisted entirely of the latter. This bark is usually thicker than frangula bark, being 1 to 3 mm. thick; the external surface is grayish or grayish-brown, usually somewhat wrinkled longitudinally, and with numerous lenticels 1 to 2 mm. long, rather obscure; the inner surface is grayish to dark brown, longitudinally striate from the bast fibers near the surface; the fracture is short-fibrous, the bast fibers frequently projecting 0.5 to 1 Cm. from the inner bark; the inner surface is reddened by alkalies as in frangula; the odor is slight, and the taste bitter and astringent. In frangula the bark is thinner, darker brown, with more numerous, prominent, and larger lenticels; the inner surface is more finely striate, there are fewer bast fibers, and the medullary rays, which in *R. carnicola* are 4 to 7 cells wide, are in frangula only 2 cells wide, while the taste of frangula is only slightly bitter. —Amer. Journ. Pharm., Dec., 1909, 580.

**AQUIFOLIACEÆ.**

*Mâté—Improved Quality by Cultivation.*—G. Bertrand and T. Devuyst point out that improved methods in the cultivation of mâté have resulted in a product which gives an infusion of very agreeable taste and aroma, and quite transparent. The following analysis of the substance is given:
Water, determined at $110^\circ$ C., 10.5; matter soluble in ether, 16.57; organic matter soluble in water, 30.79; mineral matter soluble in water, 3.78; caffeine, 2.02; sugar, as glucose, 6.08; tannin, 11.22; organic matter insoluble in water, 52.73; mineral matter insoluble in water, 2.2; total nitrogen, 2.13; total ash, 5.98, all in percentage. Figures are also given for the analysis of the infusions obtained from 5 Gm. of the mate and 500 Cc. of boiling water. The first infusion was for three minutes at a temperature of about $90^\circ$ C., the second on the old marc for ten minutes, and the third for one hour. The results were, respectively: Total dissolved substance, 21.8, 10.0, 2.2; organic matter, 19.4, 9.4, 2.1; mineral matter (ash), 2.4, 0.6, 01; tannin, 7.68, 3.4, 0.05; caffeine, 1.39, 0.31, 0.26. The most agreeable "tea" is obtained by first pouring just sufficient boiling water onto the mate to moisten it thoroughly, and then, after a few minutes, adding the remainder of the boiling water and allowing to infuse for fifteen minutes.—Pharm. Journ. and Pharmacist, June 25, 1910, 787; from Bull. des Sci. Pharmacol., May, 1910, 249.

**Euphorbiaceae.**

**Caoutchouc—A New Solvent.**—Emil Fischer has patented in Germany the use of symmetrical ethylene dichloride (CIHC.CHCl) as a solvent for crude caoutchouc. The new solvent gives a true solution and not a mere swelling and diffusion of the material, and has the great advantage over most of the rubber solvents known of being non-inflammable. Its solvent action is greater than that of chloroform or of carbon tetrachloride. As its boiling-point is only $55^\circ$ C., it is also more volatile than other solvents, and its vapors are non-explosive.—Pharm. Ztg., liv (1909), No. 56, 552.

**Euphorbia Pilulifera—Preliminary Examination.**—In the course of a preliminary examination of *Euphorbia pilulifera*, J. Stableford Hill determined the amount of moisture in the drug to be 8 per cent., the ash 8.2 to 8.5 per cent. The details of his further experiments revealed the presence of a small quantity of alkaloid, tannic acid, a waxy substance, and several resins, but no volatile oil. Successive extractions of the drug with different solvents gave the following figures, calculated upon the dry drug: Petroleum ether, 1.67 per cent.; ether, 1.67 per cent.; chloroform, 0.58 per cent.; acetic ether, 2.66 per cent.; absolute alcohol, 11.15 per cent.—total, 17.73 per cent. Cold 90-per cent. alcohol alone yielded 12 per cent. of extractive, of which 56.3 per cent. was soluble in water.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 325-327.

**Hura Crepitans—Albuminoid Toxic Constituent.**—C. Richet states that the milky juice of *Hura crepitans*, the Brazilian euphorbiaceous plant, known to botanists by its curious fruit, contains an extremely poisonous substance of the nature of an albuminoid, which he has named

**Crepitin.** This is obtained by precipitating the juice with 95-per cent. alcohol. It is coagulated by acids and by heat. The minimum lethal dose,
by intravenous injection, for the dog, is 1 Mgm. for 100 kilos body weight. Death occurs after three days. Like abrin and ricin, it exerts its toxic action on the blood.—Pharm. Journ. and Pharmacist, May 7, 1910, 571; from Ann. Instit. Pasteur, 23, 745.

Jellas Root—Botanical Source (Probable) and Toxicity.—Specimens of jellas root, stated to be used, along with Antiaris toxicaria and Strychnos tieute, as an ingredient of “Ipoh,” the arrow poison used in the East Indian Archipelago, have been submitted by Mr. E. M. Holmes to Dr. Gordon Sharp to determine its toxicity. He finds that the bitter, dried weak-alcoholic extract gives no characteristic reactions with sulphuric or nitric acids, nor with sulphuric acid and potassium dichromate, and the same is true of the aqueous extract. Experiments on frogs show it to be a feeble poison, this action, manifested only with very large doses, pointing in the direction of methyl-strychnine or curare. A leaf of the plant and fruit attached, received with the root, was submitted to Mr. L. Brodie, who replied that “the structure of the leaf is of a peculiar type, and is so nearly identical with that of Euryeoma apiculatum, A. W. Benn., that the plant, at any rate, must be quite near to the genus Euryeoma (N. O. Euphorbiaceæ).”—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 80.

URTICACEÆ.

African Cannabis—Inferiority to Indian Cannabis.—E. M. Holmes calls attention to the importation during the last few years of a considerable quantity of “gauza” (Indian Hemp) from East Africa, and that he is quoted on the London drug market as authority for the statement that the African cannabis was as good as the Indian drug. Quite the contrary is true, however, since four years ago (see Proceedings, 1906, 798) he had pointed out that the African drug was not nearly as effective as the Indian, and had suggested that it should not be used for making the preparations of the B. P., though it might be useful for preparing corn solvents. The African leaves give a greener tincture and extract than the Indian, but this would not be a safe guide. Moreover the African drug varies very much in character, some containing much more stalks and leaves than others. The amount of alcoholic extract from a number of commercial samples recently examined by C. E. Sage varied from 6.2 to 10.8 per cent., which is much lower than that reported to Mr. Holmes in the paper above referred to.—Pharm. Journ. and Pharmacist, July 31, 1909, 132.

Bleekrodea Tonkinensis—A New Caoutchouc Tree in Tonquin.—Durand and Eberhard report the discovery of a new source of caoutchuc in a tree indigenous to Tonquin, Bleekrodea tonkinensis, growing abundantly in the province of Bao-Kan and in the southern sections of the provinces of Bao-Lac and Cao-Bang. The latex of this tree contains about 7 per cent. of caoutchouc, which is not inferior to the para drug.—Pharm. Ztg., liv (1909), No. 90, 891; from L’Union pharm., 1909, No. 10.
Figs—Components.—Paladino has determined the constituents in the pulp of fresh figs, which he reports as follows: water, 80 per cent.; nitrogenous bodies, 0.7 per cent.; fats, 0.3 per cent.; sugars, 16.2 per cent.; cellulose and seeds, 1.3 per cent.; ash, 0.7 per cent.; gum and mucilaginous matter, 0.8 per cent. The peel contained: water, 86.0 per cent.; nitrogenous bodies, none; fats, 0.1 per cent.; sugars, 5.4 per cent.; cellulose, 5.76 per cent.; gum, etc., 2.74 per cent. Dried figs contained: water, 57 per cent.; nitrogenous bodies, 41 per cent.; fats, 2.20 per cent.; sugars, 26.06 per cent.; cellulose, 8.0 per cent.; gum, 0.18 per cent.; ash, 2.52 per cent.—Pharm. Ztg., iv (1910), No. 30, 305; from Biochem. Ztschr., 1910, 263–265.

Spent Hops—Utilization as Cattle Food.—Clayton Beadle and Henry P. Stevens suggest the utilization of "spent hops" by subjecting them to the hydrolytic action of hydrochloric acid in a manner similar to that proposed by them (and patented) for the treatment of cotton seed hulls. The action of the acid is catalytical, none of it entering the composition of the food, though there is an actual waste of possibly 1 or 2 per cent. HCl on the weight of the product treated. After draining the spent hops, about 7 per cent. of material remains, which must be deprived of moisture, partly by hydraulic pressure and the remainder by heat, leaving, however, a little moisture before the addition of the acid, as the mass is more permeable in a semi-moist condition. The draining liquor was found to contain 8 to 10 per cent. of sugars, calculated on the weight of dried hops, which by drying down would form part of the food-stuffs. Some idea of the constituents of two samples after hydrolysis is gained from the following figures: Moisture, 9.16 and 10.51; ash, 6.08 and 6.89; hydrocycdulose, 33.62 and 26.52; fat, 6.39 and 10.71; protein, 19.35 and 21.30; carbohydrates, 25.4 and 24.07; food units (approx.), 89.8 and 104.1. Albuminoids in aqueous extract of the meal—2.05 per cent. No ill-effects have been observed from the use of this meal as food-stuff.—Chem. News, Oct. 22, 1909, 197.

Coniferae.

Turpentine—Acid Constituents.—According to the investigations of of Stanislaus Leskiewicz the oleo resins of Pinus silvestris and of P. martima contain an acid, sapinic acid, which is easily obtainable in a pure condition, but is readily changed in its rotatory power and action under the influence of heat. For this reason the acid, which is lèvorotatory when obtained from the turpentine itself at a temperature not exceeding 60° C., is much weaker in its rotatory action, and may even be dextro-rotatory, if obtained from the corresponding colophonium. By traces of hydrochloric acid, sapinic acid is converted into the acids of the sylvic series, of which at present only l-sylvic acid has been prepared. By distillation both this acid and sapinic acid are isomerized into the same
l-colophonic acid as that composing the crystallized acids found in rosin oil. All of these acids have a composition corresponding to the formula \( C_{20}H_{30}O_2 \).—Pharm. Ztg., iv (1910), No. 38, 386; from Journ. f. prakt. Chem., 1910, No. 8–9.

**Cypress Camphor—Identity with Cedar Camphor.**—In their Report for October, 1904, Schimmel & Co. stated that the only difference between cypress camphor with m. p. 87° to 87°C., and dextrorotatory cedar camphor was the optical inactivity of the former. At the same time they mentioned that, when subjected to the action of formic acid, cypress camphor yielded a dextrorotatory, and cedar camphor a laevorotatory, hydrocarbon. They now state that both these statements, so far as they relate to cypress camphor, require correction inasmuch as recently, on the occasion of working up a considerable quantity of material, it was shown that cypress camphor as well as cedar camphor is dextrorotatory, and, like the other, is converted into a laevorotatory hydrocarbon \( C_{15}H_{21} \) by dehydrating agents. The opt. rot. of this hydrocarbon was found to be—85° 57'. A solution of 2 Gm. cypress camphor (six times recrystallized) in 20 Cc. chloroform, gave \( [\alpha]_b + 2^\circ 1' \) in a 200 mm. tube. This works out at \( [\alpha]_b + 10^\circ 5' \). The value for cedar camphor observed at the time was \( [\alpha]_b + 9^\circ 31' \) (in 11.2 per cent. chloroform solution). Cedar camphor and cypress camphor must therefore be regarded as identical.—Schimmel’s Semi-An. Rep., April 1910, 46.

**CYCAEAE.**

*Macrozamia Spiralis*, Miq.—*A Reputed Cattle Poison.*—E. M. Holmes has received some seeds of *Macrozamia Spiralis*, Miq., forwarded to the Museum of the Pharmaceutical Society by Mr. L. G. Tweedy. These seeds are known in Queensland as the “Burrawong,” and are used by the natives as food, after prolonged washing, a kind of starch resembling arrow root being thus obtained. But some colonials who partook of a pie made from the seeds without washing them were all made ill. Mr. Tweedy states that if cattle eat the plant it causes partial paralysis of the hind-quarters, and causes the horns to grow in a coil over the face; but the cattle are not injured in any other way. They breed well, and the calves are unaffected, but the animals themselves deteriorate in value, as they cannot walk far. The plant grows 5 to 6 ft. high only, and is consequently in easy reach of the cattle. The stems yield a gum resembling tragacanth, but in small quantities only.—Pharm. Journ. and Pharmacist, Jan. 22, 79.

**B. Animal Drugs.**

**Leeches—Care and Preservation.**—Doering offers some practical suggestions based on a long experience in the care and preservation of leeches. He finds that a mixture of grass-roots, peat, clay and soil, properly
moistened, is the best material for their habitation, but points out the necessity also of feeding them occasionally, at specified intervals, to prevent them from starving and to keep them in vigorous health. Although it is commonly asserted that the leech can live without food for as long a period as 10 months, he considers it best to feed them at intervals of 6 months, establishing relays by keeping them in 2 separate compartments and changing them from one to the other every three months. In this way active leeches are always available in one of the compartments while in the other compartment the leeches are permitted to recuperate.

**Cantharides—Amount of Cantharidin in South African Species.**—W. C. Colledge reports the results of cantharadin determinations in six South African species of cantharides received from the government entomologist (Pretoria), employing a modified form of the method described by Self and Greenish (see Proceedings, 1907, 820). The results are given as follows:

*Mylabris oculata*, Thunb.—The beetle is 30 to 35 Mm. long; it is black with two broad light-yellow bands, and has two spots of the same color on the wing-cases. The powder is brown, and possesses a characteristic odor. Yield of cantharidin, 0.615 per cent.

*Mylabris holocericea*, Kley.—The beetle is about 13 Mm. long; the body and wing-cases are covered with fluffy hair, giving the whole a greenish appearance. The beetle has three yellow bands and two elongated spots on the wing-cases; the edges of the wing-cases are yellow. Yield of cantharidin, 1.3 per cent.

*Decatoma lunata*, Pallas.—The beetle is 20 Mm. long; it has fluffy hair on the thorax and on the wing-cases. The body has three wavy yellow bands. Field of cantharidin, 1.0 per cent.

*Eletica wahlbergia*, Fabr.—The beetle is 23 Mm. long, and has a very thin neck. The body, which is covered with short hairs, is black; the wing-cases are black, with a reddish-brown edge. The back of the head is reddish-brown. Yield of cantharidin, 0.32 per cent.

*Cantharis vellata.*—The body is about 20 Mm. long, and, like the wing-cases, it is covered with gray-colored hairs. Yield of cantharidin, 2.73 per cent.

*Lyttia coelestina.*—The body, which is bluish iridescent with greenish iridescent wing-cases, is 23 Mm. long. Yield of cantharidin, 1.89 per cent.

The author also mentions that specimens of the Chinese blister fly examined by the same process showed 1.2 per cent. of cantharidin.—Pharm. Journ. and Pharmacist, May 28, 1910, 674.

**Honey—Distinction of Natural and Artificial by the Content of Al-**
bumin Bodies.—R. Lund finds that true and artificial honey may be distinguished by their albuminoid content as follows: To 20 Cc. of a filtered 10 per cent. solution of the honey in a Barth's tube (such as is used for the determination of tannin in wine), 5 Cc. of 0.5 per cent. tannin solution are added and the volume of the liquid adjusted to 40 Cc. After 24 hours the volume of the precipitate produced is read on the scale of the tube. With artificial honey this amounts to only 0.03 Cc., whereas natural honey will show from 1.4 to 2.3 Cc.—Pharm. Zentralh. 50 (1909) No. 38, 799; from Ztschr. f. Unters. d. Nahr. u. Genussm. 17 (1909), 800.

Mel Despumatum—Injudicious Method of the G. P.—"Dr. B." regards it as a sine qua non that honey must not be boiled or evaporated if it is aimed to retain its delicate flavor and its constituents (particularly formic acid) intact. It should only be diluted. He has for some years conducted the process of purification, which he recommends for adoption in the G. P., as follows: The honey is stirred with one-half its weight of water and heated in a water-bath for several hours without any further addition whatever, or, better, alternately heated and cooled, because the substances causing turbidity conglobate better by the latter treatment than if continuously heated. The honey is then strained and adjusted to the proper specific gravity. In this way the honey is not absolutely bright, although clear in thin layers; but, what is more important, it retains the flavor perfectly, as well as all the formic acid originally present in the fresh honey.—Pharm. Ztg., lv (1910), No. 23, 232.

Beeswax—Adulteration with Ceresin.—Dr. C. Jacobsen reports as the result of an examination of 20 samples of white and yellow beeswax on the market that only two were found pure. All others were adulterated more or less, most frequently with ceresin, which was found in quantities up to 45 per cent.—Apoth. Ztg., xxv (1910), No. 14, 113.

Beeswax—Detection of Tallow.—A. Ostrogovich and S. Petrisor recommend the following method for the detection of tallow in beeswax: From 6 Gm. to 7 Gm. of zinc chloride is melted in a porcelain crucible, and then 1 Gm. of the wax is added. The crucible is covered with a lid, the under side of which has been wetted with two or three drops of a solution of 0.3 Gm. of phloroglucinol in 100 Cc. of concentrated sulphuric acid. The covered crucible is heated for thirty-five to forty seconds, and then the under side of the lid examined. If the sample of wax contained tallow the acrolein formed will have developed with the phloroglucinol reagent a reddish-violet color, which is intensified on addition of a few drops of alcohol. With pure wax only a faint brown coloration is produced. Very small quantities of acrolein produce only a yellow coloration.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 701; from Bull. Soc. Stiuite din Bucuresti, 18 (1909), 127, through Journ. Soc. Chem. Indus.

Beeswax—A Practical Mold.—H. G. Posey constructs cheaply and
practically a mold for making different sized cakes of yellow wax by screwing the required number and sizes of seamless tin ointment boxes on a board, as shown by Fig. 62, a hole being first punched into the boxes to admit a properly-fitting screw.—Bull. Pharm., Jan., 1910, 29.

Klipzweet and Hyraceum—Two Curious South African Products.—J. Parry describes a curious South African remedial agent known by the Dutch farmers of the Cape Colony by the name of "klipzweet," which literally means "rock sweat." It is found gradually oozing out of chinks in the rocks or accumulating on the rock surface, or flowing over them until it hangs down like a fringe of pitch, and bears in general some resemblance to another curious South African product, "hyraceum," resembling castoreum, which has long been known and used medicinally in the Cape Colony. Quoting indiscriminately from a companion paper, by W. Fröembling, "klipzweet," when fresh, is black and sticky, extract-like, of not a disagreeable odor, and forms a more or less acid solution with water. Warmed in a test-tube, it melts easily, emitting faintly aromatic, colorless fumes, these getting later, when the heat is increased by direct flame, acrid, and at last, when incineration starts, smelling like burnt horn or hair. Further preliminary examination revealed the presence of a sweet substance resembling honey, besides a more or less wax-like fat, together with a fair amount of organic substance of vegetable or animal origin. The microscopic examination, both by Mr. Fröembling and Mr. Peringuey, a local authority, reveals the presence of pollen grains, particles of vegetable tissues, insects, or rather partly dismembered bodies of these, among which there was an abundance possessing bee-like features. In short, it seems highly probable that the so-called "klipzweet" is a product of some species of bee, much smaller than the ordinary Cape bee, to which the name _Apis pygmaea_ may be appropriate. The exudation is made up of wax, honey, waste products of a hive, including dead insects and their parasites, as well as other secreta and excreta. The mineral matter in minute particles is partly dust, wiped from the wings and bodies of the insects, partly scraped from the rock with the adhering "klipzweet" by collectors. This substance is therefore quite distinct from

_Hyraceum_, which consists of the excreta of the rock-rabbit (_Hyrax capensis_), and constitutes its principal adulterant and substitute. Mr. Parry has obtained authentic samples of both hyraceum and "klipzweet" and gives the results of a comparative examination.—Pharm. Journ. and Pharmacist, Nov. 20, 1909, 632–633.

_Silajit and Klipzweet—Allied Substances._—The publication of the pre
ceeding papers of Mr. Parry and Dr. Froembling prompts David Hooper to call attention to a paper on "Silajit: An Ancient Eastern Medicine," which he communicated to the Asiatic Society of Bengal in 1903 (see Proceedings, 1904, 647), and now gives some further details suitable to follow the descriptions of klipzweet. In the first place, the names have identically the same meaning. Silajit or silajatu is derived from sila = a stone, and jatu = produce or essence; hence it may be regarded as a substance born of the rock, essence of stone, or literally "rock sweat." The localities in which this article is reported to be found are confined to Northern India. It is obtained from the lower, central, and upper range of the Himalayas, and in the Vindhyan Hills, and is procurable in Simla, Mussoorie, and Katmandu. Mr. Hooper describes three kinds of silajit met with in India, namely, white, black, and cream-colored. White silajit is of a mineral nature and is more or less pure aluminum sulphate. It is obtained from Nepal. Black silajit is quite a different article. As sold in the bazaars of Calcutta it is in form of dark brown or black cakes, tough and pasty in consistence, and has an odor resembling that of leather. Cream-colored silajit, received from Jeypur and Baluchistan, consists of crystalline compounds, and has a strong nauseous odor. It is evidently of animal origin, since various samples yielded from 54 to 64 per cent. of urea, and therefore probably consists of crude urea, or inspissated urine. Mr. Hooper has also received samples of silajit from Baluchistan under the names of khatmolt (rock smoke), maskana churro (hill juice), maulai and mumiai, found in inaccessible places in the Jalai and Tao Hills. But whatever this drug may be, it forms a favorite medicine with Hindu physicians. Indeed, the author of "Charaka" says that there is no curable disease which will not yield to "silajatu" in judicious combination with other drugs.—Pharm. Journ. and Pharmacist, Jan. 8, 1910, 24.

Cod Liver Oil—Suggestion for Storage.—F. M. Apple directs attention to a simple and inexpensive method of the storage of cod liver oil, whereby the sweet natural odor of the oil is preserved and the tendency for it to acquire a fishy odor and taste is prevented. He uses for this purpose half-pint and pint bottles which formerly contained proprietary preparations, cleaning them thoroughly and sterilizing them before use. These are filled in sufficient number to completely exhaust the original contained when first opened, and, being then well corked with a good sound cork are set aside in a cool dark part of the cellar, to be drawn upon one at a time as demand arises.—Apothecary, March, 1910, 22.

Dried Egg Yolk—Spurious Commercial Sort.—Bordas and Tonplain state that granulated and dried yolk of egg is now largely produced, and has a wide application. This has led to the appearance of fraudulent substitutes, which are nothing but casein colored with yellow aniline colors. The genuine egg yolk yields over 50 per cent. of fat to extraction with ether, and contains 14 per cent. of substances soluble in 95 per cent.
alcohol. The fictitious articles only yield relatively small quantities of soluble matter with both these solvents.—Pharm. Journ. and Pharmacist, April 9, 1910, 455; from R ép. de Pharm., 22 (1910), 115.

INORGANIC CHEMISTRY.

GENERAL SUBJECTS.

U. S. P. Chemicals—Manufacture and Official Tests for Them.—George D. Rosengarten, referring to the decided change in conditions surrounding the manufacture of U. S. P. chemicals, brought about by the legalization of the U. S. P. as a standard, says that while the manufacturers have always desired to attain the highest purity for their product, it was not practicable in many instances to comply with the U. S. P. requirements until the "Corrections and Additions" to the Pharmacopoeia were promulgated (in 1907), which has made compliance possible, with some few exceptions, in so far as chemicals are concerned. There is, however, still ample scope for revision, and the directions in which this needs to be accomplished by the study of all the subjects relative to the U. S. P. and medicinal chemicals in particular is admirably pointed out and discussed in his paper on the "Manufacture of U. S. P. Chemicals and Criticisms of U. S. P. Tests for the Same," read at the November meeting (1909) before the Scientific Section of the Philadelphia Branch of the A. Ph. A., which is published in Amer. Journ. Pharm., Jan., 1910, 27-32.

The Purity Rubric and Tests of the U. S. P.—Necessity for Quantitative Methods.—Atherton Seidell and M. I. Wilbert, discussing the purity rubric and the tests of the U. S. P. VIII, direct attention to the importance of an accurate description of the tests—qualitatively and quantitatively—for determining the purity of medicaments within the requirements of the purity rubric established as the standard. As a practical demonstration of the possibility of elaborating efficient yet simple quantitative methods, the authors communicate a number of laboratory notes on some of the pharmacopœial compounds examined in the Division of Pharmacology of the Hygienic Laboratory (U. S., P. H. & M. H. Service), in a paper read in the Division of Pharmaceutical Chemistry of the American Chemical Society, Dec., 1909, which is published in the Amer. Journ. Pharm., Feb., 1910, 63-68.

Quantitative Tests of the U. S. P. VIII.—Frank X. Moerk has worked out a practical classification of the quantitative tests of the U. S. P. VIII, in which all of the quantitative determinations based on similar methods are grouped together, so that it will not be a very difficult matter to formulate methods applicable to entire groups. The numerous tables in this
very comprehensive work are elucidated by comments applying to the special methods involved. The paper covers 21 pages of the "Proceedings," 1909 (from p. 919–939).

Exsiccated Salts of the U. S. P.—Precaution in Keeping.—Chas. H. LaWall, purchasing samples of exsiccated salts with the object of determining the amount of moisture, if any, contained in them, found that it was exceedingly difficult to obtain U. S. P. exsiccated salts, and that in most cases salts known as "dried and powdered" were substituted without anything being said to the purchaser. His experiments showed the following percentages of moisture in salts supplied as exsiccated: Sodium Carbonate, 4.01 per cent; Sodium Phosphate, 17.70 per cent; Sodium Sulphate, 4.10 per cent.; Ferrous Sulphate, 2.15 per cent.; Exsiccated Alum, 9.9 per cent. In further experiment, these salts were made perfectly anhydrous and then exposed to determine the amount of moisture absorbed during a certain period. This proved to be considerable, and the author therefore proves, (1) the necessity of the pharmacist investigating his exsiccated salts when purchasing them, and (2) the necessity of preserving them when right in moisture-proof containers.—Proc. Penna. Pharm. Assoc., 1909, 369–371.

Oxygen.

Ozone—Question of Formation of Ultra-violet Light—Bordier and Nogier have stated that ozone is not formed by the ultra-violet light of a quartz lamp, and they say that the smell observed in the neighborhood of a burning quartz mercury lamp is not due to ozone, but to the effect of free electric discharges upon the olfactory nerves. Franz Fischer has how, however, actually condensed the ozone by means of liquid air, and has identified it by the violet coloration it produces on tetra methyl base papers as well as by its characteristic smell. He has also determined it quantitatively by leading it through potassium iodide solution and then titrating.—Chem. News, Aug. 27, 1909, 107; from Ber. d. D. Chem. Ges., 42 (1909), No. 10.

Ozone—Luminosity.—M. Beyer finds that phosphorescent luminosity in the dark is imparted to ozonized oxygen if it is heated to a temperature of about 350° C. The author regards this phenomenon as being evidently due to energy liberated by the conversion of the ozone, manifesting itself partly as light. He concludes that it is probable that in all transformations of true peroxides, favorable conditions for the manipulation of light are produced; so, for example, also in the luminosity of phosphorus and by the photochemical activity of hydrogen dioxide.—Pharm. Ztg., lv (1910), No. 29, 291; from N. Chem. Zentral-Bl., 1910, No. 9.

Hydrogen.

Hydrogen—Industrial Production.—Discussing the various methods in
use for the production of hydrogen for aerial navigation, Professor H. Strache, after mentioning the well-known methods of the electrolytic decomposition of water and by the reaction of sulphuric acid and iron as being unsuited for the economic production of the gas in quantities, calls attention to the method of hydrogen production by the decomposition of water vapor with iron at a red heat, which has long been employed in Berlin by the division of Military Aeronautics. The method, however, consumes great quantities of iron, and has therefore been economically improved by regenerating the metallic iron from the ferric oxide produced by subjecting the latter to the action of a current of hot generator gas. This method has since been modified, by conducting the process in close retorts and effecting the reduction by means of water gas. Other methods which have been economically and successfully used for the industrial production of hydrogen, depend on the decomposition of slaked lime by iron: Ca(OH)$_2$ + Fe $\rightarrow$ CaO + Fe$_2$O + H$_2$; or, by means of carbon: Ca OH$_2$ + C + H$_2$O $\rightarrow$ CaCO$_3$ + 2H$_2$. Furthermore, a perfectly pure hydrogen (100 per cent.) is obtained by a new method, which depends on the ability of potash-lime to absorb water gas (composed of carbon oxide and hydrogen) at 180° C., and to part with pure hydrogen when the heat is increased to 300° C. This method is particularly adapted for the production of hydrogen in the field, for which purpose at present the decomposition of sodium hydroxide by silicon (Si + 4Na(OH) = Na$_2$SiO$_4$ + 2H$_2$) is employed, because of the easy transportation of the material—the principal objection to the latter being the inconvenient frothing of the soda lye. Pharm. Ztg., lv (1910), No. 19, 190; from Oesterr. Chem. Ztg., 1910, No. 4.

**Hydrogen—Action in Nascent and Dry Condition.**—It is found by A. C. Vouonasos that perfectly dry hydrogen in the nascent condition will combine with many elements and compounds with which, under ordinary conditions, it will not unite. Hydrogen is obtained in this state by heating anhydrous sodium formate to 400° C. The substance under experiment is mixed with the salt, and the mixture heated in an atmosphere of dry hydrogen. Under these conditions amorphous phosphorus gives pure phosphoretted hydrogen; sulphur forms hydrogen sulphide; arsenium, arsenuretted hydrogen; antimony gives a little antimonuretted hydrogen when antimonite is heated with sodium formate. Silicon does not react, but its salts give a little hydrogen silicide. Boric anhydride heated in an iron tube with metallic sodium and sodium formate gives a little gas which is probably hydrogen boride. Nitrites thus treated give ammonia; cyanides, hydrocyanic acid; and alkali carbides, acetylene.—Pharm. Journ. and Pharmacist, Mar. 26, 1910, 398; from Compt. rend., 150 (1910), 465.

**Water—Decomposition by Ultra Violet Rays.**—Kernbaum having noted the formation of H$_2$O$_2$ when water is submitted to the action of radium
β-rays, now finds that ultra violet rays have the same effect. Courmont and Nogier had previously observed that water becomes sterile when exposed to ultra violet rays. According to Kernbaum's experiments, when 15 Cc. of distilled water were exposed to these rays from a Heracus lamp for 200 hours, 26 Cc. of gas was liberated, which proved to be hydrogen, and the water contained H₂O₂. The decomposition, however, does not appear to be continuous; it ceases after attaining a maximum, and no gas appeared to be formed during the last thirty-five hours of the exposure. The reaction may be expressed by the equation, 2H₂O = H₂O₂ + H₂. These results accord with the facts published in 1874 by Schöne, who demonstrated that hydrogen peroxide occurs in rain and snow water, and that greater quantities are present during the day than at night, and that none is found in dew.—Pharm. Journ. and Pharmacist, Sept. 4, 1909, 319; from Compt. rend., 149 (1909), 273.

Drinking Water—Sterilization by Light.—The practical application of the bactericidal action of the light of mercury-vapor quartz lamps to sterilizing drinking water has been carried out at Lyons by Nogier. It is proved that rays of short wave length possess a bactericidal action on water within a radius of 30 Cm. from the source of light, at which distance pathogenic microbes are destroyed by one minute's exposure. The effect is more marked when the lamp is immersed in the water. Complete sterilization in one to two minutes of about 26 gallons of water contaminated with colons and typhoid bacilli was obtained by immersing the lamp in the tank. Water thus sterilized has no action on the development of aquatic plants and animals; its chemical constituents and salts are unchanged; and it keeps sweet well. The presence of colloid matter in the water hinders the process of sterilization. Thus, in the presence of peptone solution, sterilization was not achieved after ten times the length of exposure. The author denies that oxidation has anything to do with the sterilization of water; it is to be attributed solely to the action of light.—Pharm. Journ. and Pharmacist, April 16, 1910, 482; from Archives d'Electricité Médicale, 10 (1910), 1, through Brit. Med. Journ., 1910, 1, 403.

Sterilization of Water—Experiments by Means of Violet Rays.—Continued investigation by Billon Daguerre shows that the mercury lamp is neither the most economical nor the most efficient source of ultra-violet rays for sterilizing water. The radiant energy derived from the passage of an induction current from a small Ruhmkorff coil giving a spark of 15 Mm., through rarified hydrogen in a quartz tube, gives off ultra-violet rays in such quantity and of such high bactericidal power as to completely sterilize 5 liters of polluted Seine water per minute. The water used was inoculated with Bacillus coli culture; before exposure to the rays it showed 29,000 colonies per mil. After one minute's exposure, cultivation failed to show a single colony. No rise of temperature takes place by
this method, and the bulk of the energy used is given off as bactericidal ultra-violet rays. With the mercury-lamp, on the contrary, not more than 20 per cent. of the total energy used is given off in this form.—Pharm. Journ. and Pharmacist, March 26, 1910, 398; from Compt. rend., 150 (1910), 479.

Sterilization of Water with Ozone—Avoidance of Metals in the Production of Ozone.—Ed. Bonjeau has observed that in large installations for ozonizing air appreciable amounts of oxides of nitrogen are formed, and he has succeeded in determining the successive stages of their formation. Ferric oxide is first formed without nitrification. The oxide thus formed in the finely divided state favors the production of nitrous vapors, which are then transformed into nitric acid, and attack the lead or iron of the ozonizers. Hence the use of these metals should be altogether avoided. —Chem. News, Sept. 24, 1909, 160; from Compt. rend. 148 (1909), No. 26.

Distilled Water—Presence of Copper.—Attention is directed by a writer in "Pharm. Ztg." to the fact that the distilled water supplied by Mineral Water manufacturers (in Germany invariably) contains traces of copper. These distillates will pass muster on all the requirements and tests of the Germ. Pharmacopoeia: but if five or ten liters of the water are percolated slowly drop by drop through a cotton filter moderately compacted in the tubular of a large funnel, the cotton acquires a lively green color, and readily gives the copper reaction with H₂S or with potassium ferrocyanide.—Pharm. Ztg., liv (1909), No. 67, 651.

Commercial Distilled Water—Oxidizing Action.—L. Tixier finds that ordinary distilled water, although answering all the requirements of the French Pharmacopoeia, exerts distinct properties of an indirect oxydase. It gives a blue reaction with fresh tincture of guaiac and acetic solution of benzidine in presence of hydrogen peroxide, and reacts with Meyer’s phenolphthalein reagents. It loses this property when redistilled from a glass retort. It is, therefore, supposed that its oxidizing reactions are due to extremely minute traces of copper derived from the distilling plant, although the amount of the metal present is not sufficient to give reactions by ordinary tests. Mineral waters, well, river, and tap-water do not give these reactions.—Pharm. Journ. and Pharmacists, May 21, 1910, 645; from épért. de Pharm. 22 (1910), 160.

Peroxide of Hydrogen—Preservation with Acetanilide.—A. R. L. Dohme and H. Engelhardt have examined a number of samples of peroxide of hydrogen from different manufacturers which had been preserved with acetanilide, and in most cases found that the preparation smelled strongly of nitrobenzene, showing that a decomposition had taken place. The authors conclude that on this ground the use of acetanilide as a preservative for peroxide of hydrogen is unsuitable, the recent claim to the con-
Other preservatives that have been proposed are boric acid, sodium chloride, magnesium chloride, or calcium chloride, and free acids—the latter being, in the opinion of the author, the most suitable if it should be decided that acentanilide is unsuitable. They strongly recommend the use of an excess of either sulphuric or phosphoric acid, inasmuch as these two acids are not likely to be acted on by the peroxide, and the amount of free acid should be increased to about twice the amount at present permitted in the Pharmacopoeia.—Amer. Journ. Pharm., Feb., 1910, 69–71.

Hydrogen Dioxide—New Colorimetric Test.—Denigès points out that an entire series of phenol-like bodies—such as phenol, resorcinol, pyrogallol, etc.—give with hydrogen dioxide and sulphuric acid more or less intense color reactions. A very distinct and characteristic reaction, which he regards as being available for the detection of H₂O₂ is obtained with guaiacol. If 0.3 Cc. of a 5 per cent. alcoholic solution of guaiacol is added to 2 Cc. of concentrated sulphuric acid containing a single drop of 10 per cent. H₂O₂ solution, a handsome blue-green color is produced. If quinine is used in this test, in place of guaiacol, an intense yellow color is produced.—Pharm. Ztg., liv (1909), No. 68, 662; from Journ. de Pharm. d'Anvers.

Hydrogen Dioxide—Cobalt Naphthenate a Sensitive Reagent.—K. Charitschkoff has observed that the rose-red solution of cobalt naphthenate is changed to dark-brown or olive-green in the presence of hydrogen dioxide and recommends this reaction as a sensitive and characteristic test for the latter. A strip of filter paper is saturated with the solution of the cobalt salt in benzin, and the rose-red paper resulting after drying is moistened with the liquid to be tested, whereupon it immediately assumes an olive-green color, distinctly visible in dilutions of 0.03 per cent. H₂O₂. The reagent paper is not affected by the direct action of ozone.—Pharm. Ztg. lv (1910), No. 8, 78; from Chem. Ztg., 1910, No. 7.

HALOGENS.

Bromine—Rapid Titration of its Solutions.—M. Mausier says that bromine may be estimated by its action on sodium formate, but the hydrobromic acid which is formed checks the reaction, and makes it too slow to be used as a test. This may be obviated by the presence of zinc oxide, which exercises no influence on the reaction except by neutralizing the acid. The method of procedure is as follows: Solution of sodium formate of a strength of 1.6125 Gm. per liter is prepared; this will be decomposed by an exactly equal volume of 3 per-cent. bromine water. Ten Cc. of this solution is placed in a flask of about 60 Cc. capacity, 0.1 Gm. of precipitated zinc oxide is added, and the bromine solution is then gradually run in with frequent shaking; a yellow tint lasting for one minute shows the end of the reaction. The amount of bromine mechanically
fixed by the zinc oxide and necessary to color the liquid is 0.018 Gm.; the volume of bromine solution used contains, therefore, 0.318 Gm. of bromine, from which its percentage strength can be calculated.—Pharm. Journ. and Pharmacist, January 1, 1910, 7; from Rép. de Pharm., Oct. 10, 1909, 437.

Chlorine—Preparation by Means of Ammonium Persulphate.—C. Matignon and R. Trannoy state that ammonium persulphate reacts in the cold with a solution of hydrochloric acid, giving a very regular stream of chlorine. A good yield is thus obtained, and the reaction may be utilized for the preparation of the gas. It suffices to run the acid onto the salt placed in a suitable flask fitted up for the purpose, to obtain after a few moments a constant current of the gas during the greater part of the reaction. No oxygen compounds of chlorine are produced.—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 81; from Bull. Commers., Nov., 1909, 527.

Chlorinated Lime—Estimation of Alkalinity in its Solutions.—K. J. P. Orton and W. J. Jones give the following directions for estimating the alkalinity of bleaching powder solutions: A known volume of approximately $\frac{N}{10}$ hydrochloric acid is placed in a Drechsel bubbler, and then a given volume of the bleaching powder solution is run in. A fairly rapid current of air, freed from dust, is now drawn through the liquid, the bubbler being carefully shielded from light. Aspiration for three-quarters of an hour suffices to free the liquid from chlorine (as shown by adding one drop of a 0.1 per cent. solution of methyl orange, which is bleached if any chlorine remain). The excess of acid is then titrated with $\frac{N}{10}$ sodium carbonate. In the case of solid basic hypochlorite (or compounds of calcium chloride and hypochlorite) the procedure is identical, except that it is more convenient to introduce the solid into the bubbler before the acid. The alkalinity of the solutions or solid is calculated from the following equations: $\text{Ca(ClO)}_2 + 4\text{HCl} = \text{CaCl}_2 + 2\text{H}_2\text{O} + 2\text{Cl}_2$; and $\text{Ca(OH)}_2 + 2\text{HCl} = \text{CaCl}_2 + 2\text{H}_2\text{O}$. The thiosulphate or arsenite titre $\frac{N}{10}$ of the bleaching solution gives directly the volume of $\frac{N}{10}$ hydrochloric acid reacting with the hypochlorite. It is necessary that no hypochlorous acid must pass over during the aspiration; it must entirely react with the hydrochloric acid. All the chlorine must be evolved as gas, and none reduced to hydrochloric acid. The hydrochloric acid must not react with chlorate at the dilutions used, and at the ordinary temperature.—Pharm. Journ. and Pharmacist, July, 24, 1909, 105; from Analyst, July 1909, 317.

Chlorinated Lime—Inferiority on the German Market.—C. Jacobsen directs attention to the inferior quality of chlorinated lime supplied in Germany. On account of its cheapness, this product is largely used as a disinfectant, though it is produced in enormous quantities as a bleaching agent in various technical processes, being now made at a trifling cost.
electrolytically in connection with caustic alkali manufacture. The author says that on the small scale a product containing 40 to 43 per cent. of available chlorine can be obtained, but the technical product contains 35 to 36 per cent.; the German Pharmacopœia, however, requires only 25 per cent. Examination of commercial specimens shows that most of them are much below even that moderate strength. Twelve samples were obtained in Jena from dealers of various kinds; two of these contained respectively only 0.6 and 1.0 per cent. of available chlorine, and consisted of chalk with a small admixture of chlorinated lime. Other samples contained from 3.1 up to 18.7 per cent., and only one out of the twelve contained over 20 per cent.; this one gave 29.5 per cent. as the mean of four analyses, and it was obtained from an apothecary. The author's observations point out the importance of frequent examinations of this product, which in cases of epidemic might prove useless as a disinfectant unless of a reasonably proper strength.—Apoth. Ztg., xxiv (1909), No. 94, 893.

Iodine—Determination in Albumin Compounds.—Fendler, Frank and Stüber find that the decomposition of organic matter necessary in estimations of iodine in its compounds with albumen, for example, iodilin, is not difficult if not more than 0.5 Gm. of the substance is taken in operation. The substance is slowly heated with 2 Cc. of fuming nitric acid in a closed tube, at first for one hour to 100° C., then one hour to 150° C., and finally during six hours to 175° C.—Pharm. Ztg., lv (1910), No. 38, 385; from Ztschr. f. Unters. d. Nahr.-u. Genussm., 1910, No. 7.

Potassium Iodide—Non-occurrence of Iodate in the Commercial Salt.—The prevailing opinion, confirmed by the official tests of the pharmacopœias, that potassium iodate is a frequent impurity in commercial potassium iodide, is stated by L. W. Andrews to be a fallacy. The production of a blue color when a solution of the iodide is treated with hydrochloric acid and starch is by no means conclusive evidence of this impurity. A positive reaction will be afforded by this test in the presence of minute traces of iron or of copper, and these metals frequently occur as impurities in potassium iodide. The only reliable test for iodate is obtained when potassium acid tartrate (or tartaric acid, as in the B. P. test) is used as the acidifying medium, air being excluded. As a rule commercial potassium iodide does not contain more than 20 parts of iodate in 1,000,000 of iodide.—Pharm. Journ. and Pharmacist, Oct. 16, 1909, 474; from Journ. Amer. Chem. Soc., 31 (1909), 1055.

Hydrofluoric Acid.—Detection in the Presence of Fluorides.—W. Cronheim recommends the following method for the detection of hydrofluoric acid in the presence of fluorides, which is available in dilutions up to 1 :800,000 in fruit juices or aqueous solution. The fluid under examination is mixed with a large excess of 95 per cent. alcohol which precipitates the fluorides quantitatively, while hydrofluoric acid remains in solution—prob-
ably also organic fluorine compounds. This operation is facilitated by
the addition, also in excess of ether. The precipitate is allowed to settle
in the cold, the liquid filtered after standing one hour, and rendered alka-
line with lime or baryta water. After several hour's subsidence the pre-
cipitated calcium or barium fluoride is collected on a filter, incinerated,
and the ash is tested by the usual corrosion method for hydrofluoric acid.
145.

HELIUM.

Helium—Occurrence in the Gases from German Potash Beds.—Ernst
Erdmann has collected and analyzed a specimen of the combustible gases
generated from the carnalite of the Leopoldshall Salt Mines, and found
them to consist of—hydrogen, 83.6 methane, 4.4; residue, 12.0 per cent.
by volume. The residue contains considerable quantities of helium and
some neon. It has been suggested that the iron chloride present in the
rocks decomposes the water of crystallization of the carnallite, setting
hydrogen free, while the oxygen oxidizes the iron salt to haematite. The
author has found no experimental confirmation for this assumption, but
suggests that radium salts were originally present in the salt deposits, and
that by the action of their emanation on water hydrogen was set free and
helium and some neon formed. This theory is confirmed by the occur-
rence of blue rock salt, the color of which is due to the action of radium
rays on sodium.—Pharm. News, May 27, 1910, 251; from Ber. d. D.
Chem. Ges., 43 (1910), No. 5.

SULPHUR.

Sulphur.—Commercial Quality.—Of five samples of sulphurated
lime assayed by P. M. Davis only one contained as much as 55 per cent.
of calcium sulphide. The author had no difficulty to prepare a satisfac-
tory product when C. P. calcium sulphate was used, but experienced great
difficulty to prepare such from the commercial sulphate.—Amer. Journ.

Sulphites—Effect when used as a Preservative.—As a result of experi-
ments by K. B. Lehmann and A. Trentlein on cats and dogs it would
appear that the prolonged ingestion of minute quantities of sulphites is
followed by no appreciable disturbance of the health. Doses of sodium
sulphite, ranging from 15 to 62 Mgm. per kilo body weight, continued
daily for 200 days, had no apparent effect, and did not cause the faintest
indication of renal lesion. The animal organism can, therefore, oxidize
such amounts of sulphites without harm. The use of sulphites should not,
however, be permitted, in the author's opinion, since their use disguises
the appearance of incipient decomposition and allows inferior materials
to be used in the preparation of dietetic articles.—Pharm. Journ. and

Anhydrous Sodium Sulphite—A Substitute for the Hydrated Salt now Official.—Although the U. S. P. requires that sodium sulphite (Na₂SO₃·7H₂O) should contain not less than 94 per cent. of this salt, it is the experience in the Hygienic Laboratory that the commercial salt contains as much sulphate as it does sulphite. Elias Elvove mentions a sample recently analyzed that consisted of 22.05 per cent. sodium sulphite, 25.00 per cent. sodium sulphate, and 52.50 per cent. of water, while a sample of the salt (Na₂SO₃·7H₂O) prepared in the Hygienic Laboratory, and showing a purity of 99.69 per cent. immediately after preparation, was found to have lost approximately one-fifth of the total available sulphite after standing six months in a glass-stoppered bottle, under ordinary conditions, and others have had a similar experience. On the other hand, anhydrous sodium sulphite, as pointed out by Hartley and Barrett, possesses stability so long as it is kept dry. A sample of anhydrous salt, obtained from the same wholesale firm from which the unsatisfactory sample of hydrated salt was obtained, assayed 96.5 per cent. pure Na₂SO₃, and even the poorest sample examined assayed over 91 per cent. Furthermore, direct experiments made with seven samples of anhydrous salt, ranging when received from 91.25 to 99.00 per cent. pure Na₂SO₃, showed on the average a loss of not more than 1 per cent. after being kept for 221 days, under ordinary conditions, in glass-stoppered bottles. The author therefore recommends that the hydrous sodium sulphite at present official in the U. S. P. be replaced by the anhydrous salt in the revised Pharmacopoeia.—Amer. Journ. Pharm., May, 1910, 211-218.

Sodium Sulphite—Detection in Presence of Sulphate and Thiosulphate.—F. H. Weston suggests the following method for the detection of sodium sulphite in the presence of sulphate and thiosulphate: Prepare a solution of the substance in water of about 5 per cent. strength. To 5 Cc. of this solution add a solution of iodine in potassium iodide (\(\frac{8}{10}\) iodine is most convenient); if decolorized continue till faint trace of iodine is obtained (presence of sulphite or thiosulphate or both); test this solution as to acidity, and if found to be acid the probable existence of a sulphite is indicated. To another 5 Cc. of the original solution add half the quantity of iodine solution as used in the first test, shake well, and test for sulphur dioxide by smell and by adding dilute potassium dichromate solution drop by drop. If pale green coloration is produced, sulphur dioxide is present, and hence a sulphite. If no coloration, then a thiosulphate is present. The sulphate can be detected by the barium chloride test, and the thiosulphate confirmed by the usual tests even in the presence of sulphite.—Chem. News. Oct. 8, 1909, 176.

Sulphates—Volumetric Estimation.—A. D. Mitchell and C. Smith rec-
ommend the following volumetric method for the estimation of sulphates as being rapid and accurate: A convenient quantity of the sulphate is dissolved in water or pure hydrochloric acid (or, if necessary, dilute nitric acid) and a slight excess of standard $\frac{2}{5}$ solution of barium chloride is added. After boiling, the mixture is rendered neutral by adding ammonium hydroxide; sodium acetate, acetic acid, and a slight excess of decinormal ammonium dichromate solution are added. The mixture is made up to 100 Cc., and 25 Cc. of the clear supernatant liquid is removed after the precipitate has settled, and titrated with vigintinormal ferrous-ammonium sulphate, using potassium ferricyanide as indicator. The first appearance of a green tinge is taken as the end-point. The method has been applied to ammonium, sodium, potassium, zinc, magnesium, and copper-ammonium sulphates, giving results accurate to about 0.2 per cent. In the case of potassium sulphate considerable absorption occurs (nearly 2 per cent.) which is minimized by boiling the precipitate for several hours with a little dilute hydrochloric acid, neutralizing with ammonium hydroxide, and proceeding as before. With copper-ammonium sulphate a well-defined end-point, at which a green tinge affects the predominating brown color of copper ferricyanide, can be found by practice. Excluding weighings, the authors state that five determinations can be made in an hour.—Chem. & Drugg. Jan. 15, 1910, 77; from Trans. Chem. Soc. Dec. 1909, 2193.

SELENIUM.

Selenium—Transformations.—According to the studies of Maurice Coste, selenium can exist at the ordinary temperature in three states: (1) Precipitated or vitreous selenium; (2) red crystallized selenium; (3) black metallic selenium. These three varieties are characterized by different densities. Metallic selenium dissolves easily in several solvents, e.g., carbon disulphide, toluene, etc., and when a solution is rapidly cooled, red selenium is obtained. Vitreous selenium gives red crystallized selenium in presence of quinoline and of aniline. Vitreous selenium is transformed into metallic selenium at 98° C.; the author has studied the transformation by means of a dilatometer, and finds that in toluene it is completed in an hour. The density after the transformation = 4.62. (Density of vitreous selenium = 4.30.)—Chem. News, Dec. 24, 1909, 316; from Compt. rend., 149 (1909), No. 17.

Selenophosphates—Preparation and Properties.—Fritz Ephraim and Etta Majler have prepared selenophosphates of the alkalies, alkaline earths and magnesium by the action of phosphorus pentaselenide on the selenides of the metals, $3R_2Se + P_2Se_5 = 2R_2PSe_4$. The tetraseelenophosphates were never obtained thus in the solid state, but they were gradually decomposed by the water, some of the selenium being replaced by oxygen according to the equations $R_2PSe_4 + H_2O = R_2PSe_3O + H_2Se$ or $R_2PSe_4 + 2H_2O = \ldots$
Intermediate products of formula $R_3PSe_{4-n}O_n$ frequently resulted, and possibly compounds were formed which could yield an isomorphous mixture. The oxyselenides are also formed from metallic hydroxide and phosphorus selenide. In spite of excess of alkali the tertiary salts often hydrolyze to form secondary salts. They decompose in water, especially on warming, according to the equation $R_3PSe_4 + 4H_2O = R_3PO_4 + 4H_2Se$. The mother liquors oxidize very readily in air, turning red with separation of selenium, but the dry salts are much more stable. When the mother liquor is completely removed they appear greenish-yellow. The selenophosphates of the alkalies are more easily prepared than those of the alkaline earths; only the secondary salts of the latter
have been obtained. The properties of strontium selenophosphate are intermediate between those of the analogous barium and calcium salts.—Chem. News, April 8, 1910, 166 ; from Ber. d. D. Chem. Ges., 43 (1910), No. 2.

NITROGEN.

Nitrogen—Estimation with a Modified Apparatus by the Kjeldahl Process.—In distilling off the NH₃ in a Kjeldahl estimation, F. E. Weston and H. R. Ellis employed the modified apparatus shown by Fig. 63. After diluting the H₂SO₄ with water and cooling, NaOH solution was run through the thistle funnel (a), which is connected by a rubber tube with clip and held in place by a stout copper wire (b). The bulb (d)—about 10 Cc. capacity—was intervened to prevent any NaOH solution from coming in contact with the strong H₂SO₄ in the triple bulbs (e), which, in turn, were used to prevent any NH₃ from entering the apparatus when air was drawn through—the two side bulbs having a capacity of about 6 Cc., and the middle (horizontal) one 2 to 3 Cc. The trap (e) was to prevent any solid matter being carried over during the distillation—its capacity being 15 to 20 Cc. The bulb (f), containing broken glass, is connected with the pump, while (g) is a test-tube with a small hole at the bottom. During the distillation a steady current of air was drawn through the apparatus by the suction of the pump at (f); this enabled the distillation to proceed very smoothly, with absolutely no bumping, and very little attention was required.—Chem. News, July 30, 1909, 50.

Kipp's Apparatus—New Modification.—F. A. McDermott has constructed a modified form of Kipp's apparatus which presents a number of advantages over the usual form, and in particular that it is easily charged and cleaned, and is quite substantial. As shown by Fig. 64, the upper portion of the apparatus (a) is of the usual form; the lower portion, however, consists of two parts (b and c), joined by carefully ground surfaces, the semi-globular part (b) being provided with a lateral tubulur fitted with a glass tube and cock (e) to carry off the generated gas. At a suitable height the walls of (c) are compressed so as to form an inner ledge on which a perforated circular tray (d) of porcelain or lead rests, for the reception of the material from which the gas is generated; while, near the bottom a stoppered tubular (f) is provided for withdrawing the liquid contents of (c) when the operation is ended.—Pharm. Ztg., lv (1910), No. 13, 129; from Chem. Ztg., 1910, No. 12.

Nitric Acid—Determination by Reduction with Aluminum Mercury.—Emm. Pozzi-Escot finds that aluminum mercury completely reduces nitric acid to ammonia, and thus affords a method which gives very good re-
sults in the analysis of soils and fertilizers. 4 to 5 Gm. of aluminum turnings are added to the nitrate, and enough of a saturated solution of mercuric chloride to wet it thoroughly. Then more water is added, and the mixture is left for a few minutes. When the action becomes rapid a little alkali is added and the ammonia is distilled off, some sodium hypophosphite being added at the end to decompose the mercur-ammonium compound which may have been formed.—Chem. News, Febr., 1910, 83; from Compt. rend., 149 (1909), No. 26.

Nitrohydrochloric Acid, Dilute and Strong—A Practical Suggestion.—In view of the time required in its preparation and the poor keeping qualities of "diluted nitrohydrochloric acid," A. A. Platt recommends that it be prepared as required from the strong acid, the preparation of which, in turn, can be reduced to 10 or 15 minutes instead of 24 hours, usually required to complete the reaction, by the application of heat (temperature not stated! Rep.) to the acid mixture. The acid made in this way assayed the same percentage of free Cl as that made in the usual way. The freshly made diluted acid deteriorated rapidly on standing in a warm place exposed to the light.—Amer. Journ. Pharm., May, 1910, 242.

Nitrosyl-Perchlorate—Formation and Properties.—K. A. Hofmann and Graf Arnim Zedtwitz state that when anhydrous nitric acid is added to the hydrate of perchloric acid (ClO₄H + H₂O), colorless difficulty soluble crystals are formed, which, however, are more easily prepared by conducting nitric anhydride into a solution of perchloric acid. Their formula is ClO₄NO + H₂O. They are only slightly hygroscopic, and deliquesce very gradually in moist air. An aqueous solution after warming gives both nitric acid and perchloric acid reactions. With amines nitrosyl perchlorate reacts very energetically, an explosion occurring if large quantities of substance are used. With phenols colored products are obtained; hence nitrosyl perchlorate can be used as a reagent for amines and phenols.—Chem. News, July 30, 1909, 59; from Ber. d. D. Chem. Ges. 42 (1909), No. 9.

ARGON.

Argon—Preparation from the Air.—F. Fischer and O. Ringe have worked out a method for the preparation of argon from atmospheric air. For the absorption of oxygen and nitrogen a finely powdered mixture of calcium carbide, 90, and calcium chloride, 10, is used at a temperature of about 800° C. The carbide mixture is first subjected to heat in vacuo to remove gases and tarry products. For the removal of hydrogen and hydrocarbons, the gas, after passing over the carbide mixture, is led over copper oxide at a red heat, solid caustic alkali, sulphuric acid, and phosphorus pentoxide. In this way it is possible to obtain within two days, with 7 Kgms. of calcium carbide, 11 liters of argon of a density 19.91.—
Pharm. Zentralh., 50 (1909), No. 52, 1083; from Bayr. Ind. u. Gewerbebl., 1909, 147.

PHOSPHORUS.

Phosphorus—Atomic Weight.—G. Ter Gazarian states that the determination of the atomic weight of phosphorus by chemical methods is attended by great difficulties, and that the better way is to find the density of a gas rich in phosphorus, for example, hydrogen phosphide, and from this deduce the molecular weight. A correction has to be applied for the deviation from Avogadro's law. The mean value of the atomic weight thus found is 33.930, which gives 30.906 as the atomic weight of phosphorus if \( \text{H} = 1.008 \). This value, 30.906, is the same as that obtained by Bernouilli by calculations based on the constitution of the chemical elements.—Chem. News, July 9, 1909, 24; from Compt. rend., 148 (1909), No. 21.

Phosphorus—Allotropic Modifications.—A comprehensive study and review of the literature on the allotropic modifications of phosphorus and the nomenclature pertaining to them, followed by numerous experimental examinations, lead Ernst Cohn and J. Olie to assume the existence of two allotropic modifications of phosphorus, which may be regarded as being dynamically allotropic: \( a \), the white or yellow phosphorus, and \( b \), the metallic or violet phosphorus. The so-called red phosphorus must be regarded as a solid solution of white phosphorus in the metallic. Not being a single body, the physical constants of red phosphorus are of no significance. Under the assumption advanced by the authors, numerous phenomena hitherto observed with phosphorus, are now easily and simply explained.—Pharm. Ztg., lv (1910), No. 29, 290; from Ztschr. f. physik. Chem., 71, 1–27.

Phosphorus—Allotropic States.—According to Pierre Jolibois, ordinary red phosphorus, obtained by heating yellow phosphorus, is in an unstable though definite state, and even at a temperature at which it is formed a catalytic agent is sufficient to transform it into a stable variety with a density 9 per cent. higher. This modification the author calls pyromorphic phosphorus. It may be obtained by the action of heat alone above 360° C., and in presence of a catalyzer above 250° C. Its density is 2.37. Red phosphorus can be fused by heating it to 725° C.—Chem. News, Oct. 8, 1909, 184; from Compt. rend., 149 (1909), No. 4.

Hittorf's Phosphorus—Distinctive Difference from Red Phosphorus.—Alfred Stock and Franz Gomololka state that Hittorf's red crystalline phosphorus can very readily be crystallized from a solution of phosphorus in bismuth or in lead. In order to get the crystals from a lead solution it is best to employ electrolysis, by which means about one-third of the phosphorus used is obtained in the crystalline state. It is impossible, however,
to obtain the crystals quite free from all impurities. Hittorf's phosphorus can be prepared by sublimation if the differences of temperature in the different parts of the apparatus are made as small as possible. The density of Hittorf's phosphorus is less than that of ordinary red phosphorus, and there are differences in the chemical properties; for instance, ordinary red phosphorus reacts far more readily than Hittorf's phosphorus with sulphur, and the same difference is observed when they react with sulphur and iodine dissolved in carbon disulphide. Hittorf's phosphorus slowly oxidizes in the air, while ordinary red phosphorus undergoes a fairly rapid oxidation in air, differing from white phosphorus only in the rate at which the reaction occurs.—Chem. News, Febr. 25, 1910, 96; from Ber. d. D. Chem. Ges., 42 (1909), No. 17.

*Phosphorus Hydrides—A New Solid Modification.*—Alfred Stock, Willy Böttcher, and Walter Lenger describe the method of preparation and properties of the solid phosphorus hydride, \( \text{P}_\text{H}_6 \), and of a new solid phosphorus hydride, \( \text{P}_9\text{H}_2 \). The

*Solid Phosphorus Hydride*, \( \text{P}_\text{H}_6 \), can be prepared by decomposing \( \text{P}_\text{H}_\text{a} \) by means of dry granular calcium chloride. The \( \text{P}_\text{H}_6 \) is prepared by allowing water to act upon calcium phosphide. When freshly prepared the phosphide is a canary-yellow odorless amorphous powder with no action on litmus. It acquires an acid reaction when left in air, and then smells of phosphine. It is rapidly decomposed by light, a spontaneously inflammable gas being generated. It is insoluble in all the solvents tried, except liquid phosphorus hydride and fused phosphorus. Its physiological effects are due to the gradual evolution of phosphine. The

*New Solid Phosphorus Hydride*, \( \text{P}_9\text{H}_2 \), is obtained by heating the yellow \( \text{P}_\text{H}_6 \), prepared as above, to a temperature of 200° C., when perfectly pure phosphine is evolved, which is not spontaneously inflammable. The residue left is an orange-red solid hydride of formula \( \text{P}_9\text{H}_2 \), and the simplest equation expressing its formation is \( 5\text{P}_\text{H}_6 = 6\text{P}_\text{H}_2 + 6\text{PH}_3 \). \( \text{P}_9\text{H}_2 \) is stable in dry air, but is converted into phosphine and phosphoric acid by the action of water. It is not attacked by cold water or dilute acids, but is oxidized by strong nitric acid. The same substance is obtained when liquid ammonia acts on \( \text{P}_\text{H}_6 \), \( \text{PH}_3 \) being also generated. With liquid ammonia \( \text{P}_9\text{H}_2 \) gives a red, probably colloidal, solution which on evaporation leaves a black residue consisting of a compound of \( \text{P}_9\text{H}_2 \) and ammonia, having the character of a salt. The composition of this salt varies, the values obtained on analysis lying between those given by the formulæ \( \text{P}_9\text{H}_2\cdot\text{NH}_3 \) and \( (\text{P}_9\text{H}_2)_2\cdot\text{NH}_3 \). By warming the black substance or by treating it with acids, the \( \text{P}_9\text{H}_2 \) is regenerated unchanged.—Chem. News, Oct. 22, 1909, 208; from Ber. d. D. Chem. Ges., 42 (1909), No. 12.

*Solid Yellow and Red Hydrogen Phosphide—Preparation.*—The prepa-
ration of solid yellow hydrogen phosphide, \( \text{P}_4\text{H}_6 \), is usually effected by allowing calcium phosphide and water to react upon each other and passing the gaseous product into strong hydrochloric acid, in which it is deposited as a solid. A. Stock, W. Böttcher and W. Lenger have now determined that when spontaneously inflammable hydrogen phosphide is brought in contact with calcium chloride,

**Pure Yellow Hydrogen Phosphide** (\( \text{P}_4\text{H}_6 \)) is at once separated in solid form. This, when freshly prepared, is a canary-yellow, amorphous powder, odorless and neutral, but on exposure to air acquires an acid reaction and the odor of phosphine. When heated gradually to 175° C. in a vacuum and maintained at that temperature until the evolution of gas is reduced to a minimum it is converted into

**Red Hydrogen Phosphide** (\( \text{P}_4\text{H}_2 \)) — the decomposition resulting according to the equation: 
\[
5\text{P}_4\text{H}_6 = 6\text{P}_4\text{H}_2 + 6\text{PH}_3.
\]
The new hydrogen phosphide has an intense orange-red color, and is permanent if moisture is excluded; but when exposed to the open air its weight is increased and it gradually acquires an acid reaction, being converted into phosphine and phosphoric acid.—Pharm. Ztg., l iv (1909), No. 65, 633; from Ber. d. chem. Ges.

**Phosphorus Disulphide**—**Question of Existence.**—Alfred Stock observes that if the curve of the sintering point (point at which drops of liquid appear) is plotted for mixtures of two substances, the composition of a compound can be detected far more clearly than from the melting-point curve. Moreover, the sintering point is very easy to determine and requires only a little material. The author applies this observation to the question of the existence of phosphorus disulphide (\( \text{PS}_2 \) or \( \text{P}_3\text{S}_8 \)). The determination of the sintering-point curve of mixtures of \( \text{PS}_2 \) and \( \text{P}_3\text{S}_8 \) shows that a very marked maximum occurs, corresponding to the formation of a compound of formula \( \text{P}_4\text{S}_3 \). This substance is also formed when a carbon disulphide solution of \( \text{P}_4\text{S}_3 \) and \( \text{P}_2\text{S}_5 \) is heated above 100° C. There is no indication whatever of the formation of a disulphide, and \( \text{P}_3\text{S}_8 \) is in all probability non-existent. The substances previously taken for \( \text{PS}_2(\text{P}_3\text{S}_8) \) are mixtures of \( \text{P}_3\text{S}_7 \) and \( \text{P}_2\text{S}_6 \)—Chem. News, July 30, 1909, 60; from Ber. d. D. Chem. Ges., 42 (1909), No. 9.

**Tetraphosphorus Trisulphide**, \( \text{P}_4\text{S}_3 \)—**Preparation and Properties.**—According to Alfred Stock, to prepare pure tetraphosphorus trisulphide 4 atomic weights of red phosphorus are carefully heated with 3 atomic weights of sulphur in an atmosphere of dry carbon dioxide. Thus a mixture of red phosphorus and \( \text{PS}_3 \) is obtained. The latter may be separated off by extraction with carbon disulphide, and the raw product purified by treatment with hot water. The purified sulphide can then be removed by filtration or by treatment with carbon disulphide. Its melting point is 171–172.5° C. It is very soluble in carbon disulphide, forming a yellow solution. When finely divided it reacts energetically with caustic potash,

Tetraphosphorus Heptasulphide, \( \text{P}_4\text{S}_7 \)—Preparation and Properties.—To prepare tetraphosphorus heptasulphide (\( \text{P}_4\text{S}_7 \)), Alfred Stock mixes 100 parts of red phosphorus with 173 parts of sulphur, and treats the mixture as in the preparation of \( \text{P}_2\text{S}_4 \) (which see). It is strongly heated for some time, and the cooled product is powdered and recrystallized from carbon disulphide. The low solubility of \( \text{P}_2\text{S}_4 \) in carbon disulphide is a property which distinguishes it from the other sulphides of phosphorus. The vapor density of the heptasulphide corresponds to the formula \( \text{P}_2\text{S}_7 \) up to about 700° C., and above 750° C., rapidly falls to the half value. The crystals of \( \text{P}_2\text{S}_7 \) are almost colorless with a faint tinge of yellow. They have no sharp melting-point, but fuse to a pale yellow liquid at 305°–308°–310° C. The boiling-point at 760 Mm. pressure is 523° C., and the density at 17° C. is 2.19. \( \text{P}_2\text{S}_7 \) is much more sensitive to water than \( \text{P}_2\text{S}_4 \), and smells strongly of sulphuretted hydrogen after standing in air for some time. It is slowly decomposed by cold water, and rapidly on warming. Alkaline liquids readily dissolve it in the cold.—Chem. News, April 8, 1910, 167; from Ber. d. D. Chem. Ges., 43 (1910), No. 2.

Phosphorus Dichloride—A New Compound.—By the action of electricity on mixtures of phosphorus trichloride and hydrogen, A. Besson and L. Fournier have obtained phosphorus dichloride, \( \text{P}_2\text{Cl}_4 \). It is a colorless oily liquid having a smell of phosphorus. It forms a white solid at—28° C. It fumes in air, partly because it is decomposed by moisture, and also because it is readily oxidized, and often ignites spontaneously. It is unstable, but may be distilled in an inert gas at atmospheric pressure without undergoing much decomposition. It decomposes slowly at the ordinary temperature, giving a light yellow solid of composition \( \text{P}_2\text{Cl}_4 \). Attempts to obtain the dibromide similarly have led to the formation of a yellow solid, which may be a decomposition product of the dibromide.—Chem. News, Mar. 4, 1910, 107; from Compt. rend., 150 (1910), No. 2.

Hypophosphorous and Phosphorous Acids—Reducing Action on Certain Metallic Salts.—A. Sievertz finds that aqueous solutions of hypophosphorous acid and hypophosphites are decomposed at ordinary temperatures by palladium; then reduced cobalt and nickel react, but gold, silver and copper require prolonged exposure at 100° C. to effect decomposition. Platinum black does not act as a catalyzer. Gold chloride reacts with both phosphorous and hypophosphorous acids, with separation of metallic gold. Cupric chloride is reduced to cuprous chloride by phosphorous acid. Phosphorous acid reduces cupric sulphate, with precipitation of metallic copper. Cupric sulphate and hypophosphorous acid react differently in varying proportions. If the copper salt be in excess metallic
copper is precipitated without any liberation of hydrogen; but if hypophosphorous acid is in excess copper hydride is precipitated. Platinum chloride is not reduced to the metallic state by hypophosphorous acid, but palladium chloride is quickly reduced in the cold. Nickel and cobalt salts are not reduced by either acid.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 671; from Ztschr. Anorgan. Chem., 64 (1909), 29.

**Hypophosphoric Acid—Confirmation of Double Formula.**—Results obtained by E. Cornec when the lowering of the freezing-point of hypophosphoric acid in aqueous solution is determined point very decisively to the double formula \( \text{H}_3\text{P}_2\text{O}_6 \), and this is confirmed by similar experiments with the potassium salt, as well as by a comparison of the conductivity of the neutral sodium salt with that of sodium pyrophosphate.—Chem. News, Mar. 4, 1910, 107; from Compt. rend., 150 (1910), No. 2.

**Phosphoric Acid—Determination in Acid Solution with Alkaline Molybdate Solution and Glue.**—According to A. Grete, phosphoric acid can be determined in acid solution by mixing with a solution of glue, adding ammonium nitrate and nitric acid, boiling, and allowing molybdic acid solution to drop into the mixture from a burette until a distinct precipitate remains. The solution is again boiled and well shaken, when a compact yellow precipitate settles. More molybdate is added, and the mixture is again boiled until the addition of molybdate no longer produces a precipitate. From the volume of molybdic solution thus used the percentage of phosphoric acid in the original solution can be calculated. The molybdic acid solution is prepared by adding a concentrated solution of molybdic acid in ammonia to nitric acid till the precipitate obtained does not dissolve, and adding ammonia. It is then titrated with a \( \text{KH}_2\text{PO}_4 \) solution; 1 Cc. of solution should equal 0.0025 Grm. \( \text{P}_2\text{O}_5 \). The ammonium nitrate-nitric acid solution contains 200 Grms. of ammonium nitrate and 26.5 Cc. of nitric acid (sp. gr. 1.197) in 1 liter. The solution of glue has to be carefully made by allowing glue to stand in cold water, then pouring off the water and boiling with water and nitric acid; after cooling, the solution is made ammoniacal and any phosphoric acid present is precipitated with magnesia mixture. Then ammonium carbonate is added, and portions of the solution are filtered off as required.—Chem. News, Oct. 29, 1909, 220; from Ber. d. D. Chem. Ges. 42 (1909), No. 13.

**Boron.**

**Borax—Proposed Elimination from Tinctura Rhei Aquosa and Sirup. Rhei, G. P.**—Dr. O. Langkopf calls attention to the anomaly that, while the Imperial Health Office has pronounced borax as injurious to health and its use as a preservative for foods has therefore been forbidden, it is retained as a component of two preparations of the G. P., namely tinctura rhei aquosa and siripus rhei. An experimental inquiry into the probable necessity or utility of borax in these preparations (about 0.9 per cent. in
the tincture and 0.5 per cent. in the syrup) lead him to the conclusion that there is no necessity for its presence nor any advantage to be gained thereby, and he emphatically recommends its elimination from these preparations, if for no other reason, for its presence in them is in direct conflict with its own verdict by the health office.—Pharm. Ztg., lv (1910), No. 23, 231.

SILICON.

Glass—Penetration by Gases.—In order to investigate the correctness of the statement of Zengheli that many gases or vapors of solid substances can pass through glass at the ordinary temperature, Alfred Stock and Hans Heyneman made the following experiment: A piece of silver foil was placed in a flask of ordinary glass, which was then exhausted. It was then left in a closed vessel in which iodine crystals were present. After three months nitric acid was added in order to see whether the silver dissolved completely, or whether any silver iodide had been formed owing to the penetration of the iodine vapor through the glass. It was found that there was no trace of iodide formed, and thus the statement of Zengheli appears to be incorrect.—Chem. News. July 9, 1909, 24; from Ber. d. D. Chem. Ges., 42 (1909), No. 8.

Ferro-Silicon—Evolution of Poisonous Gases.—The “British Medical Journal” mentions that certain cases of poisoning from exposure on shipboard to the fumes of ferro-silicon, which were at one time obscure, have now been thoroughly elucidated. In December last five such deaths occurred among Russian immigrants between Antwerp and Grimsby. Previously, in 1905, two children were fatally poisoned on a canal boat which had a cargo of ferro-silicon. It is now found that a ton of the material gave off 161 liters of phosphoretted hydrogen and 7 liters of arsenuretted hydrogen, so that the dangerous nature of such material as cargo is established. It should be shipped only in soldered, metal, gas-proof cases.—Pharm. Journ. and Pharmacist, July 17, 1909, 73; from B. M. J., 1909, 2, 42.

CARBON.

Carbon—Composition of the Ordinary Forms.—H. Le Chatelier and M. Wologdine have performed many experiments in order to ascertain whether there are several varieties of ordinary carbon, which are the products of progressive polymerizations, and which have different densities and heats of combustion. They have found that in all varieties of ordinary carbon there is a considerable proportion of graphite, and they believe that there is only one variety of ordinary carbon of density about 1.8, the lower densities being due to the presence of included gases. It is not, however, possible to affirm with certainty the non-existence of several varieties of ordinary amorphous carbon.—Chem. News, Sept. 24, 1909, 160; from Compt. rend., 148 (1909), No. 26.
Amorphous Carbon—Decolorizing Properties of Various Kinds.—In consequence of conflicting statements with regard to the decolorizing property of charcoal, some authors insisting upon a relationship existing between the chemical constitution of the carbon and its absorbent power, and others that the absorption power for "Crystal Ponceau" varies according to the proportion of nitrogen content, L. Pelet and C. Mazzoli have made a series of experiments, with a large number of decolorizing charcoals to elucidate the question. After determining the water and ash, the absorption results were taken as relating to 100 Gm. of the organic matter, first having shown that calcium carbonate, calcium phosphate, ferric oxide, etc., have no absorptive power towards the coloring matters. Sixteen samples were examined, comprising blood charcoal, bone charcoal, animal charcoal, wood charcoal, lamp-black, and decolorizing charcoal of Stassfurt, known as RT, ETB, and ET, these three last being manufactured by a secret process. The results of experiments made to determine any relationship between the nitrogen content and absorptive power show that no such relationship exists. The various samples were treated as follows: (1) Washed for a long time with hot distilled water; (2) heated repeatedly with concentrated hydrochloric acid to eliminate soluble mineral matter; (3) treated for three hours with hot concentrated sulphuric acid to destroy supposed cyanogen groups; (4) heated for three hours with concentrated solution of sodium hydroxide to eliminate NH₂ groups; (5) treated with sodium nitrite and hydrochloric acid to destroy NH₂ groups, then heated to boiling. After such treatment the samples were washed with water until the conductivity of the wash-water remained constant, this being necessary on account of the influence of electrolytes on the absorption of coloring matters. Examination of the samples thus purified showed that the decolorizing power had not sensibly been modified. The authors conclude that the absorbent power of decolorizing charcoal cannot be explained by the presence in it of nitrogen or of chemically active azotized groups.—Pharm. Journ. and Pharmacist, Dec. 11, 1909, 731; from Bull. Soc. Chim., Nov., 1909, 1011.

Animal Charcoal—Arsenic a Contaminant.—Bruno and Turquand d'Auzay, interested in the question whether the use of animal charcoal contaminated with arsenic might not impart a trace of this contaminant to wines when used as a decolorizing agent, have examined nine samples of animal charcoal. Three of these were perfectly free from arsenic; three contained only minute traces; the remaining three contained from 8 to 22 Mgm. of arsenic in 100 Gm. It was found, however, that when the animal charcoal containing the highest arsenical contamination was added to wine, in the proportion of 10 Gm. per liter, and allowed to macerate two weeks, the decolorized wine did not contain a trace of arsenic. It is therefore concluded that ordinary commercial animal charcoal, even when contaminated with arsenic, may safely be used as a decolorizing agent for
Graphite—Estimation.—In a previous paper F. Browne has shown that the amount of carbon in graphite could easily be ascertained by means of a specially prepared iron oxide. The examination of a sample of “Acheson” graphite has confirmed the previous statement that the oxide of iron remains at the end of the estimation in the same condition as at the commencement. It was found that the prepared iron oxide after having been kept a year was still serviceable. Five Gm. of such heated in an open crucible to a pale red for an hour did not thereafter alter in weight, and was quite ready for an estimation. The “Acheson” graphite—grade No. 1,340, as made in the electric furnace—contained 0.158 of mineral matter and 0.170 of water, and its purity was 99.672 per cent.—Chem. News, Oct. 1, 1909, 162.

Lampblack—Inferior Commercial Quality.—F. H. Alcock directs attention to the inferior quality of the “lampblack” supplied on the market. According to good authority lampblack is “a deposited soot from the incomplete combustion of resin and tar.” Neither of these contain much, if any, ash, and certainly less than 1 per cent. Yet the samples of lampblack, so labelled and wrapped in the familiar way, yielded from 8.6 to as much as 36 per cent. of ash, whilst other commercial blacks (mineral-black and ivory-black) yielded about 62 per cent. of ash.—Chem. and Drugg., Sept. 11, 1909, 443.

Solid Carbonic Acid—Formation of Pencils with Blotting-Paper Moulds.—Sinclair Tousey describes the following method for preparing pencils or crayons of solidified carbonic acid, which has lately attracted attention on account of its dermatological value in the treatment of naevus, lupus, warts, condylomata, moles and epitheliomata. He has devised for this purpose blotting-paper moulds, consisting of a hollow cylinder made by rolling several layers of blotting paper around a lead pencil or a glass vial, which is then removed. The blotting paper must be absorbent all the way through, not sized on one side, like so many advertising blotters. One end of the tube thus formed is tightly stoppered. The other end is placed tightly against the nozzle of the liquid carbonic-acid tank and wrapped around with adhesive plaster to make an air-tight joint. The carbonic acid cylinder employed is a small one, 18 inches long and 4 inches in diameter, and containing 5 pounds of the liquefied gas. It is laid on its side with the lateral nozzle turned downward. The liquid should be allowed to flow out into the porous paper tube. A portion immediately vaporizes and escapes through the meshes of the paper, producing cold enough to freeze the remainder. The liquid is allowed to flow very slowly, taking perhaps a minute to fill the tube. Turning it on full force would blow the tube off, and waste a great deal of the liquid. When
the mould is full of ice the liquid will begin to spurt out around the adhesive plaster, and the flow should then be turned off. The adhesive plaster being unwrapped, the porous paper cylinder will be found to contain a crayon of carbonic acid resembling very much the crayons used for writing on a blackboard. The blotting paper may be unwrapped from one end of the crayon so as to expose the latter. Or after waiting a short time the crayon will be found to have lost some of its substance by direct evaporation and to lie loose in the blotting-paper tube. The crayon may be made to protrude as much as desired by holding the tube upside down with something underneath to prevent the crayon falling out altogether. The blotting paper is flexible enough and a sufficient non-conductor of heat to serve as a handle for the crayon, which must not be touched by the naked hand.

It is not practicable to secure ice crayons with the carbonic-acid cylinder in an upright position, because then only the gas above the surface of the liquid could reach the nozzle and escape. None of the actual liquid would be let out of the tank in this way.—Pharm. Journ. and Pharmacist, May 28, 1910, 675.

True Percarbonates—Question of Existence.—Riesenfeld and Reinhold have observed that potassium percarbonate separates iodine from potassium iodide, while carbonates with hydrogen peroxide of crystallization do not. This, however, according to S. Tanator was to be expected, for the solution of potassium percarbonate contains potassium bicarbonate, while no bicarbonate is present in his sodium percarbonate. Hydrogen peroxide separates iodine from potassium iodide in presence of bicarbonates, while in presence of carbonates the iodine immediately yields salts of hypoiodous acid. These then decompose with evolution of oxygen. Since Riesenfeld and Reinhold added sulphuric acid to the solution, what they have determined is not the amount of iodine which results from the action of percarbonate on neutral potassium iodide, but the amount of iodine which is set free when percarbonate or hydrogen peroxide acts on hydriodic acid.—Chem. News., Mar. 18, 1910, 132; from Ber. d. D. Chem. Ges., 43 (1910), No. 1.

Monochlor- and Monobrom-Acetylene—Formation of Metallic Salts.—K. A. Hoffmann and H. Kirmreuther have prepared and describe several metallic salts of monochlor- and monobrom-acetylene. They find that mercuric tribromethylidenel, Hg(CBr\( \cdot \)CBr\( \cdot \))\( 2 \), prepared from acetylene tribromide, is very stable and forms characteristic crystals. Alkaline mercury cyanide solution gives with dichlorehylene a good yield of mercuric chloracetylide, Hg(C:CCl)\( 2 \), which, when warmed with potassium cyanide and caustic potash, liberates perfectly pure chloracetylene. Bromacetylene can be prepared similarly. Both substances yield metallic compounds similar to those obtained with acetylene, and there seems to
be no reason for rejecting the usual formulæ \( CH : CCl \) and \( CH : CBr \). Besides the normal silver, copper, and mercuric salts, monochloracetylene yields trichlormercury-acetic acid, \((\text{ClHg})_3\text{C.CO}_2\text{H}\), with mercury chloride. When chloracetylene is led into ammoniacal silver nitrate solution, the white precipitate obtained very readily turns brown in air, and after being dried explodes. With cold saturated mercury chloride solution chloracetylene gives \( \text{tris}-\text{chlormercury-acetic acid, (ClHg)}_3\text{C.CO}_2\text{H} \).—Chem. News., Jan. 21, 1910, 35; from Ber. d. D. Chem. Ges., 42 (1909), No. 16.

**Cyanogen.**

*Hydrocyanic Acid—A New Sensitive Test.*—J. Moir having found the guaiacum test unsatisfactory and the phenolphthalin-copper test sometimes inapplicable, has succeeded in finding a reagent which will detect hydrocyanic acid in a dilution approaching one part in five millions of water. The test depends on the oxidation of a leuco-compound by nascent cyanogen resulting from the action of cupric copper on cyanides, but the author finds that none of the common leuco-compounds can be used. The reagent is made by adding small quantities of copper acetate and acetic acid to a warm solution of hydrocœrulignone (tetramethoxydiphenol) in a large quantity of water, digesting the mixture at 50° for a few hours, and filtering. The solution to be tested is rendered faintly acid with acetic acid (using sodium acetate also if a "strong" acid is present), and then treated with about one-quarter of its volume of the reagent. In solutions stronger than 1 in 100,000 an immediate crystalline precipitate of cœrulignone (red with purple luster) is obtained; with weaker solutions, a brick-red coloration. Oxidizing substances must, of course, be absent, but most of them can be avoided by applying the test on paper exposed to the vapor evolved by the liquid to be tested, as in the guaiacum test. A similar reaction is given by other tetra-substituted diphenols and by benzidine and its derivatives. Benzidine gives an indigo shade; dianisidine, bluish-green; and tolidine, a green shade. Although not so sensitive as hydrocœrulignone these reagents are more trustworthy and keep much better. The colors produced are all derivatives of so-called diphenoquinhydride.—Pharm. Journ. and Pharmacist, June 18, 1910, 760; from Proc. Chem. Soc., May 14, 1910, 115.

*Hydrocyanic Acid—Detection by means of Test Papers.*—H. Barthe says that two kinds of test paper have been recommended for the detection of the vapor of hydrogen cyanide:—Guignard's picro-soda paper, prepared by dipping filter paper in a solution of 1 of picric acid in 100 of hot water, after adding to the solution 10 of sodium carbonate; this paper is colored red by hydrocyanic acid vapor; and Thiéry's phthalophenone paper, prepared by dipping filter paper in a solution of copper sulphate and then in an alcoholic solution of phthalophenone. This paper gives a rose color
with hydrocyanic acid vapor; but it has been asserted by Volcy-Boucher that this color is developed spontaneously on simply exposing the paper to the air at ordinary temperature, and recent experiments confirm this statement. It is, therefore, recommended that only the micro-soda paper should be employed for this test.—Pharm. Journ. and Pharmacist, Jan. 1, 1910, 7; from Bull. Soc. de Pharm. de Bordeaux, through Rép. de Pharm., Oct. 10, 1909, 440.

ALKALIES.

_Potassium Hydroxide—Precaution in Purification by Alcohol._—A deficiency of KOH in a sample of potassium hydroxide purified by alcohol induced H. J. Henderson to ask the manufacturer for an explanation, who replied that it is impracticable to make a pure potassium hydroxide stronger than 85 per cent, KOH, because on the concentration of the solution in silver vessels, to cast the compound into sticks, this has to be done when about 85 per cent. strength is reached. If this precaution is not taken, the silver is attacked and contaminates the product. The exact point is, however, difficult to determine; hence a variation of 2–3 per cent. from this standard is unavoidable. Potassium hydroxide of technical quality, for which such metals as iron do not matter, can be made of about 100 per cent. standard of KOH.—Pharm. Journ., Nov. 6, 1909, 564.

_Caustic Potash—Paraffin in Commercial Sticks._—F. Benger calls attention to commercial stick caustic potash which had evidently been coated with a thin layer of paraffin, either used to prevent deliquescence, or possibly employed as a lubricant of the moulds. He has isolated 0.544 Gm. of viscous fluid paraffin from a kilo of the sticks. Attention is directed to the fact that the presence of this impurity might lead to error if such potash were used for the determination of unsaponifiable constituents in fats, and for similar tests.—Apoth. Ztg., xxv (1910) No. 24, 201.

_Potassium Salts—Radio-Activity._—The examination by Emile Henriot and G. Vavon of the chloride and sulphate of potassium by the electrical methods confirms the hypothesis that the radio-activity of potassium is due to the element itself and not to an unknown impurity. The rays possess the penetration of β-rays, and, moreover, in a magnetic field they behave like a flow of negative electricity, and hence there is no doubt that they are β-rays.—Chem. News, Oct. 1, 1909, 172; from Compt. rend., 149 (1909), No. 1.

_Potassium Carbonate—Degrees of Hydration._—M. de Forcrand, mentions that six hydrates of potassium carbonate have been described, viz., those with 4, 3, 2, 1½, 1, and 0.5 H₂O, but that the only one which undoubtedly exists, or rather the only one which can always be prepared in ordinary conditions, is K₂CO₃·1.5H₂O. From experiments in which the heats of solution of K₂CO₃ and K₂CO₃·1.5H₂O were determined, it appears that the hydrate with 1.5H₂O is not a dehydrating agent, and for
dehydrating purposes the anhydrous salt should be used. The use of
K$_2$CO$_3$ for dehydration demands certain precautions. It is possible that
hydrates with 3 or 4 H$_2$O exist at low temperatures.—Chem. News., Sept.

*Potassium Chlorate.*—A. R. L. Dohme and H. Engelhardt discuss the
subject of dangerous impurities in potassium chlorate which are liable to
induce spontaneous explosion, in a paper which appears in the "Proceed-

*Fused Caustic Soda—Action of Metals.*—M. LeBlanc and L. Bergmann
have studied the effect of metals on fused caustic soda. When this is
heated in a gold vessel to 400° C. in an atmosphere of dry nitrogen it is
readily dehydrated, and gives up no more water when the temperature is
raised to 720° C. The average amount of water given up at 400° C. is
2.44 per cent. Evidently caustic soda does not dissociate at these tem-
peratures according to the equation 2NaOH = Na$_2$O + H$_2$O. Gold has
no action on dry fused caustic soda in absence of air between the above
temperatures. Silver and sodium liberate hydrogen, while platinum,
copper, iron, nickel, aluminum, zinc, and magnesium generate hydrogen,
and water is simultaneously formed. This double reaction may be ex-
plained on the assumption that the metal-sodium oxide compound result-
ing from the reaction, Me + $x$NaOH = Me (ONa)$_x$, forms a complex
compound with sodium oxide, and that then the reaction 2NaOH =
Na$_2$O + H$_2$O can occur. The gold vessel, when heated with copper and
c austic soda to 700° C., yields an alloy which is not formed in absence of
the alkali, and a gold-magnesium alloy has also been obtained similarly.—
No. 18.

*Sodium Carbonate—Rapid Determination of Bicarbonate Present.*—
B. Loüinger observed that in the production of sodium carbonate by elec-
trolysis of sodium chloride, caustic soda sometimes occurred in the mother
liquor, and was found later to have disappeared, showing that in the mean-
time some bicarbonate must have been produced. The best way of de-
termining the latter was found to be to add to some of the liquor a known
quantity of caustic soda, whereby any bicarbonate is converted to carbo-
nate, then excess of barium chloride, which precipitates all the carbonate;
then without filtering off the precipitate, the excess of caustic soda re-
main in solution is titrated with standard acid, using phenolphthalein
as indicator. The amount of caustic soda which has disappeared is
equivalent to the bicarbonate that was present; if, on the other hand, the
liquor contained some caustic and no bicarbonate the same titration will
show the amount of caustic present. Any error due to carbonate in the
custic soda added is eliminated by a blank control test.—Pharm. Journ.
and Pharmacist, Febr. 12, 1910, 173; from Chem. Ztg., Nov. 6, 1909,
1174.
Sea Salt—Source of Principal Supply.—Felix J. Koch says that much of the sea salt sold in the United States comes from Austria, where the government derives no little increment from the sale, for the taxes of certain localities are founded on this salt—plain, every-day sea salt. The seat of the Austrian salt industry on the Adriatic is at Capo d' Istria, but salt works are also operated at Pirano, Istria, Arbe, Pago, and Stogno, and with the exception of the Pirano plant, where a new method is being attempted, the systems are conducted at a tremendous profit. In the salt marshes of Capo d' Istria the process is rather simple, consisting of the old method of out-door evaporation. The sea water at this place contains about 3.75 per cent. of solid matter, about \( \frac{3}{5} \) of which consists of common salt, which however is not deposited until the volume of the water is reduced \( \frac{2}{5} \) of its original solution. Other salts besides the derived sodium chloride being likewise deposited, the concentrated brine is now drawn into a level field in the marsh which has been coated with clay to prevent the water seeping away from this into a second similarly prepared field, and so on through a series, until the liquor becomes so concentrated as to flow only sluggishly, until finally the separated salt may be gathered in little heaps and carted, when dry, into the bins. This interesting paper will well repay consultation in the original.—Merck's Rép., Nov. 1909, 286.

"Bush-Salt"—An African Condiment.—Lenz calls attention to "bush-salt" used by the natives in the regions of Africa where salt is scarce as a substitute for common salt and also as a medicine. It consists simply of the ash of several plants, prepared according to Tessmann from the leaves of Halopegia azurea, Cystosperma senegalense, and, rarely, of the Raphia palm. The sample examined by Regenstein contained 43.3 per cent. KCl, 27.5 per cent. K₂SO₄, 16.26 per cent. K₂CO₃, 0.85 per cent. NaCl, 8.25 per cent. H₂O and 3.34 per cent. insoluble substance containing Ca, Mg, Fe, Al, Phosphates, Silicates, Carbonates, and free (0.7 per cent.) Silica. The salt is brownish, hygroscopic and granular.—Pharm. Ztg., lv (1910), No, 46, 471; from Ber. d. Pharm. Ges., 1910, No. 5.

Ammonium Nitrate—Utility in the Analysis of Metals.—Ammonium nitrate melts easily at about 150° C. and begins to decompose at 210° C. L. Loviton finds that if, into the melted salt, in a test-tube or porcelain capsule, certain metals are introduced, particularly copper, zinc, or nickel, they are vigorously attacked and dissolved, whereas the other common metals such as iron, tin, and antimony remain unaffected, or only very slowly and slightly so. This fact may be made use of in certain cases, such for example where iron or steel is coated with copper, brass, or nickel, and a separation and estimation may be made in a few minutes. For this purpose, a weighed quantity of the sample to be tested (2 to 4 Gm.) is introduced into the fused ammonium nitrate and heated for a few moments until the reaction has terminated. On treating the "melt"
with water, the unaffected iron is separated, dried, and weighed, and the coating of copper, brass, or nickel determined by difference.—Pharm. Journ. and Pharmacist, Oct. 9, 1909, 451; from Ann. de Chim. Analyt., Sep. 15, 1909, 328.

**Ammonium Phosphate—Volumetric Determination.**—Finding the quantitative requirements of the B. P. for the estimation of ammonium phosphate faulty, John M. Wilkie has worked out a volumetric method, which consists in a simple modification of his method for the determination of phosphoric acid in which the acetic acid, liberated on adding silver nitrate in the presence of sodium acetate, is titrated with standard alkali in the presence of phenolphthalein. In the experiments the ammonium phosphate employed was of a high degree of purity, though somewhat deficient in ammonia. Chlorides and sulphates were entirely absent—in fact the only impurity detected was a trace of sodium. For all the quantitative determinations a solution was prepared containing 13.209 Gm. per liter, this solution being \( \frac{2}{10} \) for the ammonia and \( \frac{3}{10} \) for the phosphoric acid (\( \frac{1}{10} \) PO₄).

After various trials the following procedure was adopted:

Ten Cc. of the above solution was transferred to a round-bottom Jena flask (such as is used in Kjeldahl determinations), 30 Cc. \( \frac{5}{10} \) NaOH was added, the flask clamped in an inclined position and boiled until the volume was reduced to about 5 Cc.; 30 Cc. \( \frac{5}{10} \) H₂SO₄ was next added, and the contents again boiled for a few minutes to expel carbon dioxide. The flask was then cooled in running water, 3 to 5 Cc. 20-per cent. sodium acetate, and then 33 Cc. \( \frac{5}{10} \) AgNO₃ added. The flask was corked and the contents well shaken, a few drops of phenolphthalein solution added, and then \( \frac{5}{10} \) baryta was run in until a permanent pink tint was produced, most clearly seen when the precipitate is given a moment to settle.

The end point is sharp and permanent, and easy of recognition. If the salt is exactly 100 per cent., 30 Cc. \( \frac{5}{10} \) Ba(OH)₂ will be required, and so the percentage is obtained by multiplying the number of Cc. consumed by \( \frac{1}{3} \).—Chem & Drugg., August 28, 1909, 379.

**Nessler’s Reagent—Preparation.**—Dr. Friedrich Tretzel breaks a lance for the well-known Nessler’s reagent as a test for ammonia, finding it extremely delicate for this purpose and perfectly replacing the more or less complicated methods that have been proposed. The preparation of the reagent is quite simple, and its efficiency is assured if the following directions are strictly followed: 5 Gm. mercuric chloride are dissolved by the aid of heat in 80 Cc. of distilled water and 30 Gm. potassium hydroxide are dissolved in 60 Cc. of cold water. Then 10 Gm. potassium iodide are dissolved with heat in 10 Cc. of distilled water contained in a 300 Cc. Erlenmeyer flask, and sufficient of the hot solution of mercuric chloride is added gradually, rotating the flask, until a faint turbidity sets in and dis-
appears slowly on further rotation. Now, a further addition of mercuric chloride is made very carefully by dipping a glass rod into the mercuric chloride solution and stirring the contents of the flask with it until a very faint permanent turbidity is produced—for, if a decided permanent precipitate is produced, the mixture is worthless. The liquid is now filtered, the solution of potassium hydroxide is added, followed by sufficient distilled water to make 200 Cc. Finally, 1 Cc. of the original mercuric chloride solution is added, the mixture is well shaken and, after subsidence, decanted clear into the reagent bottle. The reagent produces a distinct yellow color in water containing as little as 0.0125 Gm. ammonia in 100 liters.—Pharm. Ztg., liv (1909), No. 58, 568.

Thioformamide—Preparation and Properties.—Richard Willstätter and Theodore Wirth state that thioformamide (H.CS.NH₂) may be prepared by the action of phosphorus pentasulphide on formamide. An oily product is thus obtained, which exhibits the reactions of a thioamide. The isolation of pure thioformamide depends upon the fact that it yields a hydrate which is soluble in water, but unlike the oxygen compound, is extracted from an aqueous solution by means of ether. Thioformamide crystallizes in colorless prisms, which melt to a yellow oil at 28°–29° C. It decomposes readily. With one mol. of hydrochloric acid it forms a salt which is also very easily decomposed. With chloracetaldehyde it yields thiazol, and with bromethylamine the previously unknown “thiazolin.” When heated it decomposes chiefly into sulphuretted hydrogen and hydrocyanic acid (H.CS.NH₂ = CNH + H₂S).—Chem. News, July 30, 1909, 59; from Ber. d. D. Chem. Ges., 42 (1909), No. 9.

Sulphamide—Conditions of Formation.—Fritz Ephraim and Mr. Gur-ewitsch observe that sulphamide belongs to the class of substances which are difficult to prepare, though their composition is simple. The authors have obtained a good yield of it as follows: They allowed sulphuryl chloride to drop into liquid ammonia surrounded by a freezing mixture. The reaction 2SO₂Cl₂ + 7NH₃ = NH(SO₂.NH₂)₂ + 4NH₄Cl then occurs rapidly, i.e., the ammonium salt of imidosulphamide is formed. The mixture obtained is dissolved, acidulated, and gently warmed, and thus a mixture of ammonium chloride, amido-sulphuric acid, and sulphamide is obtained. The sulphamide is removed by adding dry acetic ether, in which it alone is soluble.—Chem. News, Mar. 18, 1910, 132; from Ber. d. D. Chem. Ges., 43 (1910), No. 1.

Rubidium and Caesium Carbonates—Degrees of Hydration of the Neutral Salts.—M. de Forcrand has determined the heats of solution of the neutral carbonates of rubidium and caesium, from which it appears that rubidium carbonate resembles potassium carbonate as far as the degree of hydration is concerned (1.5H₂O), while caesium carbonate differs from them (3.5H₂O). Thus the formulæ are 2M₂CO₃ + 3H₂O for K₂ and Rb₂ and
2Cs₂CO₃ + 7H₂O. The results obtained when the hydrates of Rb₂CO₃ and Cs₂CO₃ are subjected to the action of heat seem to show that there are several hydrates between the monohydrate and the anhydrous salt, corresponding to different degrees of condensation of the molecule, but the author has not isolated these compounds. The anhydrous carbonates are powerful dehydrating agents, being even more active than anhydrous K₂CO₃.—Chem. News, Oct. 1, 1909, 172; from Compt. rend., 149 (1909), No. 1.

Rubidia and Cæsia—Formation of Hydrates.—M. de Forcrand finds that when a concentrated solution of rubidia is allowed to evaporate in the cold crystals of formula RbOH + 2½H₂O separate. These are probably the hydrate with two molecules of water, still retaining some traces of mother-liquor. There is a complete analogy between potash and rubidia, except that the latter has a higher affinity for water, and is therefore a more effective dehydrating agent than potash. All attempts to isolate a dihydrate of cæsium have failed.—Chem. News, Febr. 18, 1910, 83; from Compt. rend., 149 (1909), No. 26.

Alkaline Earths—Micro-Chemical Detection.—N. Schoorl describes micro-chemical tests for the detection of barium, strontium and calcium. The most characteristic micro-chemical reaction for barium is the formation of the fluoro-silicate. This salt is precipitated in a distinctive crystalline form from acetic acid solutions by means of ammonium fluoro-silicate. For strontium, the chromate is the most suitable salt for microscopic recognition; for calcium, the precipitation of calcium sulphate in typical crystals from acetic acid solution. The different solubility of the anhydrous chlorides in absolute alcohol may be employed for the separation of the salts, and these may be identified as anhydrous nitrates. Calcium may be detected in presence of strontium and barium by evaporating a few drops of the acetic acid solution to dryness with excess of sulphuric acid, incinerating the residue, and gently warming it with a little water. A few drops of the clear liquid are removed by means of a capillary tube, transferred to a micro-slide, treated with a trace of acetic acid, and allowed to crystallize.—Pharm. Journ. and Pharmacist, Sept. 11, 1909, 342; from Ztschr. Analyt. Chem., 48 (1909), 401.

Pure Calcium Carbonate—Preparation.—Dr. M. Kleinstück points out the difficulty of obtaining perfectly pure calcium carbonate on the market, the product supplied invariably containing traces of ammonium or sodium salts, depending on the precipitant used, while the temperature at which the precipitation is effected affects the amount of contaminant. He therefore describes and recommends the following method and process which secures a perfectly pure calcium carbonate: The hot calcium chloride solution is precipitated with ammonium carbonate and ammonia water,
the precipitate allowed to settle, and washed with hot distilled water, by
decantation, until the washings no longer give a reaction with Nessler's
reagent. Then, to remove the last traces of ammonium salts, the precipi-
tate is heated repeatedly with perfectly neutral solution of calcium chloride
and washed with distilled water until the washings no longer give a reac-
tion for chlorine.—Pharm. Zentralh., 51 (1910), No. 4, 63–64.

Precipitated Calcium Carbonate—Copper Introduced by the Distilled Wash
Water.—Having prepared some precipitated calcium carbonate according
to the directions of the G. P., M. Lefeld found on subjecting the product to
examination appreciable traces of copper, which, on further investigation,
was evidently introduced by the distilled water employed for washing the
precipitate. The distilled water was an industrial condensation product
containing carbonic acid, which in contact with the copper condensing
tubes had evidently acted upon the copper with formation of copper car-
bonate in solution. This, reacting with the calcium carbonate, is con-
verted into insoluble basic copper carbonate, and to the extent of its
presence contaminates the officially prepared product. Further experi-
ments actually demonstrated that when water containing CO₂ is in contact
with metallic copper, appreciable quantities of copper are dissolved,
whereas distilled water, free from CO₂, is without effect upon it.—Pharm.

Magnesia Usta, G. P.—Modification of Official Test.—H. Frerichs and
W. Kroseberg record the results of an examination of ten specimens of
calcined magnesia—seven obtained from pharmacists, two from manufac-
turers, and one designated as "chemically pure." Only one of the sam-

les responded completely to the demands of the G. P., which consist
simply of the absence of impurities in excessive quantities, while two others
very nearly responded to the official requirement. But in all cases there
was a considerable variation in the alkalinity, which ranged from 86.30
per cent. to 94.80 per cent. MgO. The higher figure was attained with
the so-called "chemically pure" sample, which however cannot be
accepted as C. P. since it contains both iron and other heavy metals as
impurities. The variation observed in the MgO content of the different
samples, while partly due to the presence of magnesium as carbonate, is
mainly due to moisture which is not taken into account by the G. P. tests
of purity. The authors therefore suggest the following alkalimetric test
for inclusion in the G. P. tests of purity of magnesia usta: "0.5 Gm. of the
calcined magnesia is heated with 30 Cc. of \( \frac{\pi}{2} \) hydrochloric acid and about
20 Cc. of water until solution is effected, a few drops of methyl orange
solution added, and the liquid titrated with \( \frac{\pi}{4} \) KOH, of which not more
than 7.1 Cc. should be required to produce a yellow-red color." This
indicates a content of 92.5 per cent. of magnesium oxide—any calcium
oxide and calcium or magnesium carbonate present being calculated and

17
included as magnesium oxide. This requirement can easily be complied with by the manufacturer, and maintained by the pharmacist by proper methods of preservation.—Apoth. Ztg., xxiv (1909), No. 73, 679–680.

"Cork Metal"—Identification as Magnesium.—At one of the recent aeronautical exhibitions samples of a metal were shown under the name of "cork metal," which was said to be 40 per cent. lighter than aluminum, and to have numerous other properties which should make it a rival of the latter. Great secrecy was maintained as to the nature of this wonderful metal, but its properties were such as to cause F. J. Willott to submit it to chemical analysis. In appearance the metal resembles very strongly the alloys known as magnalium. The surface presents a lusterless whitish-gray color, both sheets and bars showing the scorings and scratches so frequently found on badly rolled or drawn aluminum. Careful analysis gave the following result: Aluminum, 0.04; iron, 0.017; zinc, 0.48; sodium, 0.21; magnesium, 99.30 per cent. It will be seen, therefore, that essentially, "cork metal" is nothing but magnesium, to which a small amount of zinc has been added. Whether this latter has been purposely introduced or, as is more probable, is merely present as an impurity, the author cannot say. As the metal evolves hydrogen when immersed in water it was found necessary to use organic solvents for the determination of the specific gravity. In alcohol this was found to be 1.762, thus confirming the conclusion that cork metal is in fact magnesium.—Chem. News, Oct. 1, 1909, 162.

Electron—A Magnesium Alloy Lighter than Aluminum.—The following statements concerning the new metal "Electron," which although of lighter specific gravity than aluminum is much stronger, is given in "Prometheus": The new metal is a magnesium alloy of a silver-white color, which may be moulded, pressed, rolled, drawn and polished, but oxidizes rapidly on exposure to the air. Its specific gravity fluctuates between 1.75 and 2.0 (aluminum = 2.7 to 3.0). The melted and cast metal has a tensile strength of about 18 Kgm. to the square millimeter with about 5 per cent. of ductility, but by mechanical processes of condensation, such as pressure, rolling, drawing, etc., the tensile strength of the metal may be increased to about 35 Kgm. to the square millimeter and the ductility to 18 per cent. without appreciably raising the specific gravity. Further investigations of the specific properties of this interesting alloy are in progress.—Pharm. Ztg., liv (1909), No. 98, 968.

EARTHS.

Group of Rare Earths—Review of Researches to Identify its Members. —Dr. G. Urbain briefly reviews the researches which have engaged his attention during the part fifteen years and were undertaken with the object of identifying the individual members of the group of rare earth metals, which, in accordance with the advance made since Sir William Crookes's
admirable researches preceding this period, are now recognized. These consist of the elements mentioned below in the order of the solubilities of their salts, by means of which they may be separated from each other for identification. The chief obstacle in the separation of the rare earth is isomorphism: but this isomorphism has proven useful, in as much as bismuth, though not belonging to the rare earths, comes between samarium and europium as regards the solubility of its salts which are isomorphous with the corresponding salts of the rare earths, and bismuth thus acts as a separating element. This fact seems to the author to point to a great natural law relating to the solubility of the elements of the same series. He has frequently observed that whatever the method of crystallization employed, the rare earths arrange themselves in the same order. Moreover, if yttrium is excepted, this is also the order of increasing atomic weight, as shown in the following table arranged in the order of solubilities:

The principal results which the author has contributed to the chemistry of these rare earths are summarized thus: The discovery of two elements, lutecium and neoytterbium, and the complete description of four others, europium, gadolinium, terbium, and dysprosium. Although the author’s conclusions are diametrically opposed to those of Sir William Crookes, to whose attainments he wishes to testify, his experiments have for the most part confirmed the results obtained by Sir William Crookes, and by them the chemistry of the rare earths has gained in simplicity what it has lost in charm. The experiments which Dr. Urbain has briefly described, dwelling only on the main principles, have led him to the following conclusions:

I. The elements S of Sir William Crookes, Z; and Z of M. Lecoq de Boisbaudran, are actually identical with Demarçay’s europium. This element possesses an emission spectrum, an absorption spectrum, a phosphorescence spectrum (which appears only when the derivatives of
europium are mixed in suitable diluents). The atomic weight of europium is $\text{Eu} = 152.0$.

II. The element victorium of Sir William Crookes is identical with gadolinium. This element also exhibits the three sorts of spectra. The atomic weight is $\text{Gd} = 157.3$.

III. The elements $\Gamma$ of Demarçay, $Z^3$ and $Z^5$ of Lecoq de Boisbaudran, $G^\beta$, ionium, and incognitum of Sir William Crookes, are identical with terbium, the existence of which was foretold by Mosander, although it was not isolated and described till sixty years later. Its atomic weight is $\text{Tb} = 159.2$.

IV. The elements $\Delta$ of Demarçay, $Z^\alpha$ and $Z^\gamma$ of Lecoq de Boisbaudran, $G^\delta$ of Sir William Crookes, $X_2$ of Exner and Haschek, are identical with Lecoq de Boisbaudran's dysprosium. The atomic weight is $\text{Dy} = 162.5$.

V. Marignac's ytterbium is a mixture of at least two elements. The atomic weight of one is about 174, and it has been defined by this and by a line and a band spectrum. This is $\text{lutecium}$. The residue of the old ytterbium the author calls $\text{neoytterbium}$. Its atomic weight has not yet been obtained constant; the mean atomic weight, however, is 172; but the author has observed such variations in its band spectrum that he is inclined to think that it is itself a mixture of two elements.—Chem. News, Aug. 13, 1909, 73-75.

**Rare Earths—Magneto-Chemical Analysis.**—G. Urbain says that in order to control the progress of the separation of the rare earths it is necessary to employ a property which varies in different terms more than the atomic weight. The coefficient of magnetization is such a property, and may conveniently be used for the purpose. Curie and Cheneveau's magnetic balance is a suitable instrument for taking the measurements, and either solutions or solid salts may be used. With an earth containing dysprosium and yttrium, for instance, it is easy to calculate the magnetization corresponding to each value of the atomic weight, and then to compare the theoretical curve with the experimental curve. The author has thus detected holmium and erbium in an earth containing yttrium and dysprosium. Thus, this method applied to the intermediate fractions obtained in the separation of two substances reveals the presence of another element which could not be detected by examining the spectrum.—Chem. News, June 10, 1910, 276; from Compt. rend., 150 (1910), No. 15.

**Rare Earths—Six New Elements.**—In the course of an address before the recent convention of German chemists, Prof. Muthmann mentioned that Dr. Auer v. Welsbach has succeeded in splitting up terbium and thulium each into two distinct elements, and the rare earth-metals, dysprosium and gadolinium, each into three distinct elements, thus increasing the number of elements of the rare-earth group from 16 to 22. Dr. v. Welsbach has proposed the names "aldebaranum" and "cassiopeium" for two of these new elements, for which, however, the names proposed by
Urbain—"lutecium" and "neoytterbium"—appear to be accepted. The two investigators had independent of each other, but at the same time, succeeded in separating these two elements from ytterbium (see Proceedings, 1909, 265).—Pharm. Ztg., Iv (1910), No. 47, 480.

**Bromates of the Rare Earths—Preparation.**—As the new method for the separation of the yttrium earths recently proposed depends on the fractional crystallization of the bromates, and has given excellent results, C. James and W. F. Langelier have prepared and investigated some of the bromates of the rare earths. These are usually prepared either by dissolving the oxide of the element in bromic acid, or by the metathesis of the sulphate of the metal with barium bromate. The latter is the preferable method, since barium bromate is soluble in about 130 parts of cold water, and its solubility decreases enormously in the presence of the very soluble bromates. Thus we can employ an excess of barium bromate, and very readily obtain pure bromates by crystallization. Because the rare-earth sulphate solutions deposit crystals on heating, it is best to cover the barium bromate with water, heat upon the water bath, and add gradually, with plenty of stirring, the sulphate of the desired element. Under these conditions no difficulties are encountered, and the barium sulphate filters (off) well. The authors have in this way prepared and described the following rare-earth bromates: **Lanthanum bromate**, \( \text{La}_2(\text{BrO}_3)_6 \cdot 18\text{H}_2\text{O} \); **Ceric bromate**, \( \text{Ce}(\text{BrO}_3)_4 \); **Praseodymium bromate**, \( \text{Pr}_2(\text{BrO}_3)_6 \cdot 18\text{H}_2\text{O} \); **Neodymium bromate**, \( \text{Nd}_2(\text{BrO}_3)_6 \cdot 18\text{H}_2\text{O} \); **Samarium bromate**, \( \text{Sm}_2(\text{BrO}_3)_6 \cdot 18\text{H}_2\text{O} \); **Yttrium bromate**, \( \text{Y}_2(\text{BrO}_3)_6 \cdot 18\text{H}_2\text{O} \). The andydrous salts of these members of the Cerium group of rare earths are obtained by heating to 150°C., with the exception of the prasemydium salt, which should not be heated above 130°C.—Chem. News, Aug. 20, 1909, 85–86.

**Polonium—Heat Generated by its Salts.**—William Duane has found that the heat generated by a salt of polonium amounts to 0.0117 cal. per hour. The ionisation produced by a polonium salt can be compared with that produced by a known amount of radium under the same conditions, and when this is done it is found that polonium and radium in quantities which give the same ionisation currents set free almost the same amounts of heat. This agrees with the hypothesis that the heat disengaged by these substances is due to the kinetic energy of the a-rays.—Chem. News, Aug. 13, 1809, 84; from Compt. rend. 128 (1909), No. 25.

**Polonium—Successful Production of Helium from it.**—It is known that among the new strongly radio-active substances polonium was the first to be discovered. Mme. P. Curie and A. Debiene say that many efforts have been made to isolate this substance and to characterize it as a chemical element, but notwithstanding the great activity of the products obtained, the result has not so far been obtained. The theory of radio-active transformation foresees that the quantity of polonium present in
radio-active minerals must be very small. According to this theory, polonium is considered as a descendant of radium, and the relative proportion of these substances in the state of radio-active equilibrium is equal to the ratio of their mean lives. The mean life of radium being about 5300 times greater than that of polonium, and radium being found in pitchblende in the proportion of about 0.2 Gm. per ton, it is evident that the same mineral cannot contain more than about 0.04 Mgm. of polonium per ton. Polonium is an unstable element which appears to represent the last radio-active terms in the series of radio-active derivatives. Giving rise to emission of α-rays, it should produce helium, but this production has not been observed up to the present, and it is important to know if there is really in this a fact incompatible with theory. To throw further light upon this the authors have undertaken a chemical investigation with a view to preparing polonium in a very concentrated state, using several tons of uranium residues for the purpose, and by methods indicated in their present communication they have succeeded in obtaining about 2 Mgms. of a highly concentrated material. The activity of this was measured by the electric method, and by calculation they proved that the quantity of polonium would amount to about 0.1 Mgm. and this amount is what should be found, according to theory, in about two tons of pitchblende. But the significant outcome of the present investigation is that the authors have demonstrated that helium is actually produced from a solution of polonium introduced into a quartz tube placed into an apparatus which could be freed from air completely. Much gas was disengaged, which was almost completely absorbed by the action of heated copper and copper oxide, potassium hydroxide, and phosphoric anhydride, leaving finally a residue of helium in a comparatively pure state, whose complete spectrum was observed and its volume measured. This volume is almost that required by theory.—Pharm. Journ. and Pharmacist, March 5, 1910, 292; from Compt. rend.

Radium Emanation—Conditions Facilitating its Liberation.—H. Herchfinkel finds that the liberation of radium emanation can be greatly facilitated by diluting the radium with the rare earths, which set free the emanations of thorium and actinium. Using the hydrates of didymium, iron, uranium, thorium, aluminum, barium, the fluorides and oxalates of barium and didymium, chromates of barium and iron, sulphates of barium and lead, and determining the emanation set free, the author has shown that the hydrates of iron and aluminum carry down nearly all the radium, while the other hydrates only carry down very little. All the hydrates set free a fairly large proportion of emanation in the dry state. The amount liberated by salts of barium is very small, and does not usually depend on the nature of the radical. Didymium fluoride and iron chromate set free a large proportion, didymium oxalate less, and lead sulphate still less.—Chem. News, Oct. 8, 1909, 184; from Compt. rend, 149 (1909), No. 4.
METALLIC ALUMINUM.

Radium Emanation—Action upon the Elements of the Carbon Group.—In continuation of previous studies dealing with the action of radium emanation on the elements of the carbon group, Sir William Ramsay and Francis L. Usher give a description of the methods employed in the experiments by which they have obtained the results described at the time. From the figures given it is shown that the elements of the carbon group, without exception, give carbon compounds when the emanation acts upon them; the amounts produced, however, are not all the same. It is not improbable that those elements which have a high atomic weight are generally more easily split up than those with lower atomic weights, but it must be supposed that lead is specially stable, and shows but little tendency to change into carbon.—Chem. News, Oct. 29, 1909, 209; from Berichte 42, 2930.

Radio-Active Substances—Comparison of the a-Rays Produced by Different Substances.—Mlle. Blanquies observes that it is generally supposed that the $\alpha$-particles emitted by different substances only differ in the velocity of their projection. If this is so, all $\alpha$-particles ought to have the same properties if they are studied when at the same distance from the end of their path. In order to verify this the author has determined the shape of the ionisation curve in which the ionisation is expressed as a function of the distance; if the hypothesis is correct all the curves constructed on the same scale should be superposable. Using polonium, radium C, and actinium B the author finds that the curves of the two former agree very well, while that of actinium B is different. The difference can be satisfactorily explained by supposing that all $\alpha$-particles are identical, except as regards velocity of projection, but that the radiation obtained by using as source a plate rendered active by contact with actinium emanation is complex. The experimental investigation of this hypothesis does not perfectly confirm it, but, on the other hand, the curves are not known with absolute certainty, so that complete agreement cannot be expected.—Chem. News, Sept. 24, 1909, 160; from Compt. rend., 148 (1909), No. 26.

Metallic Aluminum—Rapid Method of Determination.—E. Kohn-Abrest finds that when metallic aluminum is heated to about 300° C, first in a current of hydrogen and then in a current of hydrochloric acid gas, a residue is left consisting of aluminum oxide, iron, chlorine, and different impurities, while a sublimate of aluminum chloride is obtained, containing very small proportions of iron perchloride and traces of ammonium chloride due to the decomposition of ammonium nitrate by the hydrochloric acid. Any silicon is volatilized and carried away by the current of gas in the form of silicochloroform. If the chloride is determined in the aluminum chloride the amount of metallic aluminum is obtained directly. Special precautions have to be taken in the condensation of the vapors and their solution in water. This method enables very rapid determina-
tions to be made of metallic aluminum and the oxide. By also estimating the silicon and the iron a complete analysis of the commercial metal can be made.—Chem. News, Oct. 22, 1909, 207; from Compt. rend., 149 (1909), No. 6.

**Aluminum Nitride—New Process of Preparation.**—According to A. J. Sofianopoulos, aluminum nitride (Al₃N₃) may be obtained by the following new process: A stream of pure dry ammonia is passed over powdered aluminum at a red heat until the gas ceases to be absorbed and hydrogen is no longer produced. The nitride produced in this way is an amorphous, spongy product of a grey color, absolutely pure when prepared from pure products. If it should be mixed with a small quantity of metallic aluminum, it may be purified by reducing it to a very fine powder and treating it with heated mercury, which forms an amalgam with the aluminum without in any way affecting the nitride. The nitride is then easily separated by washing with cold water and decanting. It is quite stable in the dry state, and is not attacked by oxygen, even when heated in an atmosphere of that gas. It is easily decomposed however, by the halogens, with production of nitrogen and the corresponding salts of aluminum. Acids decompose it in the cold. At ordinary temperatures it is decomposed by water slowly, more quickly at 60° C., and very rapidly at boiling temperatures, the products being ammonia and aluminum hydroxide. With caustic alkalies, especially on boiling, there is abundant production of ammonia and the formation of the corresponding aluminate.—Pharm. Journ and Pharmacist, July 31, 1909, 134; from Bull. Soc. Chim., 1909, 614.

**Exsiccated Alum—Moisture Absorbed on Exposure.**—Willard Graham records the results of experiments made to ascertain the amount of water that may be absorbed by dried alum on exposure to air, and gives figures which show that under circumstances this may amount to as much as 45 per cent.—thus exceeding the amount lost by ordinary powdered alum when dried for 8 hours at 160° C., which was only between 39 and 40 per cent. If kept in well-stoppered bottles, the amount of water absorbed will (of course) be much less than when exposed to the air, but even under the best conditions, exsiccated alum will absorb considerable moisture. The author is of the opinion that the Pharmacopœia (which requires exsiccated alum to contain 99 per cent. of anhydrous salt) should allow the presence of from 5 to 10 per cent. of water.—Proc. Penna. Pharm. Assoc. 1909, 182–184.

**Sodium Alum—Preparation and Properties.**—W. R. Smith says that the existence of sodium alum, Na₃SO₄Al₂(SO₄)₃·24H₂O, has been denied by Ostwald among others. He finds, however, that whenever approximately equivalent amounts of sodium and aluminum sulphates are dissolved in water and made to crystallize at ordinary temperatures, octahedral crys-
Cdalmium. 265
tals are obtained which correspond in composition with the theoretical
sodium alum. The best method of manufacturing this compound is to
dissolve the materials in an amount of water sufficient to give a solution
moderately supersaturated at ordinary temperatures, and then cool the
solution and induce crystallization by stirring or seeding. Small crystals
will be obtained similar to "alum meal." If larger crystals are desired,
they can be made by slow evaporation at ordinary temperatures. That
this substance is a definite chemical species is proved by the fact that the
composition does not vary when crystallized from solutions of varying
composition. The reason why the existence of sodium alum has been
questioned probably lies in the fact that it is not formed at temperatures
much above 30° C.—Pharm. Journ. and Pharmacist, Sept. 4, 1909, 319;

Zinc—New Reaction.—Angel del Lampo Cerdan finds that if ammonia
is added to the solution of a zinc salt, until the precipitate formed is re-
dissolved, the addition of an alcoholic or ethereal solution of resorcinol
develops a handsome blue color, which manifests itself quicker or slower
according to the quantity of zinc salt present. The reaction is available
for dilution of 0.01 Zn in 1000 Cc. of water, but is interfered with by the
presence of cobalt, nickel, copper and magnesium.—Pharm. Ztg., lv
(1910), No. 12, 118; from Rép. de Pharm., 1910, No. 1.

Zinc Peroxide—Variable Quality in French Commerce.—P. Lemaire
observes that zinc peroxide, which is considerably prescribed in Continen-
tnal medical practice, is very variable in French commerce. Of
fifteen samples examined, the worst contained only 11.15 per cent. of
ZnO₂, and the best but 40.9 per cent., only two other samples giving more
than 40 per cent. While the author did not come across a sample which
contained no available oxygen, he mentions that Vauverts has met with
some samples which were simply ordinary zinc oxide. The peroxide is
tested by dissolving 20 Cgm. of the sample in 10 Cc. of 10 per cent. sul-
phuric acid and titrating the solution with \( \frac{V}{10} \) permanganate, each Cc. of
which is equivalent to 2.45 per cent. of ZnO₂ in the sample.—Pharm.
Journ. and Pharmacist, April 2, 1910, 429; from Répert. de Pharm., 22
(1910), 1.

Cadmium—Insecticidal Properties of its Solutions.—H. C. Dunning
directs attention to the value of a solution of cadmium nitrate as an in-
secticide. The solution was made by dissolving 5 parts of cadmium metal
in 15 parts of C. P. nitric acid and 80 parts of filtered water, and this was
used as a spraying insecticide by further dilution with 20 parts more of
water. His experience demonstrates that it rapidly kills red ants, roaches,
army worms and potato bugs, when sprayed with this solution. In fact,
“it seems to be death to every species of animal life from the smallest bacteria to rats.” Mr. Dunning also attributes pronounced therapeutic value to this solution, particularly as a germicide in the treatment of tuberculosis. He has found that when freshly made and the vapor (spray?) of the solution was inhaled for one minute, a cold in the head was cured within one hour.—Proc. Penna. Pharm. Assoc., 1909, 240–242.

CHROMIUM.

Chromyl Sub-Chloride—Formation and Properties.—According to T. Pascal, nitric oxide acts on chromyl chloride to give a sub-chloride of chromyl, \(5\text{CrO}_2\text{Cl}_2 + 4\text{NO} = (\text{CrO}_2)_3\text{Cl}_6 + 4\text{NOCl}\). This compound forms crystals which have magnetic properties. They deliquesce in damp air, and dissolve readily in water, giving chromic acid, hydrochloric acid, and salts of chromium. At a high temperature they decompose according to the equation \(3(\text{CrO}_2)_3\text{Cl}_6 = 5(\text{CrO}_2)_2\text{Cl}_4 + 8\text{Cl}\), while, when gently heated, the reaction which occurs is \((\text{CrO}_2)_3\text{Cl}_6 = (\text{CrO}_2)_2\text{Cl}_4 + 2\text{CrO}_2\text{Cl}_2\). It may be said that at a relatively low temperature the subchloride’s reactions are due to its chloride, and at a high temperature to both its oxygen and chlorine.—Chem. News, July 16, 1909, 36; from Compt. rend., 148 (1909), No. 22.

MANGANESE.

Permanganate of Potassium—Danger of Intravenous Injection in Snake Bite.—Sir Lauder Brunton’s experiments, and other experiments made at Bombay and Calcutta, confirm the results obtained by Sir Joseph Frayrer over 30 years ago, that intravenous injection of potassium permanganate in the treatment of snake bite are both useless and dangerous. But these tests have nothing to do with the local application of the salt, by incision and direct application of the permanganate at the seat of the injection of the venom—a number of successful applications, as well as a few unsuccessful ones having been recorded.—Pharm. Journ. and Pharmacist, June 18, 1910, 758.

TUNGSTEN.

Phospho-tungstic Acid—A Sensitive Reagent for Ferrous Salts.—A. Richaud and Bidot recommend phosphotungstic acid as a sensitive reagent for ferrous salts. The reagent is prepared by dividing 25 Gm. of sodium phosphotungstate in 250 Gm. of water and adding 5 Gm. of hydrochloric acid. If some of this reagent and a little NaOH solution are added to solutions containing mere traces of a ferrous salt, a blue color results, and disappears again on acidulating the mixture. This reagent is particularly recommended for the detection of traces of iron in urine.—Pharm. Ztg. lv (1910), No. 43, 436; from Merck’s Annual Rep., April, 1910.

Uranyl Chloride—Preparation and Properties.—(Echsner de Coninck states that uranyl chloride may be obtained by adding drop by drop a so-
olution of barium chloride to a concentrated freshly prepared aqueous solution of uranic sulphate: \( \text{SO}_4(\text{UO}_2) + \text{BaCl}_2 = \text{BaSO}_4 + \text{UO}_2\text{Cl}_2 \). The compound is deliquescent and dissolves in water. When reduced by hydrogen it yields HCl and UO₂. When heated with a large excess of caustic potash in an open tube a peruranate is formed: \( \text{UO}_2\text{Cl}_2 + 2\text{K}_2\text{O} + O = 2\text{KCl} + \text{UO}_3\text{K}_2 \). With barium chloride and ammonia it yields barium uranate: \( \text{UO}_2\text{Cl}_2 + \text{BaCl}_2 + 4\text{NH}_3 + 2\text{H}_2\text{O} = 4\text{NH}_4\text{Cl} + \text{UO}_2\text{Ba} \).—Chem. News, Sept. 24, 1909, 160; from Compt. rend., 148 (1909), No. 26.

URANIUM.

Uranium Oxides — Preparation from the Sulphate.—Echsnner de Coninck obtained various uranium oxides indirectly from the sulphate as follows: The uranic sulphate was transformed into nitrate by treating a dilute aqueous solution of it with neutral barium nitrate until all the barium sulphate had been precipitated. The liquid was then concentrated and evaporated to dryness, when the light yellow uranic hydrate, \( \text{UO}_2\cdot2\text{H}_2\text{O} \), was deposited, mixed with a very minute amount of orange-yellow monohydrate, \( \text{UO}_3\cdot\text{H}_2\text{O} \). From a mixture of uranoxy and uranic sulphates, uranic dihydrate and uranoxy monohydrate \( \text{UO}_3\cdot\text{H}_2\text{O} \) were obtained. The latter oxidizes spontaneously in air, as shown by the equation \( \text{UO}_2\cdot\text{H}_2\text{O} + O = \text{UO}_3\cdot\text{H}_2\text{O} \).—Chem. News, July 16, 1909, 36; from Compt. rend., 148 (1909), No. 22.

IRON.

Iron Group of Metals—Sensitive Microchemical Reactions.—N. Schoorl describes a number of microchemical reactions for metals of the iron group as follows:

Cobalt.—A sensitive reagent may be prepared by mixing equal volumes of saturated solutions of ammonium sulpho-cyanide and mercuric chloride. A trace of this is applied by means of a platinum wire to a drop of the cobalt solution on a micro-slip. After standing a minute or two the deep blue precipitate of mercury-cobalt sulphocyanide forms irregular triangular particles. By this test one millionth part of a milligramme of cobalt may be detected sub lente.

Nickel.—Dimethylglyoxime is the most sensitive reagent for nickel in the presence of ammonia. A select precipitate is formed which, under the microscope, appears as very handsome bundles of needles. By this micro-test the presence of nickel (1 in cobalt, 5,000) may be detected.

Iron.—The precipitation of Prussian blue under the microscope affords the most sensitive reaction for iron.

Aluminum.—The formation of characteristic alum crystals on addition of acid potassium sulphate is characteristic of aluminum.

Chromium.—The precipitate of benzidine chromate affords the most sensitive micro-reaction for chromium. A reagent is prepared with benzi-

**Ferrum Reductum—Improved Process of Assay.**—Virgil Coblentz and Otto B. May observe that the present "iodine method" of assay for reduced iron, essentially that of the German, Austrian, and Norwegian Pharmacopoeias, was considered at the time of the last revision satisfactory in procedure and accurate in results. The experiments were carried out upon samples which were of a very uniform degree of fineness, a condition which contributed to securing uniformity of results. Attention has recently been called by G. Frerichs to the discrepant results obtained by this method to samples of reduced iron found in the foreign market, who attributes these discrepancies to insolubility of iron, due to physical differences; perhaps greater density, and who found a modification of the "sulphate of copper method" of assay to yield more satisfactory results. The authors have experimented with this method, as modified by Frerichs, and also with the methods as modified by Andrews, and give analytical data which confirm the reliability of these methods. They have, however, also experimented with a method in use at the Edgar Thomson Steel Works, suggested for trial by the chief chemist as their "Citric Acid Method," and find this to give admirable results, while the method appears to be free from some of the objectionable features of the "copper methods." It is carried out as follows: "Place 170 Cc. of nearly saturated solution of double chloride of copper and potassium and 5 Gm. of citric acid in an Erlenmeyer flask. Add 3 Gm. of the sample and shake until dissolved, keeping the temperature below 60° F. Filter residue on 11 Cm. paper, and wash with cold water and a little citric acid until free from copper. Wash well with hot water, ignite, and weigh as iron oxide." This residue consists of iron oxides as well as silica. In two experiments recorded the residues from the same sample amounted to 2.38 and 2.31 per cent. respectively, indicating 97.62 and 97.69 per cent.—the gravimetric CuSO₄ method having given 97.62 and 97.92 per cent. respectively.—Merck's Rep., July, 1909, 165–167.

**Ferrites and Iron Oxides—Magnetic Properties.**—From an exhaustive study of the magnetic properties of ferrites and iron oxides, Siegfried Hilpert concludes that in the series of the ferromagnetic iron oxide compounds the chemical causes of the appearance of magnetic properties depends only on the acid function of the iron oxide. Conversely, however, the acid character of the iron oxide does not in all cases produce ferromagnetic properties. Feebly magnetic ferrites must be heated to high temperature before they exhibit magnetic properties. In the case of all the ferrites investigated it was possible to produce a magnetic modifica-
tion. Moreover, all ferrites have the property which is common to the ferromagnetic metals of possessing transition temperatures above which the magnetic properties entirely disappear. These changes are generally reversible. The change of black ferroso-ferric oxide into red iron oxide occurs without appreciable change in the magnetic properties, and apparently in this case there is no connection between the absorption of light and also the electrical conductivity and the magnetic properties. Chem. News, Aug. 27, 1909; from Rev. d. Chem. Ges., 242 (1909), No. 10.

Calcium Ferrites—Formation and Properties.—Siegfried Hilpert and Ernst Kohlmeyer state that when iron oxide prepared from oxalate and pure calcium oxide are fused together, and the melting-point curve of the mixture is examined, it is found that the melt with 95 per cent. of lime contains the latter in the form of crystals, which decrease in amount as the proportion of iron increases, until they disappear at 75 per cent. of lime. At 1410° calcium orthoferrite 3 CaO·Fe₂O₃ is formed. When the percentage of lime has been decreased to 60 a maximum corresponding to 3CaO·2Fe₂O₃ is observed, and as the proportion of iron is increased a eutectic occurs at 1200° C. corresponding to CaO·Fe₂O₃. The color of the melts varies with the amount of lime present, those richest in iron oxide being black and metallic-looking. Their conductivity is small. The calcium ferrites are attacked by water and dilute acids. Chem. News, Febr. 25, 1910, 96; from Ber. d. D. Chem. Ges., 42 (1909), No. 17.

NICKEL.

Nickel and Cobalt—Differentiation as Ferrocyanide.—Franz Felix Werner calls attention to the possible utility in the analytical scheme, of the characteristic reactions of cobalt and nickel with ferrocyanides. Potassium ferrocyanide gives with solutions of cobalt salts, even when dilute, a characteristic dark green precipitate of cobalt ferrocyanide, and in very dilute solutions a distinct green color is perceptible. With nickel salts, an apple-green precipitate is produced under the same conditions and the resulting ferrocyanide is quite stable, and quantitatively correct, whereas the cobalt ferrocyanide is easily oxidized and very unstable. For the present these reactions are available in qualitative analysis: The portion of ammonium sulphide precipitate remaining undissolved by HCl is dissolved in that acid by the aid of a few drops of HNO₃, in the well known manner, the solution evaporated, the residue dissolved in dilute HCl, and the solution tested with ferrocyanide, which reveals the presence of Co and Ni by the reaction described.—Pharm. Ztg., lv (1910), No. 21, 210.

Nickel and Copper—Their Alloys not Definite Compounds.—Em. Vigouroux reports the results of an experimental inquiry into the constitution of alloys of nickel and copper. The pure metals copper and nickel were intimately mixed and fused, and the masses thus formed were ex-
amined both chemically and physically to ascertain whether compounds had been produced. The substances isolated by chemical reactions contained the two metals in proportions which depended only on the experimental conditions, which argues against the formation of definite compounds. This result is confirmed by the determination of the electromotive force of the alloys.—Chem. News, Febr. 18, 1910, 83; from Compt. rend., 149 (1909), No. 26.

INDIUM.

Indium—Quantitative Determination.—According to A. Thiel and H. Koelsch, indium may be determined quantitatively by precipitating it as hydroxide with ammonia, and heating to 850° C., in an electric furnace. It is then obtained in the form of oxide, In₂O₃. The precipitate must be heated in a Gooch's crucible. If the oxide is too strongly heated a loss of weight is observed. This is not because it volatilizes as such, but it gives up oxygen, forming a lower oxide which crystallizes in the regular system. Indium hydroxide is appreciably soluble in ammonia, complex compounds being formed. The solubility of freshly precipitated indium hydroxide in strong ammonia can be used to separate indium from iron. When indium hydroxide is washed with pure water colloidal solutions are formed, and also when ammonia and dimethylamine are used to wash it, provided that the salts of the two last named substances are not present in concentrated solution. Hitherto InI₃ has been the only iodium iodide known, but the authors have proved the existence of two other iodides, InI₂ and InI. They have also prepared a monosulphide, InS, di-indium triselenide, In₂Se₃, and indium monotelluride, InTe. Lower tellurides and selenides appear to exist, as well as a monophosphide, InP.—Chem. News, June 3, 1910, 264; from Ztschr. Anorgan. Chemie, 66 (1910), No. 3.

LEAD.

Lead Chromate—Coloring Power on Textiles.—According to L'io Vignon, precipitated lead chromate dyes silk, wool, and cotton equally well, differing from the soluble dyes—orange II, picric acid, and roceline—as regards the conditions of fixation. To obtain a given shade much more lead chromate than soluble dye is necessary. Moreover, lead chromate is not fixed chemically by textiles, but its fixation is evidently due to molecular attraction.—Chem. News, July 2, 1909, 12; from Compt. rend., 148 (1909), No. 20.

Lead Phosphates—Preparation and Properties.—H. Alders and A. Stähler have studied the properties of primary-, secondary- and tertiary lead phosphates. They find that tertiary lead phosphate, Pb₃(PO₄)₂, prepared by the action of excess of alkali phosphate on a soluble lead salt always contains alkali which cannot be removed by boiling with water. In order to get the pure tertiary salt, excess of lead acetate must be boiled.
with a little sodium phosphate, or the secondary salt must be boiled for a long time with water, when it is converted into the tertiary phosphate. Secondary lead phosphate, PbHPO$_4$, can be very easily prepared by adding hot dilute phosphoric acid (about 25 per cent. H$_3$PO$_4$) to boiling dilute lead nitrate solution. It then forms in fine crystals which can be re-crystallized in dilute phosphoric acid. Primary lead phosphate can be prepared by the action of excess of hot strong phosphoric acid on the secondary salt. The limits of stability of the secondary phosphate are the widest. The tertiary phosphate only exists when very little H$_3$PO$_4$ is present, and the primary when the H$_3$PO$_4$ concentration is very great. The latter changes very readily into the secondary phosphate when small changes of concentration occur.—Chem. News, Aug. 27, 1909, 107; from Ber. d. D. Chem. Ges., 42 (1909), No. 10.

Lead Sulphate—Solubility. — J. Schnal’s determination of the solubility of lead sulphates give numbers which differ considerably from those obtained by Fresenius and Rodwell. The purity of the salt is the only factor which can influence the solubility, the presence of a trace of sulphuric acid being sufficient to cause a considerable difference. Solution takes place extremely slowly, and possibly the lead sulphate decomposes according to the equation PbSO$_4$ + 2H$_2$O = PbOH$_2$ + H$_2$SO$_4$. The hydrated oxide of lead dissolves easily in sulphuric acid. Chem. News, July 9, 1909, 24; from Comp. rend., 148 (1909), No. 21.

Lead and Bismuth—Quantitative Separation. — After trying and abandoning various methods for the separation of lead and bismuth which proved unsatisfactory, J. C. Galetly and G. G. Henderson adopted the following method proposed by Clark (1890), which they modify in some particulars:—A solution of the chlorides of lead and bismuth containing a spiral of steel wire (1 to 2 grammes) was heated until most of the iron was dissolved, and the precipitated bismuth and the remainder of the iron were collected, washed with boiling water until free from lead, and dissolved in hydrochloric acid with the aid of potassium chlorate. After diluting the solution, the bismuth was precipitated as sulphide, the precipitate washed with a solution of hydrogen sulphide until free from iron, dissolved in nitric acid, and after filtration precipitated with ammonium carbonate. The precipitate was washed, ignited, and weighed as Bi$_2$O$_3$. The results obtained were much more satisfactory than those given by any other of the processes tried. The authors consider that Clark’s process for the estimation of bismuth in presence of lead is not only easily carried out, but that it is also capable of yielding accurate results. The process, however, can be improved by precipitating the bismuth as phosphate—a method which they have found to give excellent results—instead of with ammonium carbonate as originally described. Pharm. Journ. and Pharma. cist, Oct. 2, 1909, 423: from Analyst, Sept. 1909, 389.
Titanium—Production of the Pure Metal.—Until Moissian obtained metallic titanium free from nitrogen by reducing titanium dioxide and reheating the product, all attempts had resulted in the production of various nitrides, which from their metallic appearance were mistaken for the metal. M. A. Hunter now describes a method which is admirable for producing the metal in moderately large quantities in a state of purity hitherto unattained. It consists in the reduction of titanium tetrachloride with sodium, the reaction being conducted in a bomb of machine steel, containing 50 Gm. of titanium tetrachloride and 25 Gm. of sodium, and heating to a low red heat. The almost pure metal, outwardly resembling polished steel, is hard and brittle, and cannot be drawn into wire. It melts with difficulty between 1800° and 1850° C.—Journ. Amer. Chem. Soc., March, 1910, 330.

Titanium—New Reaction.—Jean Piccard finds that in reductions with titanium trichloride certain acids act as catalytic agents to accelerate the reaction, and it is found that, in general, monobasic acids have no action, while polybasic acids act as catalysts. Hence this reaction can be used as a test of the basicity of an acid. It is interesting to notice that hydrofluoric acid is very strongly active, which confirms the assumption of the polymerization of the acid to form H₂F₂ molecules. It is already known that the salts of trivalent titanium give with oxalic acid in aqueous solution a yellow coloration. Pyrocatechin also gives an orange-yellow coloration with titanium trichloride, and this color reaction is much more marked than that with oxalic acid. If the dilution is not too great, a red-brown amorphous precipitate is obtained, forming a black insoluble powder on drying, which appears to be a mixture of several compounds. If the dilution is greater, the formation of the yellow coloration is a very sensitive test for titanium, fifteen times as sensitive as the H₂O₂ reaction. The pyrocatechin must be present in excess, and mineral acids prevent the reaction, while alkalis, alkaline carbonates, or ammonia weaken it.—Chem. News, Jan. 21, 1910, 35; from Ber. d. D. Chem. Ges., 42 (1909), No. 16.

Titanium Chloride—Reduction by Hydrogen.—Hans Georges and Arthur Stähler find that titanium tetrachloride is reduced to the trichloride by hydrogen at temperatures ranging from 785–1200° C., the yield of TiCl₃ being increased as the temperature is raised, although the reaction is not quantitative even at 1200° C. TiCl₄ is a fine reddish violet powder which is rapidly decomposed by damp air. Even at the ordinary temperature it decomposes according to the equation 2TiCl₄ = TiCl₂ + TiCl₃. Solutions of titanium dichloride (divalent titanium) turn violet when heated in air or when treated with nitric acid, the color in the latter case disappearing. With TiCl₄ they give a violet coloration, and with ammonia, ammonium carbonate, or ammonium sulphide a brownish black precipitate. The
authors have also found that divalent titanium gives a green solution with potassium rhodanite, green titanous acetate with sodium acetate, and calomel with mercuric chloride. Chem. News, Oct. 29, 1909, 220; from Ber. d. Chem. Ges., 42 (1909), No. 13.

THORIUM.

Thorium Bromide and Chloride—Formation and Kind of Hydrates.—According to Ed. Chauvenet, the normal hydrate of thorium chloride, ThCl₂.8H₂O, is transformed into ThCl₂.4H₂O at 50°, and at the same temperature the hydrate of thorium bromide which contains 12 molecules of water, and which is obtained by evaporating Th(OH)₄, with HBr, yields ThOHBr₃.9H₂O. This last compound is analogous to ThOHCl₃H₂O which is formed at temperatures above 100° C. only. At 105° C. ThBr₃.12H₂O yields ThOBr₂₃.9H₂O and ThCl₂.8H₂O yields ThOCl₂ at 250° C. Thus the oxyhalogen derivatives of the bromide are formed at much lower temperatures than the corresponding derivatives of the chlorides. Chem. News, Oct. 8, 1909, 184; from Compt. rend., 149 (1909), No. 4.

Thorium Chlorophosphate—Formation and Composition.—According to A. Colani, a chlorophosphate of thorium of formula ₂P₂O₅.₃ThO₂.ThCl₂, and corresponding to the chlorophosphate of uranium, can be prepared by heating thorium metaphosphate and thorium chloride to a fairly high temperature in an atmosphere of carbon dioxide. Thorium bromide, when treated similarly, gives a bromophosphate of different formula, the analysis of which is very troublesome, and does not lead to satisfactory results. Double phosphates of calcium and strontium also exist, having the same formulæ as the corresponding compounds of uranium.—Chem. News, Oct. 8, 1909, 183; from Compt. rend., 149 (1909), No. 3.

COPPER.

Copper Sulphate—Gravimetric Estimation.—P. B. Dallimore finds the following gravimetric method for estimating copper in the sulphate to be rapid, clean, and reliable, giving perfectly concordant results and comparing favorably with the volumetric estimation—the method depending on the reduction of copper salts to metallic copper. Three Gm. of copper sulphate are gently heated over a water bath with an excess of hypophosphorous acid diluted with an equal volume of water, the mixture being constantly stirred. In a very few minutes the finely divided copper comes down, and the clear liquid will be found quite free from copper. The liquid is then decanted through a filter, the precipitate transferred to the filter with a jet of water, and carefully washed to remove all traces of acid. It is then washed with alcohol and ether, dried in a current of air a few moments, and transferred at once to a weighed porcelain crucible, in which it is converted to the oxide by heat, and ignited to constant weight. In an actual experiment, 3.085 Gm. of copper sulphate yielded 0.983 Gm. of
copper oxide, which figures correspond to 99.97 per cent. CuSO₄.5H₂O.—

Copper Sulphate — Efficiency as an Algicide.—According to Bulletin 76, Bureau of Plant Industry, U. S. Dept. Agriculture, ponds, pools, tanks, reservoirs, etc., may be freed from algae by the use of copper sulphate. The necessary amount of copper sulphate is put into a bag of coarse mesh and slowly dragged through the water. By a process of gradual solution, the water will become impregnated with the copper sulphate. In large ponds or reservoirs, this may be carried out by tying the bag of sulphate behind a boat and quietly rowing about; in smaller ponds or canals, the bag fixed to a pole can be dragged through the water by a man walking along the bank. The amount of copper sulphate required to completely destroy fresh-water algae is very small, but more is required in warm countries than in cool. When a sufficient amount of copper sulphate was used to give a strength of one part in 4,000,000 to 10,000,000, or say 1 lb. of copper sulphate dissolved in 1,000,000 gallons of water, it was found sufficient to destroy nearly all forms of green algae, and in most instances it does not injure the fish in the ponds.

MERCURY.

Mercury—Detection by Means of Metallic Aluminum.—C. Reichard directs attention to a new method for detecting mercury in solutions, which depends on the formation of a white coating of aluminum oxide on the surface of a bright sheet or wire of aluminum in contact with such a solution. The reaction is quite sensitive, but is directly available only if the mercury is in solution. Sparingly soluble mercury salts must therefore first be transformed into the soluble chloride. Moreover, the aluminum surface must be perfectly bright and free from fat, and the metal should therefore be cleansed with ether, and the mercury solution must be neutralized before attempting the test. The reaction must be allowed to take place perfectly undisturbed, while the observation is best made by allowing it to take place under a bell jar on a black surface.—Pharm. Zentralh., 57 (1910), No. 21, 443-449.

Mercury—Volumetric Method of Estimation in Galenical Preparations. —Referring to Rupp's application of the volumetric method of estimating mercury in galenical preparations, Dr. R. Ginter mentions that the proposed method when applied to ointments prepared with a gelatin base or starch base and containing only small percentages of mercury compound, requires some modification. As an example, he selects such an ointment containing about 0.3 per cent. of corrosive sublimate and conducts the process as follows: 45 Gm. of the ointment (containing about 1.125 Gm. of mercuric chloride) are mixed with 250 Cc. of distilled water in a 750-Cc. stoppered flask, shaken vigorously a few minutes, and after adding 5 Cc. of potassium iodide, again for 10 minutes. Then 50 Cc. of
10 per cent. NaOH solution and 25 Cc. of 40 per cent. formaldehyde solution are added, the mixture is again shaken 10 minutes, acidulated with 12 Cc. of glacial acetic acid, and then 15 Cc. of \( \frac{x}{10} \) iodine solution are added. After again shaking 10 minutes, the mixture is titrated with \( \frac{x}{10} \) thiosulphate solution, of which 5 Cc. should be required, showing that 10 Cc. of the iodine solution has been consumed. Accurate values are thus readily obtained. Pharm. Ztg., LV (1910), No. 42, 428.

Mercury—Convenient and Accurate Method of Determination in Ointments.—L. Willen regards the ordinary methods for the determination of the mercury in ointments, for example in the yellow oxide of mercury ointment, either to be inaccurate or when accurate to be too complicated, and suggests the following as being both convenient and accurate: A quantity of ointment containing about 0.1 Gm. HgO is carefully warmed in a 100-Cc. flask with 10.0 Cc. of benzin until it is dissolved; 15 Cc. of \( \frac{x}{10} \) iodine solution is then added, the flask well stoppered, and the warming of flask and contents continued for a short time to complete the reaction. The excess of iodine is then titrated with \( \frac{x}{10} \) sodium thiosulphate without the use of an indicator. By multiplying the number of Cc. of iodine solution consumed by 0.108, the HgO content of the ointment is ascertained.—Schweiz. Wschr. f. Chem. u. Pharm., xlviii (1910), No. 16, 250.

Mercuric Salts—Determination with Diphenylcarbazide.—Oddo finds that diphenylcarbazide yields with mercurous salts a mercurodiphenylcarbazone having a characteristic blue color which is not discharged by nitric acid, and applies the reaction practically as follows: The solution of mercurous salt—for example mercurous nitrate—is treated with \( \frac{x}{10} \) sodium chloride solution until all the mercury salt is precipitated as mercurous chloride. The end of the reaction is recognized when diphenylcarbazide no longer produces a blue color—this reagent being applied in the form of filter-paper saturated with an acetic-acid solution of the carbazide, which is touched from time to time with the end of a glass rod dipped into the solution under examination after the precipitate of mercurous chloride has subsided.—Pharm. Ztg., lv (1910), No. 43, 436; from Merck’s Annual Rep., April, 1910.

Mercurous Iodide—Preparation of an Impalpable Salt for Ointment.—Dr. v. Ammon gives explicit directions for preparing mercurous iodide in a minutely divided condition, in connection with a formula for a 1 per cent. ointment, as follows: 2.1 Gm. of mercurous nitrate are dissolved in 500 Cc. of cold distilled water, with careful trituration and continuous addition of the solvent. The solution is filtered and carefully and equably, poured into a solution of 1.32 Gm. potassium iodide in 250 Cc. of distilled water, heated to 50° C., and contained in a 1000-Cc. glass cylinder. A greenish turbidity manifests itself at first, changing gradually to yellowish.
The cylinder is then stoppered, and inverted several times, until the mercurous iodide settles to the bottom in form of an extremely fine light yellow coagulum, and finally precipitates completely. This precipitate, after careful washing with distilled water by decantation until the washings no longer give a blue color with diphenylamine and sulphuric acid, or a black color with KOH or NaOH solution, is reduced by further decantation until the residual magma, containing 2.5 Gm. of mercurous iodide, weighs exactly 13 Gm. In this form it is used for making a 1 per cent. ointment, "Ungt. hydrarg. jodatum pultiforme," which see under "Pharmacy." In a precisely analogous manner an impalpable form of

Mercuric Iodide (Hydrarg. bijodatum pultiforme) is prepared, using 1.2 Gm. of mercuric chloride; 300 Cc. dist. water; and 1.5 Gm. of potassium iodide; 400 Cc. dist. water, and the magma (containing 2 Gm. mercuric iodide) is converted into ointment in the same way as the preceding.—Pharm. Ztg., lv (1910), No. 19, 191; from Münch. Med. Wschr., 1910, No. 9.

Mercuric Chloride—Preparation by the Humid Method.—Prof. E. Rupp and W. Klee find it practicable to prepare corrosive sublimate by the humid method, which can be carried out economically as follows; 100 p. mercuric sulphate and 40 p. sodium chloride are finely powdered and converted into a magma with 20 p. of 5 per cent. hydrochloric acid. After standing 24 hours with frequent stirring, the mixture is triturated and then extracted with boiling 95 per cent. alcohol. If this extraction is done with the aid of a reflux condenser, keeping the liquid boiling, the corrosive sublimate formed is completely extracted with the use of a minimum quantity of alcohol within 1 to 1½ hours. On distilling off the alcohol and recrystallizing the residue from boiling water, the mercuric chloride is obtained in form of dazzling white needles, amounting to 90 per cent., perfectly free from sulphuric acid and conforming to the requirements of the G. P. Instead of mercuric sulphate, the nitrate may be used in same way but is more expensive.—Apoth. Ztg., xxv (1910), No. 26, 219.

Corrosive Sublimate—Volumetric Estimation.—Prof. E. Rupp recommends the volumetric estimation of corrosive sublimate by a method based upon the conversion of mercuric chloride into cyanide, which results quantitatively by reacting with alkali cyanides in excess. The reaction occurs according to the equation: $\text{HgCl}_2 + 2 \text{KCN} = \text{Hg(CN)}_2 + 2\text{KCl}$. By using a known excess of cyanide, this excess may be ascertained by titration with hydrochloric acid, using methyl orange, which is not affected by hydrocyanic acid, as indicator—this reaction being explained by the following equation: $\text{KCN} + \text{HCl} = \text{KCl} + \text{HCN}$. The author gives the details of the method, as applied to the assay of corrosive sublimate pastilles for which it is particularly adapted.—Apoth. Ztg., xxiv (1909), No. 100, 939.
**New Double Arsenates.**

**Dimercury-Ammonium Bromide—Formation and Properties.** — H. Gaudechon states that when a hot solution of HgBr₂ is added to a cold solution of ammonia a white precipitate of NH₄Br·3NH₄Br or a yellow precipitate of NH₄Br·NH₄Br is obtained according to the concentration. When either of these is washed with water, NH₄Br·H₂O is obtained. If, however, the ammonia solution is added to the hot HgBr₂ solution, a precipitate is formed, which on washing does not give NH₄Br·H₂O. This precipitate appears to be a compound (NH₄Br)₂HgBr₂ analogous to (NH₄Cl)₂HgCl₂. From this NH₄Br is obtained by treatment with ammonia. It is a yellow crystalline substance which explodes when rapidly raised to a red heat. When slowly heated it decomposes into mercuric bromide and mercury. It very slowly absorbs water from damp air, NH₄Br·H₂O being formed. The reverse reaction, i. e., the conversion of the hydrate into the anhydrous salt, has not yet been performed.—Chem. News, Sept. 24, 1909, 160; from Compt. rend., 148, (1909), No. 26.

**Arsenic Trioxide—Electrolytic Method of Detection in Arsenic Acid.**—Having determined that arsenic acid is absolutely non-reducible in alkaline solution and therefore incapable of yielding hydrogen arsenide on hydrolysis, E. Covelli applies this fact to the electrolytic detection of arsenic trioxide in arsenic acid, as follows: 30 Cc. of the liquid under examination, to which KOH in excess has been added, are introduced into a U-tube into the limbs of which two platinum foils are inserted and united with the poles of a Grove-element. If a slip of silver nitrate paper then is suspended in the cathode limb of the U-tube, it will be browned in the course of a few minutes if As₂O₃ is present in the liquid. In the presence of 0.01 Mgm. of As₂O₃ a metallic film is produced within ten minutes; but as little as 0.001 Mgm. produces distinct browning of the silver paper within one hour.—Pharm. Ztg., liv (1909), No. 97, 957.

**New Double Arsenates—Preparation.**—L. J. Curtman finds that if to a hot ferric chloride solution, strongly acidified with hydrochloric acid, di-ammonium arsenate solution be added to incipient precipitation, and the mixture heated, there forms a white, finely divided precipitate, of the formula NH₄H₂AsO₄·FeAsO₄. Like the corresponding phosphate, it readily hydrolyzes when washed with water. It readily dissolves in mineral acids, but is practically insoluble in 50 per cent. acetic acid. Ammonia dissolves it on heating, to a deep reddish-brown solution, from which 95 per cent. alcohol precipitates a basic double ammonium ferric arsenate. When potassium arsenate is used under the same conditions, a precipitate is obtained which appears to be the corresponding double alkali arsenate.—Journ. Amer. Chem. Soc., May, 1910, 626.
Antimony—Origin of the Name.—Schelenz says that the plausible and generally accepted derivation of the word antimony, from “antimoine,” based on the supposed unfortunate experience of mediaeval ecclesiastics, is now stated to be incorrect. The true derivation is said to be the Arabic word “Ahlmond,” introduced into Europe by Constantinus Africanus. This became Latinized to “Althimodium,” then to “Athimodium,” and finally to “Antimonium.” Pharm. Journ. and Pharmacist, March 5, 1810, 293; from La Nature, through Journ. de Pharm. et Chim. (Append), 1910, 7, 12.

Antimonium Sulphuratum—Composition and Impurities.—F. H. Alcock observes that while antimonium sulphuratum is not much used in medicine and pharmacy, it has a very large importance commercially, since it plays an important part in the rubber industry in which many tons are used annually. It is a difficult matter to get exactly what the vulcanizer requires, and for this reason it is important that more information should be available concerning this substance than is at present found in the pharmaceutical literature. The author therefore offers some practical suggestions concerning the assay of the commercial article. The substance contains sulphur in several forms, and the manufacturer wants to know what these are and their quantities. Sulphur may be present (and often is) as sulphuric acid, calcium sulphate, free sulphur (colloidal and otherwise), and as the normal trivalent sulphide and the pentavalent sulphide, and these in variable quantities. Moreover, the author has found amongst numerous other extraneous compounds calcium phosphate, and others have noticed as common admixtures sodium salts and the like. He has frequently observed a black residue when antimonium sulphuratum is treated with warm solution of alkali hydroxide, which often was found to be iron sulphide, while traces of silica in the form of sand are sometimes also revealed at this stage. Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 297–299.

Antimonium Sulphuratum and Golden Sulphides of Antimony—Rapid Method of Assay.—David Lloyd Howard and J. P. B. Harrison have devised and describe the details of a method of assay for antimonium sulphuratum which is rapid, is applicable to the sulphide preparations in general, and has the further advantage that both the antimony and sulphur can be determined in the same quantity of substance. Briefly, the sulphide is fused with sodium peroxide, thus converting the antimony into sodium metantimonate. This is brought into solution, reduced to the lower state of oxidation, and determined volumetrically by means of standard iodine solution. The sulphur thus oxidized to sulphuric acid is determined by precipitation as barium sulphate. It is stated that the antimony figure should never be less than 30 per cent., and is the only
BISMUTH SUBNITRATE.

Bismuth Subnitrate—Hydrolysis.—H. A. B. Dunning observes that while it may be generally known that bismuth subnitrate mixtures with water become acid, due to the formation of nitric acid, the reaction is usually disregarded as harmless from the therapeutic standpoint and only taken note of when dispensing the salt in aqueous mixture with carbonates. A recent complaint regarding the unpleasant acidity acquired in the course of a few weeks by a mixture of this salt, in rather large proportion, with peppermint water, prompted the author to undertake a number of experiments to determine the conditions of its hydrolyzation, and how it may be prevented or retarded. He finds that pure distilled water is more effective than peppermint water, and that hydrolysis is rapidly increased in proportion to the temperature applied to the mixture; that some forms of bismuth subnitrate are hydrolyzed more easily than others, being much more rapid in the compact form than in the "bulky" kinds; and that the hydrolysis of bismuth subnitrate may be retarded or prevented by the addition of alcohol, glycerin, volatile oils (as, for example, peppermint water and paregoric) within certain limitations as to temperature, while the presence of sodium bromide, and to a less degree sodium chloride, accelerate hydrolysis. Sterilization and aseptic condition do not retard the action. Further experiments are under way, but require some time before they can be communicated as corroborative evidence. The author, however, expresses the opinion that, from a pharmaceutic standpoint at least, the hydrated oxide or the subcarbonate would be the preferable compound for use in prescription dispensing.—Drugg. Circ., July, 1909, 331-332.

Bismuth Subnitrate—Determination of the Acid Radical in Commercial Samples.—Finding the methods of F. A. U. Smith and E. J. Brown unreliable, J. B. P. Harrison advocates the use of the nitrometer method for estimating $\text{N}_2\text{O}_5$ in bismuth subnitrate, which he applies as follows: About 2 grams of bismuth subnitrate is mixed with 20 Cc. of water and 10 Cc. of normal soda solution. The whole is brought to the boiling point with stirring, and allowed to digest for about a quarter of an hour on a water-bath, until the bismuth oxide formed has assumed a uniform lemon-yellow color, showing that the process of decomposition is complete. The supernatant liquid having been poured through a filter, the oxide of bismuth is washed with hot water two or three times by decantation, finally on the filter, and the cooled filtrate made up to 100 Cc. To 25 Cc. of the solution thus obtained is added 0.5 Cc. in excess of the quantity of normal sulphuric acid required for neutralization, using methyl orange as indicator.
REPORT ON THE PROGRESS OF PHARMACY.

This is then carefully evaporated to about 2 or 3 Cc., whereby the carbonic acid is driven off, allowed to cool, and finally decomposed in the nitrometer in the usual way. The results of the examination of seven samples of commercial bismuth subnitrate, of different makes, are exhibited in the following table:

The author reviews the various constitutional formulae for the commercial subnitrate that have been suggested by different authorities, and claims that the N₂O₅ content is practically constant, amounting to about 15.5 per cent., which is considerably lower than results hitherto published. By calculating the proportion \(x:y:z\) in the general formula \(x\text{Bi}_2\text{O}_3, y\text{N}_2\text{O}_5, z\text{H}_2\text{O}\) on the results recorded above, it is shown that the simplest constitutional formula for bismuth subnitrate of commerce is represented by \(6\text{Bi}_2\text{O}_3, 5\text{N}_2\text{O}_5, 8\frac{1}{2}\text{H}_2\text{O}\), corresponding to the composition \(\text{Bi}_2\text{O}_3\) 80.1 per cent., \(\text{N}_2\text{O}_5\) 15.5 per cent., and \(\text{H}_2\text{O}\) 4.4 per cent.—Chem. & Drugg., April 9, 1910, 46; from "The Analyst," March 1910.

VANADIUM.

Ortho-Pervanadates—Preparation and Properties.—According to P. Melikoff and E. Jelhchaninoff, the ammonium salt of pervanadic acid, \((\text{NH}_4)_3\text{VO}_6 + 2\frac{1}{2}\text{H}_2\text{O}\), can be prepared by dissolving ammonium vanadate in concentrated ammonia solution, adding hydrogen peroxide to the cooled solution, and then treating the blue liquid thus obtained with alcohol. An ammoniacal solution of this salt, when treated with a large excess of \(\text{H}_2\text{O}_2\), yields a substance which is not a single compound but contains a salt richer in oxygen. The potassium salt of pervanadic acid, \(\text{K}_3\text{VO}_6 + 2\frac{1}{2}\text{H}_2\text{O}\), can be prepared similarly, starting with the potassium salt of metavanadium or pyropervanadium acid. These results show that while the salts of orthopertantalic acid are formed in dilute solution and in presence of a slight excess of hydrogen peroxide and alkali, the analogous compounds of pervanadic acid are obtained only from concentrated solu-

SILVER.

Colloidal Silver—Instability.—H. J. Hamburger finds that while freshly made collargol preparations are always readily and completely soluble in water, forming light-brown solutions, they become partially or completely insoluble in the course of a few months. If solutions of such changed preparations are administered hypodermically, they are in his opinion liable to produce dangerous embolia. The author, therefore, advises that only fresh preparations of colloidal silver be employed therapeutically, and that even with these their solutions should be centrifuged before they are injected.—Pharm. Ztg., lv (1910), No. 19, 190; from Pharm. Weekl., 1909, 1263-1290.

Argentamine—Use as a Substitute for Silver Nitrate in Microscopy.—According to H. Kato, argentamine may be used as a substitute for silver nitrate usually employed in microscopic colorations. The reagent is prepared by dissolving 8.0-10.0 Gm. of argentamine in 30.0 Gm. of 1 per cent. potassium dichromate in microscopical solution and 100.0 Gm. of distilled water. The object to be colored, after fixation in 10-15 per cent. formol solution, is immersed in this reagent until it is of the desired brown color, then washed with water, and immersed in a solution of 1 Gm. hydroquinone in 10 Gm. formol and 100 Gm. water. The object is then dehydrated in alcohol and embedded in paraffin in the usual manner.—Pharm. Ztg., lv (1910), No. 43, 436; from Merck’s Annual Rep., April, 1910.

PLATINUM.

Platinum—Atomic Weight.—E. H. Archibald observes that the platinum salts used by earlier investigators for the determination of the atomic weight of platinum must have contained appreciable amounts of impurities, for the results obtained show considerable differences. By precipitating platinum as ammonium chloroplatinate very pure platinum metal can be obtained. It can be converted into salts of bromo- or chloroplatinic acid without using nitric acid, provided that care is taken to prevent the presence of impurities arising from the utensils employed. In order to remove absorbed water the potassium salts of chloro- and bromoplatinic acids and the corresponding ammonium salts must be heated to 400° C. and 175° C. respectively. Practically the same results are obtained whether the platinum is heated in hydrogen, and cooled and weighed at atmospheric pressure, or whether these operations are carried out in vacuo. The analyses of specimens of platinum salts from different sources, and after different purification processes, leads to the same atomic weight: if the values given by the International Commission for the other atomic weights are taken, the atomic weight of platinum cannot differ much from
Platinum Black—Method of Preparation.—F. A. McDermott recommends the following method of preparing platinum black: An aqueous solution of chloroplatinic acid, containing 0.5 Gm. of PtCl₄ in 10 Cc., is precipitated by an excess of commercial sheet aluminum. The action is very rapid, and generates a great deal of heat. Sufficient strong hydrochloric acid is then added to dissolve any excess of aluminum. When the action is over, the solution presents the uniform black appearance of a strong colloidal solution of platinum, and at the surface of the liquid a platinum mirror is often precipitated on the walls of the container. In this condition the platinum black will take a long time to settle out, but if the liquid is heated on a steam bath, the black will settle in minute flakes within a couple of hours. The supernatant liquid is usually yellow or greenish, probably from the presence of iron in the aluminum. This liquid is removed, by decantation, and the black twice heated for one hour at 100° C. with fresh quantities of strong hydrochloric acid, which will remove practically all remaining metallic impurities. It is then washed with distilled water by decantation until the wash water gives no test for chlorine with silver nitrate, washed into a small beaker with distilled water, allowed to settle, the excess of water removed by decantation or with a pipette, and the black dried in a vacuum over sulphuric acid, to avoid heating. The platinum black thus obtained is of a uniform dull black color, and between the fingers reduces to an absolutely impalpable powder. It appears to have a very considerable catalytic power. It contains 96.5 per cent. of metallic platinum. While the platinum black prepared by means of zinc becomes the gray "spongy" platinum when heated to redness, that precipitated by aluminum changes but slightly in color, although it becomes somewhat more coherent.—Pharm. Journ. and Pharmacist, April 9, 1910, 455; from Journ. Amer. Chem. Soc., xxxii, No. 3, 336.

Trivalent Platinum—Oxidation.—When finely powdered platinum tetrachloride is heated to 390° C. in pure chlorine a residue of PtCl₃ is left; but Lothar Wöhler and F. Martin find that a more convenient method of preparing it is to heat the lower chloride PtCl₂ to 390°–400 C. in chlorine for about five hours. The sesquichloride is a black or greenish powder which is intermediate between the higher and lower chlorides as regards solubility in water. With boiling water it gives an acid solution, in which the presence of H₂PtCl₆O may be assumed. The sesquichloride is almost insoluble in concentrated hydrochloric acid at the temperature of the room, but dissolves on warming, and cannot be obtained again on evaporating off the hydrochloric acid. Pt₂O₃ is obtained when platinum sesquichloride is treated with boiling soda solution or with strong caustic potash. It is a brown substance which is stable towards oxygen. It ap-
pears to be capable of existence only in the form of a solid solution in excess of PtO. In the hydrated state it occupies a middle position as regards properties between the dioxide and the lower oxide.—Chem. News, Dec. 17, 1909, 303; from Ber. d. D. Chem. Ges., 42 (1909), No. 14.

Platinum Trioxide—Preparation and Properties.—L. Woehler and F. Martin give the following method for preparing platinum trioxide: Freshly precipitated white hydrated platinum dioxide is prepared by boiling an alkaline solution of a dioxy salt and adding the solution to acetic acid. After thorough washing this is redissolved in semi-normal potassium hydroxide solution, and the yellow liquid is submitted to anodic oxidation at a low temperature. Silky leaflets of an acid potassium platinate 3PtO₃.K₂O are thus obtained, floating in the liquid. On suspending these in ice-cold semi-normal acetic acid the trioxide, PtO₃, is obtained in reddish-brown tinsel-like particles which may be purified by washing. It is a very unstable body, as evidenced by the continuous evolution of oxygen from the suspension. It is not affected by dilute acids, except by semi-normal hydrochloric acid, which dissolves it with evolution of chlorine.—Pharm. Journ. and Pharmacist, Jan. 1, 1910, 7; from Berichte, 42 (1909), 3326.

Platinum—Formation and Properties of Hexabromoplatinites.—A. Gubier and Fr. Bauriedel find that if a solution of organic ammonium bromide is added drop by drop to a solution of hydrogen platinum bromide, and the crystalline precipitate re-crystallized from hydrobromic acid, the hexabromoplatinites are obtained in the pure state. Their melting-points could not be obtained with absolute certainty, as the substances liquefy only at very high temperatures and begin to change color previously. They usually dissolve in water at the ordinary temperature, giving beautiful red liquids, and can be re-crystallized from water. They are practically insoluble in absolute alcohol unless a small quantity of hydrobromic acid or water is present, when again they form red liquids. All solutions are yellow when diluted. Concentrated caustic soda in excess colors the solution yellow; they become colorless on warming. Ammonia produces at the ordinary temperature a coloration which disappears on warming. Hydrazine hydrate decolorizes the solution at the ordinary temperature, platinum being separated and nitrogen evolved. Chem. News, Jan. 21, 1910, 36; from Ber. d. Chem. Ges., 42 (1909), No. 16.

Platinum Sulphates—Conditions of their Formation.—Marcel Delepine finds that platinum dissolves in sulphuric acid in presence of an inert gas according to the equation 2Pt + 7H₂SO₄ = 2Pt(OH) (SO₄H)₂ + 3SO₂ + 4H₂O. In contradiction to Quennessen's results the author has found that the presence of oxygen is unnecessary, and oxygen does not combine with platinum-black at the temperature of boiling sulphuric acid, though it does combine with the sulphurous gas dissolved in the acid holding the
platinum-black in suspension. The products of the reaction are platinum sesquioxsulphate, Pt(OH)(SO₃H₂), and a new red-brown crystalline substance which appears to be Pt(OH)₅SO₃H₂O. Chem. News, Mar. 4, 1910, 107; from Compt. rend., 150, (1910), No. 2.

RHODIUM.

Rhodium—Gravimetric Reduction of its Compounds.—A. Gutbier and L. v. Müller have proved that the reduction of rhodium compounds to metal by means of hydrazine hydrates can be used for gravimetric analysis. By working with solutions which are not too concentrated the metal is separated, not as a black amorphous powder, but in the form of glittering, metallic scales. The derivatives used for the analysis were "chloropenta-amminrhodium" chloride, Rh(NH₃)₅Cl₃, and the corresponding bromide, Rh(NH₃)₅Br₅.—Chem. News, Aug. 27, 1909; from Ber. d. D. Chem. Ges., 42 (1909), No. 10.

IRIDIUM.

Iridium—Atomic Weight.—E. H. Archibald has determined the atomic value of iridium, using for this purpose potassium chloroiridate prepared from two sources: one from osmo-iridium ore, the other from metallic iridium. The potassium chloroiridate was analyzed by weighing the dry salt, reducing it in hydrogen, and estimating the hydrochloric acid formed, the potassium chloride, and the metallic iridium set free. The results show a value of 192.90 for the atomic weight of iridium.—Chem. News, Sept. 24, 1909, 150.

Iridium—Halogen Compounds.—A. Gutbier and M. Riess find that concentrated hydrobromic acid when added to a solution of iridium chloride gives a dark blue solution on warming. If bromine vapor is allowed to act on the liquid the compound H₂IrBr₆ is obtained in the form of a bright blue solution. The same result can be obtained by mixing concentrated alkali bromide solution with iridium chloride solution at the temperature of the water-bath. Hexachloroiridates are formed when alkali bromide solutions act on excess of iridium chloride. These crystalline chlorosalts are converted into hexabromoiridates by dissolving them in hot dilute hydrobromic acid and allowing bromine vapor to act on the filtrate while it cools. The hexabromoiridates are anhydrous and stable in air, but are decomposed when gently heated, giving off bromine vapor. —Chem. News, Dec. 17, 1909, 304; from Ber. d. D. Chem. Ges., 42 (1909), No. 14.

Hexa-halogen Iridates—Formation and Properties.—A. Gutbier and M. Riess find when bromides of organic ammonium compounds are dropped into iridium chloride solution containing dilute hydrochloric acid, bromine escapes, and the corresponding hexachlorous iridate separates in the form of a red-brown crystalline precipitate. If the chlorous salt is boiled with
dilute hydrobromic acid, the liquid, which was originally red-brown, turns first yellow, then green, and then suddenly becomes dark blue, the chlorous salt being converted into hexabromous iridate. These bromous salts form dark blue or black crystals, which dissolve in water and in hydrobromic acid to give a blue liquid. They are not so stable as the alkali hexabromous iridates, and are much affected by light.—Chem. News, Febr. 25, 1910, 96; from Ber. d. D. Chem. Ges., 42 (1909), No. 8.

Osmium—Analytical Determination of its Oxides and Chlorides.—Otto Ruff and Ferd. Bornemann have studied the characters of the oxides and chlorides of osmium and the methods for their analytical determination. They find that ammonium hexachloro-osmate—(NH₄)₂OsCl₆—prepared from sodium hexachloro-osmate can be purified by making a cold saturated solution and salting out the double salt by means of saturated ammonium chloride solution, and potassium hexachloro-osmate can be prepared in the pure state by oxidizing the raw product, heating to 120° C., and receiving the OsO₄ in pure caustic potash, afterwards washing with alcohol. To determine osmium in presence of chlorine or fluorine in aqueous solution the following method may be adopted: Excess of alcoholic alkali is added to the solution, which is heated on the water-bath. The excess of alkali is then neutralized with \( \frac{3}{2} \) acid, and heating is continued. The osmium dioxide then separates in flakes; it is heated for six hours on the water-bath and then filtered off; the precipitate is gradually heated to 150° C. in a current of carbon dioxide containing alcohol, and then to 250° C. in a current of carbon dioxide, and then weighed as OsO₄. The authors have found that Klobbie’s method of determining OsO₄ can be adapted to the determination of the other oxides of osmium, while titration with permanganate shows the degree of oxidation of the osmium compounds. Moraht and Wischin’s osmium acid is a hydrate of osmium dioxide. The pure anhydrous dioxide is blue-black in color; it is oxidized by concentrated sulphuric acid on warming. The authors have obtained three chlorides of osmium: (1) OsCl₃, prepared by heating osmium in chlorine at a low temperature, and slowly cooling the yellowish-brown vapors thus formed. It is a hygroscopic powder, which is hydrolyzed by water. (2) OsCl₅, formed on heating osmium in chlorine to a higher temperature, and rapidly cooling the gaseous chloride. It is a brown exceedingly hygroscopic powder, which is very soluble in water. (3) OsCl₂, obtained by heating the trichloride to 500° C. in an atmosphere of chlorine at 350 Mm. pressure or in vacuo. It is a dark brown insoluble powder. —Chem. News, April 15, 1910, 180; from Ztschr. Anorg. Chem., 66 (1910), No. 4.

Osmium—Formation and Properties of Hexachloro-osmates.—Pure osmium metal was converted by A. Gutbier and K. Maish into sodium hexachloro-osmate, and by double decomposition with alkaline chlorides the
rubidium and caesium hexachloro-osmate were obtained. They form octahedral crystals of the regular system, which are soluble in cold water. The pure aqueous solutions decompose very readily in air, becoming darker, until finally a fine black powder separates. They dissolve in dilute hydrochloric acid, giving stable solutions from which they can be recrystallized. The compounds are anhydrous and are stable in dry air. They correspond in chemical behavior to the hexachloroplatinates, as well as in their crystallographic character.—Chem. News, Jan. 21, 1910, 35; from Ber. d. D. Chem. Ges., 42 (1909), No. 16.

ORGANIC CHEMISTRY.

HYDROCARBONS.

(including volatile oils and derivatives.)

Paraffin—Rapid Test for its Detection in Lard.—In view of a recent adulteration of lard with small percentages of paraffin, H. S. Shrewsbury has devised the following test: 5 Gm. of the melted lard are measured in a cylinder, transferred to a 200 Cc. Reichert flask, and saponified with 20 Cc. of glycerol soda, made by mixing 100 Cc. of approximately $\frac{8}{10}$ NaOH (453 Gm. soda and 1,000 Cc. water) with 500 Cc. of glycerol. The hot mass is dissolved in 50 Cc. of industrial (non-mineralized) methylated spirit, added very gently, drop by drop, from a pipette. The solution is allowed to cool, and its appearance observed when cold. If it is clear, paraffin wax is absent. As little as 2 per cent. of paraffin wax makes the solution cloudy with opaque flocculi. After some time the solution sets to a jelly, when it may again be observed. Genuine lard gives a slightly opalescent but homogeneous jelly. Two per cent. of paraffin wax shows as opaque flocculi distributed throughout the otherwise nearly transparent jelly, and gives a very characteristic cloudy appearance.—Pharm. Journ. and Pharmacist, Sept. 18, 1909, 365; from Analyst, August, 1909, 348.

The above test devised by Mr. Shrewsbury is according to the opinion of Dunlap not so delicate as that of Holde for the detection of mineral oil in fatty oils, which can advantageously be applied to the testing of lard for paraffin wax. The test is applied thus: From 0.3 to 0.45 Gm. (10 drops) of the melted fat is saponified in a test-tube with 5 Cc. of approximately $\frac{8}{2}$ alcoholic potash, and to the clear hot soap solution water is added in successive quantities of about 1 Cc., the solution being carefully observed after each addition of water. While pure lard gives a clear solution of soap after dilution with 5 Cc. of water, the presence of even 0.5
per cent. of paraffin wax is indicated by the formation of a turbidity, the "silky" appearance of which is characteristic of paraffin wax. It is possible by this method to detect as little as 0.3 per cent. of paraffin wax in lard or margarine fat. The method also serves as a rapid sorting-test in the examination of tallow, which is now frequently adulterated with "fish-oil stearine" and paraffin wax, samples recently examined containing from 1 to over 20 per cent. of the latter adulterant.—Ibid., Jan. 8, 1910, 27; from Analyst, Dec., 1909, 524.

Bismuth Betanaphtholate has been examined by W. A. Puckner and W. S. Hilpert with the idea in view of comparing the various brands on the market and to establish a uniform standard. The paper appears in "Proceedings," 1909, 859–868.

Naphthol-Halogen Derivatives Used as Disinfectants.—Bechold mentions a number of halogen derivatives and their respective uses and values as disinfectants. Bromo- and Chloro-3-Naphthol are most powerful disinfectants, exceeding mercurial compounds in bactericidal power. Tribromobetanaphthol is the most active of these against staphylococci, streptococci, and diphtheria bacillus; dibromobetanaphthol is most effective against B. coli. Dibromonaphthol and dichloronaphthol are active against B. typhosus, and the activity decreases as the chlorine or bromine in the molecule is lessened. All these are practically odorless and non-toxic. Tetrabromoparadiphenol and tribromodicresol are very active against staphylococci, but are less active than lysol against B. coli. Tribromo- and tetrabromobetanaphthol, tetrabromo-orthocresol, and tetrabromo-orthodiphenol, although active in some directions, are without action towards the tubercle bacillus. Tri- and tetrabromonaphthol and tetrachloro-orthodiphenol are very active disinfectants of pus. A 1 per cent. solution of tri- or tetrabromonaphthol will sterilize the hands perfectly in eight minutes. In addition to the above, fifteen other naphthol-sulphonic and bromo-derivatives were experimented with. These were found to be inert towards staphylococci.—Pharm. Journ. and Pharmacist, Febr. 26, 1910, 237; D. Med. Wschr., 1909 (45).

Benzaldehyde Ammonia—Formation and Properties.—Francis finds that when ammonia acts at a low temperature on a concentrated solution of benzaldehyde in a mixture of alcohol and water, a crystalline adduction product of composition \(C_{8}H_{5}(CHO)_{2}NH_{3}\) separates. This "benzaldehyde ammonia" is ad-dioxy-dibenzylamine, and is very unstable, rapidly giving hydrobenzamide, water, and benzaldehyde. Further, the author finds that "p-tolylaldehyde" behaves similarly, giving the corresponding compound with ammonia.—Chem. News, Aug. 27, 1909, 107; from Ber. d. D. Chem. Ges., 42 (1909), No. 10.

Azobenzene and o-Oxy-Azobenzene—Production from Aniline by the Action of Caustic Potash.—A. Bacovescu finds that when colorless freshly
distilled aniline is intimately mixed with caustic potash the mixture becomes slightly warm and turns reddish brown. The reaction is at its maximum when one part of aniline is present to twelve parts of alkali. The products of the reaction are "azobenzene" and "o-oxy-azobenzene, \( \text{HO.C}_6\text{H}_4\text{N} : \text{N.C}_6\text{H}_5 \). Caustic potash also acts on azobenzene and converts hydrazobenzene into azobenzene. Azobenzene is also produced when \( \text{KMnO}_4 \) acts on aniline, or when aniline is oxidized in alkaline solution by hypochlorite. It is probable that oxidation by the oxygen of the air takes place in the experiments described, and that the caustic potash merely induces the reaction.—Chem. News, Oct. 29, 1909, 219; from Ber. d. D. Chem. Ges. 42 (1909) No. 13.

Italian Ichthyol—Yield and Characters.—F. Marino-Luco and Jole Tonolli have subjected a bituminous slate occurring in large quantities in Tuscany to dry distillation in iron retorts, obtaining about 8 per cent. of a dark brown oil, which on fractionation yielded a fraction boiling between 100° C. and 255° C. The dried oil was composed of 69.56 per cent. C., 8.73 per cent H., 2.27 per cent. N., 7.79 per cent. S., and 11.65 per cent. O. The ichthyolsulphonic acid prepared from this oil by Rudolph Schröter's method is a dark brown, soft, viscous mass, soluble in water, but insoluble in salt solutions and completely precipitable from its aqueous solution by saturated solution of sodium chloride. 10 Gm. of the oil yielded with pure concentrated sulphuric acid 12 Gm. of ichthyolsulphonic acid, from which an ammonium salt was prepared corresponding in all its characters with the well known German preparation. It contained 1.24 per cent. ammonia, 13.05 per cent. total sulphur, of which 2.52 per cent. was in sulphonic—the other 10.53 per cent. in sulphidic combination—thus establishing a relation of the sulphonic to the sulphidic sulphur of 1:417, an important consideration since the value of ichthyol depends upon its content of sulphidic sulphur, which is comparatively high in this Italian product.—Pharm. Ztg., LV (1910), No. 37, 376; from Gaz. Chim. 39, II, 575-579.

Amber—Solubility in Different Solvents.—Experimenting with amber in small, hard, amber-colored pieces, interspersed with a few softer, white pieces, Coffignier subjected the substance to the action of various solvents at their boiling point for two hours with the following results, showing the percentage of substance remaining undissolved: Alcholoh 85.7; methylalcohol, 88.7; amylalcohol, 75.8; ether, 81.2; chloroform, 82.7; benzol, 78.8; acetone, 76.70; oil of turpentine, 83.1; benzaldehyde, 67.9; aniline, 69.3; amyl acetate, 70.0; carbon tetrachloride, 88.5.—Pharm. Ztg., lv (1910), No. 20, 205; from Chem. Zentralbl., 1910, No. 6.

Nerol—An Abundant Constituent of Oil of Helichrysum Angustifolium.—Heine states the essential oil of Helichrysum angustifolium is very rich in "nerol," yielding as much as 40.65 per cent. of neryl acetate; and
since nerol is a valuable constituent of "synthetic rose oil," the oil of helichrysum should prove a valuable commercial source of this. Nerol has a rose-like odor, and has been found, in small quantities only, in the oils of neroli, petit-grain, rose and lignaloe. To obtain pure nerol, the saponified oil is treated with phthalic anhydride or the anhydride of a dibasic acid, with which it forms acid esters. These are either separated by saponification and shaking out with immiscible solvents, or by fractionation in vacuo; or the nerol is converted into the benzoic ester, and separated from the more volatile bodies which accompany it by fractional distillation under reduced pressure.—Pharm. Journ. and Pharmacist, July 24, 1909, 105: from Chem. Techn. Report, 33 (1909), 295.

Terpinolene—A New Adulterant of Volatile Oils.—John C. Umney mentions as the latest adulterant of volatile oils a by-product resulting from the manufacture of terpineol, which has received the name of "terpinolene." It is apparently formed by the action of mineral acids in the process of preparing terpineol from oil of turpentine, constituting an optically inactive hydrocarbon, which lends itself admirably for the adulteration of spike lavender oil, for which purpose it is said to be used.—Chem. & Drugg., Aug. 14, 1909, 292.

In connection with the preceding it is interesting to note some observations made by Ernest J. Parry in an article on adulterated petitgrain oil (which see), which evidently refer to the adulterant mentioned by Mr. Umney. Mr. Parry says that manufacturers of terpineol appear to accumulate a large amount of residues which contain the oxidation and other alteration products of turpentine formed during the course of terpineol manufacture. This oil can be obtained for a few pence per lb., and is a viscous oil, containing a fair amount of free alcoholic substances, of high specific gravity (up to 0.930) and various hydrocarbons. It has not yet been thoroughly investigated, but it appears to be imported into England, and he believes that it is used for the adulteration of some essential oils. Indeed, that such products are offered is plainly evident from a circular recently issued by a Continental firm of chemical manufacturers in which the following statement occurs:

"We beg to draw your attention to our synthetic 'neutral ethers,' which is a product suited for mixing with essential oils which naturally have a high ester-content; 1 per cent. of our ethers appears on saponification as 3 per cent. of esters, such as linalyl acetate, and it is absolutely impossible for an analyst to differentiate between such esters and our product." This "neutral ether" proved to be impure ethyl citrate to which attention has been previously called.—Ibid., Sept. 4, 1909, 410-411.

Volatile Oils of the U. S. P., VIII—A Critical Review.—At the January meeting of the New York Branch of the A. Ph. A., Paul Jeancard and Conrad Satie communicated a comprehensive criticism and review of volatile
oils described in the U. S. P., VIII, in which they point out that these descriptions are not always consistent with the established facts of science and industry. The authors say that in most European countries the function of pharmacopoeias is to consider products only as utilized in pharmacy. In the United States, on the other hand, the Pharmacopoeia has the authority of a legal standard not only for products which are intended for pharmaceutical use, but for table consumption as well, and that therefore an official book with so broad a province should maintain great exactitude in its descriptions and strict precision in the analytical methods which are used to demonstrate the quality of products. But, notwithstanding the great amount of work which has been accomplished by the authors of the U. S. P., VIII, it is lacking in this precision. The high professional standing of Messrs. Jeancard and Satie as authorities on volatile oils and perfumes makes their criticism on the description of these in the U. S. P., VIII, easily one of the most important contributions for the guidance of the committee having in charge the revision of the U. S. P. IX. The authors consider the subject in two divisions—collecting in the first in a systematic manner the analytical methods scattered here and there in the Pharmacopoeia, and in the second part looking up and discussing the individual oils and some of their constituents. These must necessarily be referred to in the original, but the following questions will indicate the drift of the arguments made for the betterment of the pharmacopoeial descriptions: "Volatile oils are mixtures of certain chemical bodies, such as terpenes, alcohols, ketones, etc. They have no fixed physical or chemical properties, the properties varying within certain limits, which depend on the place of origin of the plant, the climatic influences, the condition of cultivation, method of preparation, etc." "The limits of variation in a given property of a substance, which have been recorded by investigators during a number of years, may be spoken of as 'general limits.' These represent the extremes of variation; but the authors also recognize 'annual limits,' which, however, would be more restricted than the former and would necessitate a more exact determination of the purity of a substance. A pharmacopoeia which is in force for ten years or longer should make use of general limits only, since it is evident that those limits represent the extremes of variability. But a pharmacopoeia whose directions have authority for ten years is a strange thing in an epoch in which the most important discoveries succeed each other, and when industrial developments are revolutionizing the customs of the world." "The United States Pharmacopoeia possesses all the faults of the pharmacopoeias of other nations. These faults are results of the method of compiling the books. They are edited with much care and with inexhaustible patience, and are so thoroughly edited that by the time they appear they are about ten years behind contemporary science."—Amer. Drugg., Jan. 24, 1910, 40-43.
The Volatile Oils of the U. S. P. is the subject of a paper presented at the meeting of the New Jersey Pharmaceutical Association by Charles H. LaWall, in which he makes some practical observations upon facts in connection with volatile oils in general and the official oils in particular. He states that there is no class of official substances about which the retail pharmacist is more at the mercy of the manufacturer than that of volatile oils, and therefore points out the character of tests and examination prescribed by the Pharmacopoeia which can conveniently be carried out by the pharmacist of average ability. In recapitulating, he mentions that of the thirty-four volatile oils officially recognized in the U. S. P. VIII, there are ten only which require apparatus or manipulative skill not usually possessed by the pharmacist; but that, after all, the criticism by which the pharmacist should finally judge a volatile oil, even when it answers the official requirements, is that afforded by the physical attributes of odor and flavor. For, no matter if an oil responds to every given test, if it be not of fine quality in this respect, it is wise to reject it upon this ground, even if it be cheap.—Proc. N. J. Pharm. Assoc., 1909, 102-104.

Essential Oils—Value of Refraction Indices.—Ernest J. Parry says that the experience of the past few years has demonstrated the fact that the refractometer is an absolutely necessary instrument in a laboratory where essential oils are examined. It is true that there are cases where the direct determination of the refractive index of an oil gives little information, but this is equally true of the optical rotation and the specific gravity. But as in many cases the common adulterant of a given oil has a refractive index well outside the limits of that of the pure oil, this determination often becomes of great value. The fullest information, however, can be obtained by using one's judgment in the examination of the various fractions obtained in the fractional distillation of an oil where, with type samples, fairly constant results are obtained and compared with those of the suspected oil. For example, an oil with an apparently normal ester-content, such as lavender oil, will show a maximum amount of esters in a given fraction, whereas if adulterated with such esters as ethyl citrate, the esters will be found in quite a different fraction, and will affect the refractive index of that fraction in a quite abnormal manner. Again, the very low refractive index of alcohol will be at once an indication of the presence of small quantities of that body—a point of great importance when one is dealing with oils of which only small samples are available, such as otto of rose. Where alcohol has been added to adjust the high refractive index of another adulterant, it is at once indicated by a distinct rise in the refractive index of the oil after being well washed with water. Mr. Parry appends a long list of refractive indices of: (1) Constituents of essential oils; (2) of essential oils themselves; and (3) of essential-oil adulterants and other bodies. These indices in most cases represent a number of deter-
minations in each case, many of them over five different samples of the same body and in some as high as 20 to 30 samples.—Chem. & Drugg., Jan. 29, 1910, 178.

Discussing the same subject, T. F. Harvey and J. M. Wilkie say that the observation of the refractive index of a fluid substance is so conveniently and rapidly made with modern instruments, and requires so small an amount of material, that it is worth observing even in those cases where (as with many essential oils) the information obtained is not of much diagnostic value. It still serves in these cases to mark, for example, sudden changes in the character of supplies and to make rapid comparisons between bulk consignment and buying samples, etc. For technical purposes the Abbé refractometer (scale 1.3000 to 1.7000, with water-jacketed prisms connected with a heating-apparatus, is commonly used. In this instrument about two drops of the liquid is enclosed as a thin film between the faces of two prisms made of suitable glass, light (which may be artificial) being reflected from a mirror through the prisms. The refractive index is recorded upon a scale reading directly to the third decimal, the fourth place being obtained by eye-estimation. A number of consecutive readings should yield figures not differing by more than about 0.0002. The adjustment may be checked occasionally with pure distilled water, which has an index of 2.3330 at 20° C. A heating-apparatus is provided in order to bring the circulating water, and consequently the prisms, to a constant temperature, which may be arbitrarily chosen, and which for solid fats, such as butter, etc., is usually 40° C., and for liquid substances 20° C. These authors also append to their paper a long tabulated list giving the refractive indices—often in very many samples of the same substance—of: (1) volatile oils, B. P., 1898; (2) volatile oils, not official; (3) fixed oils; (4) corrections for the refractive indices determined in the preceding lists.—Ibid., March 19, 1910, 50-51.

Volatile Oils—Use of the Centrifuge in the Assay.—Frank X. Moerk, following up his suggestion made in a paper presented to the Association in 1908 (see Proceedings, 1908, 900) that the assays of some of the volatile oils could be more conveniently and accurately made by the aid of the centrifuge than by the official method of shaking the oils with reagents in a flask or burette, has made and records a number of experiments with different oils which substantiate his opinion. Using the Babcock cream bottles and calculating the undissolved oil to volume percentage, the experiment as carried out upon the oils of cloves, pimenta and thyme, is described as follows: "Mix the carefully measured oil with 30–35 Cc. alkali solution, cork the bottle, shake thoroughly for several minutes, add sufficient alkali solution to bring the mixture well up into the graduated part, cork and whirl in the centrifuge until the insoluble oil separates as a clear layer." This, with 800–1000 revolutions per minute, requires 3 to 10 minutes. It is important that the bottle be corked during centrifugation.
Remarkably constant results are thus obtained as shown in a tabulated statement. In the case of oil of cassia, in which the aldehyde is dissolved in bisulphite, certain modifications of the official method are necessary before subjecting the mixture to the action of the centrifuge.—Amer. Journ. Pharm., July, 1909, 326–328.

**Volatile Oils—Antiseptic Value in Dentistry.**—D. Gilmour, among other properties which make volatile oils valuable in dentistry, mentions the following in the order of their antiseptic value, together with their principal uses: *Oil of cassia*, undoubtedly the most potent as a germicide, has an antiseptic value equivalent to 1 drop in a culture of 2233 drops. In the same way *oil of cinnamon = 1–2100; oil of cloves, 1–1150; oil of bay, 1–1028; oil of peppermint, 1–875; oil of eucalyptus, 1–600; oil of thyme, (?) ; oil of cajuput, 1–120; oil of gaultheria*, not sufficiently antiseptic to be of any particular use as a root-canal dressing.—Pharm. Journ. and Pharmacist, May 21, 1910, 844: from Brit. Dental Journal.

**Volatile (and Fixed) Oils—Use of Antiseptic to Determine the Iodine Number.**—F. Borde, following the Hibl method for determining the iodine number of volatile and fixed oils, titrates the excess of iodine with a solution of 1.88 Gm. antipyrine in 100 Cc. of 50 per cent. alcohol, instead of sodium thiosulphate solution. The end of the titration is easily recognized by a faint yellow color. 1 Cc. of the antipyrine solution (which keeps indefinitely) corresponds to 0.254 iodine.—Pharm. Ztg., lv (1910), No. 18, 181; from Bull. des. Scienc. Pharmacol., 1909, 654.

**Ajowan Oil—Constituents.**—Schimmel & Co., after the lapse of a considerable time since they carried out any investigations as to the separate constituents of oil of ajowan seed (*Carum Ajowan, Benth. et Hook, Fytchoitis Ajowan, D. C.*), have resumed their investigations of a mixture of hydrocarbons from this oil, usually designated as "Thymene," of which a large quantity had been reserved for this purpose. Previous researches had shown that "thymene" is a mixture of p-cymene and an unknown terpene. In order to determine the nature of the terpene it was split up into five fractions, of which the first, third and fifth in particular were more closely investigated, as explained in some detail. The results show that "thymene" is mainly composed of p-cymene, and that of terpenes, a-pinene, dipentene, and y-terpinene were present—the last-named in the largest proportion. Phellandrene (α and β) although a constituent of oil of ajowan *herb*; could not be detected.—Schimmel’s Semi-An. Rep., Oct. 1909, 14.

**Oil of Star Anise—New Constituents.**—Besides anethol, of which star anise oil contains about 90 per cent., the bodies so far definitely ascertained to be constituents of the oil are: pinene, l-phellandrene, hydroquinone ethyl ether, methyl chavicol, anise aldehyde, anisic acid, and anisic ketone. To these safrol was added by Oswald (1891), while Tardy (1902)
states that it contains terpineol, a laevorotatory sesquiterpene, and a body melting at 213° C. Absolute proof of the presence of the two last-named bodies has, however, not been given, and Schimmel & Co. have therefore considered it desirable to repeat the investigations as regards the terpenes, especially in view of the knowledge which has been gained in the chemistry of terpenes in recent years. The results of these investigations, which are described in some detail, show that star anise oil contains, in addition to its previously known constituents, \( \text{p-cymene, cineol, safrol, and terpineol} \); also, that the \text{phellandrene} present is a mixture of \( \text{l-a-and-\beta-phellandrene} \).

\textbf{Arnica Root Oil—Constituents.}—Kondakow has isolated from the volatile oil of arnica root an unsaturated hydrocarbon, m. p. 176° to 180° C., a solid body, m. p. 69° C., and a sulphurous compound. He was also able to confirm the presence of iso-butyl phlorol and of dimethyl-thymohydroquinone, which were originally discovered by Siegel.—Schimmel’s Semi-An. Rep., Oct., 1909, 25: from Journ. f. prakt. Chem., ii, 79 (1909), 505.

\textbf{Artemisia Oil—High Percentage of l-Camphor a Constituent.}—Th. Whittelsey has obtained from the green branches and leaves of a kind of \textit{Artemisia} (perhaps \textit{A. Cana}, Pursh.) having its habitat at the Western parts of North America, 1.2 per cent. of a powerfully aromatic volatile oil, which on fractionation yielded 44.5 per cent. of l-camphor. This camphor was identified by preparing its semi-carbazone. It is possible to obtain the camphor directly from the original oil by placing it in a freezing mixture. The oil showed the following constants:—Sp. gr. at 15° C., 0.9405; opt. rot. 19.09° C.; refract. index \( \text{(20° C.,)} \) 1.4702; acid no., 4.1 to 4.2; sap. no., 22.7 to 23.9; sap. no. after acetylation, 110.3 to 111.8. The occurrence of l-camphor in essential oil had up to the present been observed only in the oils of feverfew, tansy, \textit{Artemisia Herba-alba}, \textit{Blumea balsamifera}, and of a species of \textit{Salvia}, possibly \textit{S. grandiflora}.—Schimmel’s Semi-An. Rep., April, 1910, 19; from Wallach Jubilee Publication (1909), 668.

\textbf{Oil of Artemisia Herba-alba var. densiflora—Characters and Constants.}—Schimmel & Co. having again distilled a parcel of the herb of \textit{Artemisia Herba-alba}, obtained a yield of 0.58 per cent. of oil, which differs in several respects from that described by them in a previous report. It is also of a brownish-yellow color and is distinguished by a pungent odor, which was only perceptible in a slight degree in the former sample. On the other hand, in the recently-distilled sample the odor of thujone or sage does not appear until some time after preparation. But the principal difference lies in the change of optical rotation, for whereas the old oil was laevorotatory, the new sample is dextro-rotatory; it also contains considerably more alcoholic constituents than did the old oil. All these
variations may perhaps be explained by the fact that the oil distilled last year was prepared from the flowering herb, whereas on the present occasion the flowers were very little developed. The constants of the new sample are as follows: \( d_{150} 0.8994, a_D + 14^\circ 5', n_{D20\circ} 1.46684, \) acid no. 4.6, ester no. 350, ester no. after acetylation 163.3; dissolves in 1.8 vol. and more of 70 per cent. alcohol, with separation of paraffin.—Schimmel's Semi-An. Rep., Octob., 1909, 25.

Asparagus Oil—Yield and Characters.—Haensel's Report describes the volatile oil obtained by distillation from dried asparagus roots, previously carefully purified and washed. The yield calculated on the original drug used was 0.0108 per cent. of a dark brown oil, having an intensely acridulous and very strong odor and giving the following constants: Sp. gr. at 23° C., 0.8777; saponification no. 101; acid no. 33; ester no. 68. A solid acid, identified to be palmitic acid, was isolated from this oil.—Pharm. Ztg., liv (1909), No. 83, 822.

Algerian Aurantiaceous Volatile Oils—Properties.—A. Chapus describes a number of Algerian volatile oils obtained from the orange. He finds that Algerian Bigarade neroli oil is richer in esters than that produced in the South of France; but its optical rotation and specific gravity are normal. It contains from 25 to 31.99 per cent. of esters calculated as linalyl acetate; its \( a_D = + 5^\circ 42' \) to \(+ 6^\circ 6'\); and its specific gravity ranges from 0.8723 to 0.8768. Algerian Portugal neroli oil is richer in esters, and has a higher specific gravity than Spanish oil, but the optical rotation of the latter is higher. The figures obtained with Algerian oil are: Specific gravity 0.8731; \( a_D = + 26^\circ 15' \); esters 34.18 per cent. Algerian Bigarade petitgrain oil is markedly laevorotatory, \( a_D = -5^\circ 5' \); specific gravity 0.8755; esters 42.39 per cent. Algerian Portugal petitgrain is dextrorotatory, \( a_D + 21^\circ 33' \); specific gravity 0.8705; esters 21.62 per cent. These figures are based on experiments with oils distilled from material gathered in the presence of the author from native Algerian varieties of the respective orange trees. The observed differences are attributed mainly to climatic influence, modified possibly by the botanical variety of the source of the material. The influence of the method of treatment is also under consideration.—Pharm. Journ. and Pharmacist, Jan. 22, 1909, 81; from Journ. de Pharm. et Chim., 30 (1909), 484.

Bigaradia Oil (Oil from the Rinds of Bitter Oranges)—Constants.—Roure-Bertrand Fils have determined the constants of Bigaradia oil (from the rinds of bitter oranges) produced in the Comoro Islands to be as follows: Sp. gr. 15° C., 0.8812; opt. rotation, + 42° 13'; soluble in all proportions of 90 per cent. alcohol; insoluble in 80 per cent. alcohol.—Rep. Roure-Bertrand Fils, October, 1909, 42.

Oil of Basil from Comoros—Constants.—Roure-Bertrand Fils have determined the constants in oil of Basil received from the Comoro Islands, of
which they report as follows: Sp. gr. at 15° C., 0.9588; rotation, + 0° 35': soluble in 0.3 vols. of 80 per cent. alcohol; sapon. no. 1, 4.2; esters (calculated as linalyl acetate), 1.5 per cent. The oil possessed a fine odor. Report of Roure-Bertrand Fils, October, 1909, 42.

Bay Oil—Low Eugenol Content from the Fiji Islands.—Schimmel & Co. report that two samples of bay oil produced in the Fiji Islands, sent to them from the Imperial Institute in London, showed respectively a phenol content of 23 and 24 per cent. As compared with the normal commercial oils, which contain about 60 per cent. of eugenol, the two samples show an exceptionally low phenol-content, which may be due to the manner of manufacture. In the course of the distilling-process one part of the bay oil separates out on the surface of the receiver, while the other sinks to the bottom; hence if a normal oil is to be produced, these two parts must be carefully mixed after distillation. If this is neglected, the result is that the oils obtained are sometimes too light, and at other times too heavy, because owing to unworkmanlike distilling, they lack some portion of either the light or the heavy oil. It may therefore be surmised that in the case under review a similar mistake was made during the distillation. Schimmel's Semi-An. Rep., October, 1909, 27.

Oil of Bergamot—Encouraging Development of its Production following the Earthquake.—Discussing the consequences of the earthquake on the Sicilian and Calabrian essential-oil industry, Eduardo Jacob, of Catania, who is regarded an authority, makes some encouraging observations concerning the progress made in restoring this industry. "In the case of oil of lemon, only the principle center of collection, Messina, was destroyed, while the extensive producing area remained almost free from damage by earthquake; on the other hand, in the case of bergamot oil, the entire producing country was ravaged by shocks, and it will therefore be desirable to add a word concerning the present conditions in Southern Calabria:—The manufacture of oil of bergamot invariably takes place on small farms which are scattered round about the numerous towns, townships and villages of Southern Calabria. All these places have been more or less destroyed by the earthquake, and a large part of the population is buried under the ruins. But as everywhere the communities were small (even in Reggio the number of survivors probably does not exceed 20,000), it was much easier here than it was in Messina to procure new dwellings for the remaining people, and to-day the visitor to Calabria sees everywhere in the earthquake-region round about the older townships new and more or less pleasantly built settlements of sheds. In Messina scarcely one-third to one-half the survivors have returned to the quarter of the town where the sheds have been erected, and these are mostly of the poorer classes; but in Calabria it may be said that the whole surviving population has returned, especially the well-to-do. For this reason life in that district was able to
resume its normal course much more quickly than was the case in Messina. The soil is again being cultivated; the lemon, bergamot and orange gardens being tended, and the simple tools required for the bergamot industry have been partly dug up from the ruins and partly replaced by new ones; in short it may be asserted that, in common with other occupations, the bergamot oil industry has here again overcome its initial difficulties and is now able to go on as before. Schimmel's Semi-An. Rep., October, 1909, 57-59.

Oil of Bergamot—Ingenious Adulteration.—John C. Umney has examined several samples of oil of bergamot which, although the esters appeared to be normal in quantity, aroused his suspicion by a difference in odor and a curious weakness. Further experiments lead to the belief that these particular samples were adulterated with oil of orange or its terpenes, which at present prices is much cheaper than oil of bergamot. By the use of this terpene, however, the ester percentage is reduced and the optical rotation minimized; but to counterbalance these divergences, a splendid body was forthcoming in "terpineol acetate," which has a pleasant but weak odor and the following characters:

Specific gravity at 150° C. ...................... about 0.960.
   Optical rotation (100 mm.) ...................... nil.
   Boiling range ................................. 220° to 230° C.

Commercial samples estimated approximately 90 per cent. of terpineol acetate. This is now being supplied by manufacturers abroad, with instructions for mixing and a statement that an addition of 1 per cent. to the particular oil will raise the indicated ester percentage of the oil, calculated as linalyl acetate, by a certain proportionate amount.

Among the bodies that are being offered in addition to linalyl acetate are ethyl citrate, ethyl benzoate, and benzyl benzoate, the use of which in raising the apparent ester percentage is obvious from the following data:

1 per cent. of ethyl citrate = apparently 2.1 per cent. of linalyl acetate.

1 per cent. of ethyl benzoate = apparently 1.1 per cent. of linalyl acetate.

1 per cent. of benzyl benzoate = apparently 1.0 per cent. of linalyl acetate.

In the samples of bergamot oils above referred to, the presence of terpineol acetate was determined without difficulty by saponification of the oils, the lilac odor of terpineol being then sufficiently marked to be observed, even through the powerful odor of linalool.

The author concludes that any bergamot oil having a rotation over + 20° C. should be rejected, and over + 18° C. should be viewed with grave suspicion. Two samples of the present season's bergamot oil, of undoubted purity, gave the following constants:
REPORT ON THE PROGRESS OF PHARMACY.

Solubility 34°, refractive specific rotation, 298 leuca.

Furthermore, any oil yielding a non-volatile residue of under 5 per cent. after drying for two hours on a water-bath should be deemed impure and sophisticated with bodies yielding practically no residue.—Chem. & Drugg., Sept. 4, 1909, 411.

Birch-bud Oil—Characters.—Schimmel & Co. find that birch-bud oil distilled during the present season has more or less the same constants as a sample described in a previous report. The odor was pleasantly balsamic, the color lemon-yellow, and the sample contained a large proportion of paraffin, crystals separating out plentifully at + 8° C., while at + 5° C. it was completely congealed. Its other properties are as follows: d<sub>15°</sub> 0.9730, a<sub>D</sub> — 5° C. 34°, n<sub>D</sub> 20° 1.50153, acid no. 2.8; ester no. 51.4 = 24.1 per cent. acetate of a sesquiterpene alcohol of the formula C<sub>15</sub>H<sub>20</sub>O. Ester no. after acetylation 150.0 corresponding to 66.4 per cent. total alcohol C<sub>15</sub>H<sub>20</sub>O. 0.25 vol. of 90 per cent. alcohol was sufficient to dissolve the oil, but when more alcohol was added a plentiful separation of paraffin set in quickly.—Schimmel’s Semi-An. Rep., Octob., 1909, 28.

Cajuput Oils.—Characters as Obtained from Different Species of Melaleuca.—Baker and Smith have examined the cajuput oils obtained from Melaleuca uncinata and from M. nodosa. The oil from M. uncinata had the following characters; Specific gravity, 0.9259; rotation, + 7.2°; refractive index, 1.4788; saponification number, 3.05; solubility in 70 per cent. alcohol, 1 in 1.5. The oil contains much cineol, a small amount of d-pinenone, a sesquiterpene, and a crystalline substance melting at 72.5° C., to which the authors give the name uncineol. It is an alcohol having the formula C<sub>10</sub>H<sub>18</sub>O. The oil from Melaleuca nodosa contained 33 per cent. cineol, the remainder being principally d-pinenone, with a little sesquiterpene: specific gravity, 0.898; rotation, + 11.6°; refractive index, 1.4689; saponification number, 7.24.—Chem. and Drugg., Jan. 29, 1910, 151.

Oil of Camphor—Presence of Cadinene in High-boiling Fractions.—Twenty years ago (1889) Schimmel & Co. reported the presence of cadinene in the high-boiling fractions of camphor oil. Observations of the low sp. gr. of some camphor oil fractions of high boiling points have now induced them to investigate the subject afresh. For this purpose they employed a pale yellow, heavy camphor oil fraction possessing the following constants: b. p. 106° to 120° C. (7 Mm.) d<sub>15°</sub> 0.9378, a<sub>D</sub> + 11°, n<sub>125°</sub> 1.50188. Any phenols present were removed by shaking with 5 per cent. caustic soda liquor, and the remainder was fractionated. The b. p. now lay between 97° and 116° C. (5.5 to 6 Mm.). As the b. p. rose the

the sp. gr. decreased from $d_{150} = 0.942$ to $d_{150} = 0.905$, while on the other hand the rotation increased from $a_D + 4^\circ 52'$ to $a_D + 16^\circ 53'$. No hydrate, nitrosoite or nitrosate was obtained, but from the intermediate fractions they succeeded in isolating small quantities of a nitrosochloride, although the yield of this was too small to admit of further examination. Cadinene must therefore presumably be looked for in fractions of oil having still higher boiling points.—Schimmel’s Semi-An. Rep., Oct., 1909, 31.

**Camphor—Rapidity of Volatilization.**—Charles H. LaWall has made a series of experiments undertaken with the object of determining to what extent, if at all, manufacturers of camphorated oil and spirit of camphor, when products are found to be below strength, are justified in attributing this deficiency to the volatilization of the camphor in the preparation. The results of these experiments, which are given in some detail, show that both lump camphor and the powder steadily lose by vaporization, but that the preparations mentioned do not lose any appreciable amount of camphor by volatilization—the spirit even increasing appreciably in strength.—Proc. N. J. Phar. Assoc., 1909, 545-546.

**Synthetic Camphor—Comparison with Natural Camphor.**—W. Johnson makes a plea for the recognition of synthetic camphor in the next British Pharmacopoeia, on the ground that the two camphors, natural and synthetic, are identical in molecular composition, smell, appearance, solubility and rubefacient properties, and probably also in therapeutic action. Some of the earlier samples of synthetic camphor did not have the same smell or solubility, but that has now been rectified in the best makes. The points of dissimilarity of the two camphors are the following: The synthetic is slightly purer than the refined natural camphor, since it is free from oil of camphor. The synthetic is optically inactive and is said by some to melt at $165^\circ$ C.; the natural is dextrorotatory and melts at $175^\circ$ C., but it is reported that the new synthetic camphor also shows a melting point of $175^\circ$ C. The new synthetic camphor appears to be slightly less active on the respiratory and nervous systems, but the difference is so small as to be negligible. In fact, the author quotes the opinions of qualified scientists and therapeautists which justify his belief that the two camphors are equal in quality and effect.—Pharm. Journ. and Pharmacist, Oct. 30, 1909, 534.

**Oil of Cardamom—Monograph Proposed for the National Formulary.**—In the course of a discussion following the submission of formulas by George M. Beringer for some new basic elixirs proposed for introduction in the revised edition of the National Formulary, some doubt was expressed as to the availability of authentic and pure oil of cardamom required in the formula for a compound elixir of cardamom, as an article of commerce and likewise as to its keeping. Mr. Beringer has therefore undertaken and completed a very thorough inquiry into the subject, cor-
responding with a number of representative firms, manufacturers, and persons of authority, which are communicated in an abstract together with a personal experience with this oil extending over a number of years during which he has satisfactorily employed it as a flavoring ingredient of various preparations. On the basis of reliable information so obtained, which should be consulted in the original paper, Mr. Beringer proposes the following “Monograph” for inclusion in the N. F. if this oil should be admitted in that standard:

Oleum Cardamomi—Oil of Cardamom.

A volatile oil distilled from the seeds Elettoria cardamomum White et Matron (Fam. Zingiberaceae). It should be kept in well-stoppered amber-colored bottles, in a cool place, protected from light.

A colorless or very pale yellow liquid having the characteristic aromatic, penetrating, and somewhat camphoraceous odor of cardamom and a warm, persistently pungent, and strongly aromatic taste.

Specific gravity 0.924 to 0.947.

Very soluble in alcohol and dissolves readily and clearly in 4 volumes of 70 per cent. alcohol.

It is dextrogyrate, the angle of rotation varying from +22° C. to +40° C., in a 100-Mm. tube, at a temperature of 25° C.—Amer. Journ. Pharm., April, 1910, 167–175.

Celery Oil—Constituents.—While engaged in preparing sedanolide and sedanonic acid, two constituents of celery oil discovered by Ciamician and Silber in 1897 (see Proceedings, 1898, 976), Schimmel & Co. took the opportunity of examining in detail the remaining constituents, using an oil of their own distillation, which possessed the following constants: \( d_{15}^0 \) 0.846, \( a_2 + 67^0 51' \), \( n_{D_{20}} \) 1.48566. When distilled in vacuo about 60 per cent. passed over at the boiling-point of the terpenes, then followed an intermediate fraction of about 3 per cent. water, after which about 15 per cent. passed over between 110° and 130° C. (9 mm.) and 8 per cent. between 175° and 202° C. (9 mm.) The residue of distillation was 10 per cent. The results of the research show that oil of celery consists of not less than 60 per cent. of hydrocarbons, that is to say, 60 per cent of \( d \)-limonene and about 10 per cent of \( d \)-selinene, a bicyclic sesquiterpene not previously observed in essential oils. Alcohols are present in the oil to the extent of 2.5 to 3 per cent. From the portions with a high boiling point which had already been examined by Ciamician and Silber, from 2.5 to 3 per cent. of pure sedanolide and 0.5 per cent. of sedanonic anhydrideride were isolated.—Schimmel's Semi-An. Rep., Apr., 1910, 32–35.

Oil of Celery Seed—Yield, Characters and Constants.—John Swenholt obtained by steam distillation from 21292.8 Gm. of celery seed (lifeless) 521.0 Gm. (2.446 per cent.) of volatile oil, which was collected in two portions as follows: The portion passing over during the first twenty minutes,
amounting to 256.0 Gm.; the remaining portion, amounting to 265.0 Gm., which passed over more slowly, requiring several days of interrupted distillation. These two oils, designated respectively “light oil” and “heavy oil,” were very different. The first oil was light-colored and possessed a limonene-like odor, while the second oil was of a yellowish color, possessed a distinct odor of celery and was heavier. Portions of the two oils were subsequently mixed in the proportions obtained (100 Gm. of lighter oil and 103.5 of the heavier), for the purpose of examination, which resulted as shown in the following table:

<table>
<thead>

</tbody>
</table>

After standing for eight months the light oil still had a faint celery odor, whereas the heavy oil had lost its agreeable odor and smelled like a resinified turpentine oil. The mixed oil had a strong and pleasant celery odor. The specific gravities of all three oils were redetermined and show an increase in each case, as here recorded:

Oil of Chamomile—Two Distinct Oils in the Flower.—There are, as is well known, plants containing different oils in different parts, although all the oils are formed in schizo-lysigenic cells, and are therefore built up in a similar manner. In the chamomile flower, however, essential oil is formed in two entirely different parts, which differ from each other with regard to the oil cells. This fact has been taken by A. James as the starting point of a study on the essential oil of chamomile (Matricaria ? Rep.). The hollow calyx of this composite flower contains, at the part where the leaves are attached, a wreath of collateral bundles of cells, and in front of the phloëm of these are schizogene structures containing a secretion. The fruit-whorl and the stem of the flower is provided with hairs which secrerate oil. These hairs consist of two rows of cells, showing the character-
istic type of the glands of the compositae. In both containers, owing to
the position of the secerning cells, the oil is formed centrifugally. The
author has distilled both oils separately, obtaining from 4 Kgm. of pure
flowers 14 Gm. of oil (≈ 0.35 per cent.), and from 1 Kgm. of pure calices
5.1 Gm. of oil (≈ 0.51 per cent.).

The oil from the pure flowers possessed the familiar deep blue color of
chamomile oil, was viscous at the ordinary temperature, and showed the fol-
lowing constants: Sp. gr. at 15° C., 0.954; opt. rotation, ±0°; nD 21°,
1.363734; sapon. number, 74.7.

The oil from the pure calices, also viscous at the ordinary temperature,
was faintly green and turned yellow in a few days. It had the sp. gr. at
15° C., 0.949; opt. rotation ±0°; nD 21°, 1.363716; sapon. no. 33.7.—
(1909), 585.

Chamomile Oil—Distinct Oils in the Florets and Receptacle.—A. Jama
has made the interesting observation that chamomile flowers (Matricaria
chamomilla) contain two distinct volatile oils, the florets yielding a blue
oil while the receptacle yields a faint greenish volatile oil, changing
to yellow-brown after a few days. The distinguishing characters and con-
stants are shown in the following:

<table>
<thead>
<tr>

The author is inclined to the belief that the transient greenish color of
the oil from the flower receptacles is due to the unavoidable presence of
some of the petals, or fragments of them during distillation. He finds,
moreover, that the blue oil from the petals does not change its color
readily unless the oil is contaminated with some of the oil of the recep-
tacles. The blue oil retains its beautiful color for a long time unchanged
when exposed to direct light, but when mixed with an equal quantity of
the brown oil, it rapidly changes and also acquires a brown color. On
saponification the blue oil retains the odor of chamomile unimpaired,
whereas the receptacle oil loses it completely and acquires instead an
odor resembling that of lavender.—Apoth. Ztg., xxiv (1909), No. 65,
585-586.

Oil of Champaca Flowers—Preparation in the Philippines.—According
to Bacon experts in the Philippines esteem the yellow variety of champaca
flowers above the white, and maintain that it has the finest odor of any flower in the archipelago. An attempt made by Bacon to obtain oil from the flowers by steam distillation was a failure, only a very small quantity being obtained and its odor did not much resemble that of the flowers; but an oil of excellent and intense odor was obtained by macerating the flowers in paraffin oil for 24 hours and treating the oil with absolute alcohol—the same paraffin oil being used repeatedly for the extraction of the flowers. The author proposes to continue his experiments, using volatile solvents in place of paraffin oil. The champaca tree can be raised easily from the seed and bears as early as the third year.—Schimmel's Semi-An. Rep., Octob., 1909, 38; from Philippine Journ. of Sc., 4 (1909), A, 131.

*Cinnamomum* Oil—Constituents and Constants.—According to S. Keimatzier, a yellowish-brown oil, obtained in the amount of 0.8 per cent. from the flowers of (?) *Chrysanthemum sinesis var. japonicum* (locally known as "Rionō-Kiku"), contains i-camphor, of which body 40 Gm. were isolated by the freezing-out process from 250 Gm. oil. The camphor was identified by means of its oxime (m. p. 116 to 117°, inactive), para-camphoric acid (i-camphoric acid) m. p. 202°, and its β-bromo derivative (m. p. 61°). The oil which was left behind after the removal of the camphor still contained considerable quantities of i-camphor. This oil had the following constants: d\textsubscript{150} 0.9304, [\alpha]_D + 12° 4', acid no. 0, ester no. 0. In the fraction with the lowest b. p. 1-camphene could be detected and was identified by conversion into isoborneol.—Schimmel's Semi-An. Rep., Oct., 1909, 38; from Journ. Pharm. Soc. Japan, 1909, No. 326, 1.

Cinnamon Oils—Difference in Composition According to Source.—In an exhaustive article on the distribution and cultivation of the cinnamon tree, Coyle mentions that in the case of *Cinnamomum Currie*, Bl., which yields the Chinese cinnamon bark, all parts of the tree yield an almost identical volatile oil, containing 75 to 90 per cent. cinnamic aldehyde, whereas in *Cinnamomum Zeylanicum*, Nees, the oils differ according to the part of the plant from which they have been prepared—the oil from the bark and branches being characterized by its content of cinnamic aldehyde, that from the leaves by eugenol, and that from the root-bark by camphor. The author distinguishes a third species in *Cinnamomum Loureirii*, Nees, which furnishes the cinnamon used in Japan. The oil from the root bark of the plant contains, besides cinnamic aldehyde, a terpene with a lavender-like odor. The oil exported from Tonquin and Annam is said to be derived from *C. Loureirii*.—Schimmel's Semi-An. Rep., October, 1909, 38; from Journ. d'Agriculture tropicale, 9 (1909), 164.

*Cinnamon-bark Oil—Distinction from Cassia-bark Oil and Cinnamic Aldehyde.—Experiments recorded by Charles Alexander Hill and illuminated by a number of tables, pointed out that cinnamon-bark oils, genuine and possessed of a true and delicate cinnamon flavor, are characterized
by and distinguished from cassia oil and cinnamic aldehyde by: (1) a low specific gravity (below 1.04); (2) a low refractive index (below 1.58); (3) a low aldehyde-content (below 65 per cent.), and by affording a green color with ferric chloride. Furthermore, it was shown that a high proportion of cinnamic aldehyde raises both the specific gravity and the refractive index, and that adulteration with leaf oil would, of course, result in an unduly high proportion of eugenol.—Chem. & Drugg., June 25, 1910, 59.

Citronella Oil—A Distillate Produced in the Malay Peninsula.—B. J. Eaton, Government Chemist of the Federated Malay States, has examined a locally distilled citronella oil, which came from Perak. In its general behavior this oil corresponded with the Java oil. The color was pale yellow, the total oxygenous content was 82.4 per cent., of which 27.7 per cent. was geraniol and 54.7 per cent. citronellal; sp. gr. at 15.5° C., 0.8890; soluble in its own weight and more of 80 per cent. alcohol.—Schimmel's Semi-An. Rep., Octob, 1909, 43.

Citronella Oil from German New Guinea—Inferior Geraniol Content.—In continuation of the information given by Schimmel & Co. last year regarding citronella oil from German New Guinea (see Proceedings, 1909, 310), they now give the following constants of a similar oil, since received from the German Colonies in the Southern Pacific: d_{150} 0.8964, a_0—1°20', geraniol and citronellal content 78 per cent, soluble in its own volume and over of 80 per cent. alcohol. Although this oil also resembles the Java oil in its general characteristics, its geraniol content is rather less, and falls below that of the sample examined last year by about 8 per cent.—Schimmel's Semi-An. Rep., April, 1910, 37.

Oil of Citronella from Comoros—Constants.—Roure-Bertrand Fils have determined the following constants in an oil of citronella produced on the Comoro Islands, which, although possessing a fine odor, was completely insoluble even in absolute alcohol: Sp. gr. at 15° C., 0.8922; opt. rot.,—0°52'; insoluble, even in absolute alcohol; aldehyde (determined by the bisulphite method), 80 per cent.—Rep. of Roure-Bertrand Fils, October, 1909, 42.

Java Citronella Oil—Citral a Constituent.—Some years ago (see Proceedings 1900, 749) Schimmel & Co. showed that Java oil contains citronellal, geraniol and d-citronellol, and subsequently proved the presence of methoxyl groups in the oil, which points to the occurrence of methyl-eugenol. So far no further constituents had been made known, but they have now succeeded in isolating a previously unknown constituent from Java citronella oil, namely, citral, which is, however, present only in small amount—computed at about 0.2 per cent.—Schimmel's Semi-An. Rep., April, 1910, 37.

Citronella Oil—Possibly a Protection Against the Tsetse Fly.—Schimmel
& Co. direct attention to an article by A. W. G. Bagshaus, in which it is stated that the tsetze-fly (Glossina palpalis), so much feared as the medium by which the sleeping sickness is conveyed, has a pronounced dislike of citronella grass; hence an extension of the cultivation of this grass would afford an additional means of combating this dangerous insect. Seeing that the fly's aversion to this grass is probably entirely due to the oil present in the citronella grass, the advisability of experiments as to how far it would be possible to protect man and beast by means of citronella oil is suggested.—Schimmel's Semi-An. Rep., Oct., 1909, 44.

Oil of Cloves—Sophistication with Camphor Oil Fractions.—Schimmel & Co. describe sophisticated oil of cloves, expressly represented as having been distilled from cloves, which at first seemed normal, but on closer examination was found to contain in the phenol content, besides eugenol, impurities with an odor reminding of creosote, while the portions which were freed from phenol contained an abundant quantity of safrol. The examination was undertaken because of the high optical rotation and deficient degree of solubility. Evidently this oil is a simple concoction, made up principally of suitable camphor oil fractions.—Schimmel's Semi-An. Rep., April, 1910, 43.

Oil of Cloves—Newly-Discovered Constituents.—H. Masson describes a series of newly-discovered constituents in clove oil, embracing the following: Methyl-n-amyl carbinol (Heptanol-2); furfur-alcohol; methyl-n-heptyl carbinol (nonanol-2); benzyl-alcohol; methylfurfur-alcohol; a-methylfurfurol; dimethylated furfurol; methyl salicylate. The existence of the last named had heretofore not been proved with certainty.—Schimmel's Semi-An. Rep., April, 1910, 44; from Compt. rend., 149 (1909), 630 and 795.

Coniferous Volatile Oils—Constants of Authentic Specimens.—John Swenholt communicates the results of the preparation and examination of four different coniferous oils obtained by distillation with cohabation from authentic specimens of leaves and branches received from Colorado. The quantities of oils so obtained were too small to permit a complete examination, and the constants determined must therefore be accepted with considerable allowance. The leaves and branches of

Pinus Murrayana yielded about 5 Cc. of oil with an agreeable odor, devoid of terebinthinate characteristics. Its saponification number was 51.87, corresponding to 18 per cent. of ester when computed as $C_{16}H_{17}-OCOCH_3$.

Picea Englemanni, leaves and branches, yielded about 15 Cc. of oil having a decided camphoraceous odor. Sp. gr. 0.8950; $a^p$ in 50-Mm. tube = $+ 1^\circ 55' 38''$; sapon. number, 24.15, corresponding to 8.5 per cent. of ester.

Pinus Edulis yielded about 10 Cc. of oil having an odor which, aside
of a slight reminder of petroleum, was rather agreeable and devoid of terebinthinate characteristics. Sp. gr. 0.8653; \( a_0 \) in 50-Mm. tube = 

\[-3^\circ 36'58''\]; sapon. number, 17.55, corresponding to 6 per cent. of ester.

*Pinus Flexilis* yielded about 10 Cc. of oil. Odor slightly camphoraceous. Sp. gr. 0.8670; \( a_0 \) in 50-Mm. tube = \(+4^\circ 0'28''\); sapon. number, 43.14, corresponding to 15 per cent. of bornyl acetate.—Midland Drugg. & Pharm. Rev., Dec., 1909, 611-612.

Pine Needle Oil—Influence of Method of Distillation.—Fifteen years ago Schimmel & Co. reported on an oil from *Pinus silvestris* L., which had been distilled from green pine needles collected in winter. A large parcel of branches from *Pinus silvestris* received a considerable time ago, has now afforded them an opportunity of once more distilling this oil, which is almost unknown in commerce, and at the same time of making experiments with a view of ascertaining in how far the mode of distillation affects the product obtained. The material was distilled partly dry and partly after having been soaked with water; the separate fractions as well as the oil from cohabation being each examined separately. Finally all the parts of the same oil were poured together and compared with a sample of an oil which had been obtained by one continuous process of distillation. The table below gives a review of the results obtained:

<table>

True Lebanon Cedar Oil—Preparation and Characters from Authentic Wood.—In 1892 Schimmel & Co. had described in their April Report an oil which they at the time believed to be the distillate of authentic Leba-
OIL OF TURPENTINE.

307

non cedar wood, but which was subsequently discovered to be wood derived from a species of Juniperus. They are now in position to give some particulars of a really authentic oil from the wood of Cedrus Libani, Barr. (Pinus Cedrus, L.; Abies Cedrus, Poir.; Larix Cedrus, Mill.). The authentic wood yielded about 3 per cent. of a lemon-yellow oil of a pleasant balsamic odor, reminding at the same time of methylpeptenone and thu-jone. This oil possessed the following constants: \( d_{20}^\circ \), 0.9427; \( a_2 = +80^\circ \) 20'; \( n_0 \), 20°, 1.51254; acid number, 0.5; ester number, 3.0; ester number after acetylation, 19.8; soluble in 5 to 6 vols. of 95 per-cent. alcohol.—Schimmel's Semi-An. Rep., October, 1909, 132.

Oil of Juniper Berries—Oxygenous Constituents.—As known, the principal constituents of juniper berry oil are the hydrocarbons pinene and cadinene. Schimmel & Co. have now made an examination of the oxygenous compounds of this oil, which has shown them to consist in great part of the alcohol terpineol—the same as occurs in the oils of cardamom and marjoram. Another alcohol, however occurs in addition to terpineol, but in far smaller proportions. This alcohol has the following constants: b. p. 105° to 110° C. (8 Mm.) 218° to 226° C. at atmospheric pressure; \( d_{15}^\circ \), 0.4746; \( a_0 = 0^\circ \) 1.30; \( n_{D20} \), 1.48248. It combines readily with phthalic acid anhydride, and was isolated from the fractions boiling between 95° and 130° C. in the form of the acid phthalic ester. In its odor the alcohol reminds of geraniol and borneol, and it is probably a mixture of various alcohols. Besides the compounds enumerated, juniper oil contains bodies of a particularly characteristic odor, most of which occur in small proportions in the fraction boiling between 72° and 88° (8 Mm.).—Schimmel's Semi-An. Rep., October, 1909, 71–73.

Oil of Turpentine—Improved Method of Examination.—Paul Nicolardot and Louis Clement urge the use of fractional distillation under reduced pressure in place of ordinary distillation in the examination of oil of turpentine for adulterants. By this means the optical rotation of the successive fractions of the pure product is not altered nor the non-volatile residue increased, while the operation is completed in twenty minutes. The presence of petroleum spirit is indicated by the increasing rotatory power of the first fractions, while a sharp drop in rotatory power in the last fraction is indicative of resin oil. On exposure to light and air, turpentine undergoes oxidation, and its rotatory power is diminished when examined several hours later, but this diminution is still more marked if resin-products have been added. Other portions of the same sample kept in the dark with like conditions as to temperature and evaporation do not undergo appreciable change except in the case of samples containing petroleum spirit, in which the evaporation raises the rotatory power.—Chem. & Drugg., April 9, 1910, 46; from Ann. de Chim., Febr. 15, 1910, 53.

Oil of Turpentine—Detection of Petroleum.—M. Mansier observes that
during recent years the high price of oil of turpentine has led to its being adulterated with light petroleum, and moderate quantities of the latter are very difficult to detect. A useful test for this purpose is afforded by the bromine-absorbing capacity of the sample; this must be determined under definite fixed conditions, as the amount of bromine absorbed by pure oil of turpentine varies with varying conditions. The following method was found to give satisfactory results:—1 Cc. of oil of turpentine is put into a stoppered flask with 5 Cc. of chloroform, and 50 Cc. of 3 per cent. bromine water is then added and the whole well shaken; more bromine water is then added a few drops at a time, shaking after each addition, until the chloroform layer retains a slight yellow color lasting for one minute after shaking. Tested in this way, 1 Cc. of pure oil of turpentine absorbs 1.69 Gm. of bromine; if this is contained in 60 Cc. of bromine water, turpentine containing 10 per cent. of petroleum would only use 56 Cc. of the latter: if it contained 20 per cent. 49 Cc., and if 50 per cent. 32 Cc. The bromine water that is used must be freshly prepared, and its exact strength must be determined immediately after the test on the turpentine. Pharm. Journ. and Pharmacist, Jan. 1, 1910, 7; from Rép. d. Pharm., Oct. 10, 1909, 454.

Oil of Turpentine—Distinctions of that Distilled from the Oleoresin and from the wood.—S. S. Jacobs finds that no essential difference is presented in the specific gravity and refraction index of oils of turpentine distilled from the wood and from the oleoresin, and that the optical rotation of either may be to the right or left, dependent on the source of the material. The chief point of difference in the two oils appears to exist in the boiling point of the fractions, the oil from oleoresin ceasing to distil at 165° C., while the oil from wood continues to distil up to 185° C., leaving in either case a very small residue; the characteristic odor peculiar to each of the two oils affording the only other distinctive difference.—Amer. Journ. Pharm., May, 1910, 232.

Oil of African Copaiba—Composition and Constants.—H. von Soden has published the results of an investigation into the composition of an oil from African copaiba. By passing hydrochloric acid into the ethereal solution he obtained from the oil (constants: d 0.920; \(a_b + 16^\circ = 30^\circ\); ester number, 5. 6; ester number after acetyl., 10) a hydrochloride, m. p. 116° to 119° C. (\(a_b - 3^\circ\) in 10 per cent. benzene solution). The hydrocarbon regenerated therefrom had the following constants: b. p. 274.5 to 276° C. (743 Mm.); d. 0.928; \(a_b = 94^\circ\). These properties agree with those of l-cadinene. It was not possible to arrive at a conclusion as to the particular sesquiterpene which occurs in the oil. Apparently, however, the conditions are somewhat similar to those which prevail in West Indian sandalwood oil, of which Deussen converted the dextrorotatory sesquiterpene into l-cadinene by way of the hydrochloride.—Chem. Ztg., 33 (1909), 428.
Referring to the above, Schimmel & Co. give the results of a recent investigation of the oil of African copaiba, which agree with those obtained by von Soden.—Schimmel's Semi-An. Rep., October, 1909, 46.

Coriander Oil.—Constituents.—Schimmel & Co. observe that heretofore only d-pinene and d-linalool have been known positively as being constituents of coriander oil. They have now made a comprehensive examination of an oil distilled in their laboratories from ripe coriander seed, having the following constants: sp. gr. at 15°C., 0.8735; opt. rot., +10° 24'; refract. index, 20° C., 1.46287; ester no. 20. 22. By this investigation, the details of which are briefly described, they have now determined the following bodies as being constituents of coriander oil: d-α-pinene, β-pinene, phellandrene (?), cymene, dipentene, α-terpinene, γ-terpinene, terpinolene (?), n-decyclic aldehyde, d-linalool, geraniol, l-borneol, and acetic esters of these alcohols.—Schimmel's Semi-An. Rep., October, 1909, 47-49.

Cumin Oil.—Constituents.—Schimmel & Co. report the results of an investigation into the constitution of cumin oil (Cuminum Cymium, L.). This oil has long been known as containing cuminic aldehyde as the principal constituent, but is said also to contain cymene, and a terpene C_{10}H_{16}, which Wolpian called hydrocuminene. The oil examined in the present investigation possessed the following constants: b. p. 165°-380° (754 mm.), d_{30} 0.921, α_p +4° 20' n_{D20} 1.50784. The hydrocarbons were separated from the fractions with higher boiling points by fractionation in vacuo. The fractions possessing a b. p. of over 80° (10 mm.) were shaken up with bisulphite, only small portions being left unaffected by this reagent. The examination therefore fell under the following heads: — I, The hydrocarbon fraction; II, the products reacting with bisulphite; III, the portion not reacting with bisulphite. The results showed that the hydrocarbon fraction (I) consists for the greater part of p-cymène, together with small quantities of d- and l-α-pinene, β-pinene, β-phellandrene and dipentene. The aldehyde fraction (II) contained cuminic aldehyde (cuminol) in a state of great purity, and probably small proportions of hydrogenated cuminic aldehyde. The small portion not affected by bisulphite (III) consisted principally of cuminic alcohol and of a body melting at 97°-107° (3 mm.), which requires further examination.—Schimmel's Semi-An. Rep., Oct., 1909, 49-53.

Galician Dill Oil.—Sophistication with Oil of Fennel.—Schimmel & Co. call attention to a sample of dill oil received some time ago, which was suspicious on account of the high specific gravity and too slight optical rotation and high refraction index. Its solubility in 80 per cent. alcohol also left something to be desired, as the solution did not become quite clear. The first impression was that the oil had been distilled from the herb, but this was abandoned by the absence of phellandrene in the oil,
and subsequent examination showed the oil to have been grossly adulterated. The presence of liberal proportions of anethol showed without doubt that the adulterant was oil of fennel. Schimmel’s Semi-An. Rep., April, 1910, 47.

Eucalyptus Oil—Australian vs. United States is the subject of an interesting paper by Edward S. Binz, in which he points out the superiority of the American oil, obtained from the cultivated Eucalyptus globulus, over the Australian oils, which are mixed oils obtained from different species and usually contains much less of its important constituent eucalyptol. The paper appears in the “Proceedings,” 1909, 1054–1055.

African Eucalyptus Oil—Characters and Constants.—Schimmel & Co. have received from the Transvaal and examined a sample of eucalyptus oil which, judging by the odor and by its content of cineol, might have been a crude globulus oil. Its constants also lie within the limits laid down for oils of this class: \( d_{15}^0 0.9236, a_0 + 1^\circ 45', d_{20}^0 1.46337 \); it was free from phellandrene, soluble in 2.8 vols. of 70 per cent. and more alcohol, and had a cineol-content of about 65 per cent.—Schimmel’s Semi-An. Rep., Octob., 1909, 67.

Ficaria Oil—Yield and Characters.—Under the name “ficaria oil,” Haensel’s Report describes a volatile oil which was obtained by distillation in the quantity of 0.02 per cent. from the herb of Ranunculus ficaria. It is a dark brown fluid having a tobacco-like odor and when filtered from a solid deposit had the sp. gr. 0.9101 at 24° C. When heated with ammoniacal solution of silver oxide, it forms a mirror, indicating the presence of an aldehyde. The boiling-point is between 150° and 310° C., but shows no constancy. A solid acid, identified as palmitic acid, was isolated.—Pharm. Ztg., lv (1909), No. 83, 822; from Heinrich Haensel’s Report.

Oil of Hyacinth—Preparation and Properties.—C. J. Enklaar obtained the volatile oil of hyacinth by extracting the fresh flowers with cold benzol, distilling off the solvent and purifying the crude oil by treatment with diluted alcohol and petroleum ether, by which fixed oil and wax were almost completely removed from it. The very small quantity of oil so obtained had a sharp and disagreeable odor in its concentrated state, but when largely diluted gave the odor of the flowers to perfection. Chemically it gave no ketone reaction and showed saturation in its behavior with potassium permanganate. The presence of benzyl alcohol, benzyl benzoate and a non-nitrogenous, fluorescent constituent were determined.—Pharm. Ztg., lv (1910), No. 30, 305; from N. Chem. Zentralbl., 1910, No. 8.

Hyssop Oil—Confirmation of Constituents—Referring to their very exhaustive investigation of the constituents of hyssop oil previously reported (see Proceedings, 1908, 325), in which Schimmel & Co. had demonstrated that this oil contained, in addition to \( \beta \)-pinene, an active ketone, \( l \)-pino camphone, which had hitherto not been observed, their chemists have
made a new series of experiments, with the particular object of absolutely identifying the acid \((l\text{-pinonic acid})\) existing in the oil and resulting when the ketone is oxidized with permanganate. These experiments conclusively show the acid contained in oil of hyssop to be \(l\text{-pinonic acid}\), and the ketone \(l\text{-pinocamphone}\). This examination became necessary, because Tiemann had obtained by dry distillation of \(a\)-dihydroxydihydro campholenic acid, an acid of the composition \(C_{10}H_{16}O_3\), which he regarded as \(l\)-pinonic acid, but which possessed quite different properties.—Schimmel's Semi-An. Rep., Oct., 1909, 68–70.

**Oil of Hyptis Suaveolens, Poit—Yield and Properties.**—According to Bacon, *Hyptis suaveolens*, Poit, a Labiatae known in the Philippines in the Tagal language by the name of *sub-cabayog*, yields a very small proportion of a green-colored oil with a strong odor of menthol, which in fact, as was shown by further examination, constitutes the chief constituent of the oil. The slight oil-content (200 kilos material produced only 27 Gm. or 0.0135 per cent.) excludes the possibility of distillation on a large scale. Schimmel & Co., however, have previously reported that the yield of oil from the same plant in Java was very considerably higher, namely, 1 per cent.—Schimmel's Semi-An. Rep., October, 1909, 68; from Philippine Journ. of Sc., 4 (1909), A. 130.

**Kryptomeria Oil—Constituents.**—H. Kimura has obtained and describes the volatile oil obtained from the wood of *Kryptomeria japonica*, the "Sugi tree" of Japan, used for 1000 years or more to construct the barrels for storing rice wine, imparting to it a peculiar flavor. Previous examinations of this oil by Kimoto, and by Kamatsu, have not yielded satisfactory information regarding the constituents of this oil. Kimura now finds it to be composed of 60 per cent. of the sesquiterpenes cadinene and suginene, and of 4 per cent. of an alcohol having the formula \(C_{10}H_{20}OH\). The constitution of the latter requires further investigation.—Pharm. Ztg., lv (1909), No. 82, 813.

**Oil of Lantana Camara, L.—Yield and Properties of.**—According to Bacon, *Lantana camara*, L., a pleasantly odorous plant, flourishes with such extraordinary profusion in the Philippines that it would undoubtedly pay to cultivate it. The yield of oil from the leaves appears to vary greatly according to age, season, etc., as from two parcels of raw material one weighing 60 and the other 110 kilos, the oil-yield was 0.07 and 0.245 per cent. by volume respectively. The oil is pale yellow, with an odor reminding of sage, and has the following constants: \(d_4^{20^\circ} 0.9132\), \(a_{20^\circ} + 11.5^\circ\) C., \(n_{D30} 1.4913\). Subjected to fractionation, 50 Gm. oil resulted as follows: 22 Gm. b. p. 125\(^\circ\) to 130\(^\circ\) C. (12 Mm.), \(n_{D30} 1.4892\); and 24 Gm., b. p. 130\(^\circ\) to 140\(^\circ\) C. (11 Mm.), \(n_{D30} 1.4970\). In this connection, Schimmel & Co. mention that the West Indian oil of *Lantana odorata*, L., described by them last year (see Proceedings, 1909, 318), agrees
closely in its properties, with the exception of the rotation, with those ascertained by Bacon for oil of Lantana camara, L.—Schimmel's Semi-An. Rep., October, 1909, 73; from Philippine Journ. of Sc., 4 (1909), A, 127.

Oil of Lemon—Terpene Constituents.—In view of the abundance of material brought to light by the recent researches into the chemistry of the terpenes, Schimmel & Co. considered it timely for a fresh investigation of the terpene mixture contained in oil of lemon, the results of which they now publish. After removing the oxygenated constituents of the sample under examination by treatment with dilute alcohol, the residual portion was found to possess the following constants: $d_{15}^\circ 0.8524, a_p + 66^\circ 81, n_{d20}^\circ 1.47078$. Fractional distillation yielded two principal fractions, one boiling at 160 to 178°, the other at 250 to 278°. The first consisted of terpenes, the second, and by far the smaller in point of quantity, of sesquiterpenes. The systematic investigation of these fractions shows that, in addition to d-limonene, long recognized as the principal constituent, the only body which occurs in the oil in relatively considerable proportions is 1-3-pinene. Of 1- and i-a-pinene, 1-camphene, 3-phellandrene and 3-terpinene only small quantities were discovered; p-cymene could not be detected at all. The sesquiterpenes only form a very inconsiderable proportion of the oil, which probably, besides bisabolene, also contains cadinene.—Schimmel's Semi-An. Rep., Octob., 1909, 62-65.

Lemongrass Oil—Production in the Philippines.—According to Bacon, a variety of grass which from the characteristics of the lemongrass oil it produces, is regarded as Andropogon citratus D. C., is cultivated to a small extent in the Philippines, although it occurs everywhere throughout the Archipelago, both as a garden-plant and in the wild state, and grows in special profusion in the highlands of the province of Benquet. In the Tagalog language this oil-grass is called by the name given to it in 1635 by the Spanish Jesuit Juan Eusebius Nürnberg, who was the first to describe it, viz., tanglat, or more accurately, tanglad. Other native names for the plant are salai and balyoco; its Spanish name is Paja de Meca. At the present time the oil is not distilled commercially. Bacon points out, quite justly, that under the present market-conditions the cultivation of lemon grass would not be profitable, notwithstanding the fact that it grows quickly and produces a rich yield; and he only recommends it as a temporary crop, to be grown until other plantations produce sufficient returns. A grass 4 months old, distilled two days after being cut, produced 0.2 per cent. of an oil with the following properties: $d_{45}^\circ 0.894, a_{d30}^\circ + 8.1^\circ$, $n_{d30}^\circ 1.4857$; citral content, 79 per cent. On the basis of the quantity of grass produced under experimental cultivation, and also of the oil-yield, Bacon estimates an output of from 230 to 300 kilos of oil per hectare, assuming that three crops can be cut annually. As the cultivation is rather ex-
hausting to the soil, the crop must be changed after three years.—Schimmel's Semi-An. Rep., October, 1909, 76; from Philippine Journ. of Sc., 4, (1909), A., 111.

East Indian Lemon Grass Oils—Distillates at Different Stages of Development.—Schimmel & Co. received through the courtesy of Mr. I. H. Burkill some samples of East Indian lemon-grass oils which are especially interesting, because they have all been distilled at various seasons from grass grown in one district, viz., Jalpaiguri. In July, 1909, Mr. Burkill distilled grass before the flowering period, both locally (Ia) and in Calcutta (Ib). Two months later, in September, he again distilled before flowering (II). Finally he distilled a grass cut while in flower, first using the flowers only (III) and, for another experiment, the leaves only (IV). Hence, had the distillates differed in their characteristics, it would have been possible to draw definite conclusions as to the condition of lemon-grass according to the stage of development of the raw material. No differences of any importance, however, were discoverable in the oil from the flowers and the leaves; these samples showed no material divergence from those prepared from herb before flowering, and no such differences were observable among the various oils distilled before flowering. The oil from leaves is a little richer in aldehydes and rather heavier than the oil from flowers, but the few investigations which have been made so far do not warrant any final conclusions. The constants of the various oils are enumerated in the table below:

<table>

</table>

All the five samples gave clear solutions only at first, even with 90 per cent alcohol; when diluted the solutions turned strongly opalescent.—Schimmel's Semi-An. Rep., April, 1910, 73.

West Indian Limette Oil—Properties.—Schimmel & Co. observe that the literature of essential oils contains only sporadic data concerning the
properties of West Indian limette oil obtained by hand-pressing (hand-
pressed oil of limette; hand-pressed lime oil; ecuelled essence of limes),
and that it is therefore probable that in many quarters uncertainty prevails
as to the properties which the oil should possess. They therefore believe
it to be generally serviceable if they mention the properties observed by
them in the case of a warranted pure quality of this oil, but in doing so
wish it to be understood that pure oils may occur which vary somewhat in
one or another of their constants: \(d_{50} &= 0.878\) to \(0.901\), mostly between
0.880 and 0.884, \(a_{D} + 32^\circ 50'\) to \(+37^\circ 30'\), \(a_{D}\) of the first 10 per cent of
the distillate rather higher, or at most 4° lower than \(a_{D}\) of the original oil
\(n_{D50} = 1.482\) to 1.486, acid no. up to 3.0, ester no. 18 to 30; residue of
evaporation 10 to 14 per cent., in one instance 17.8 per cent. The oil
gave a cloudy solution in 4 to 10 vols. of 90 per cent. alcohol, with separa-
tion of wax- or paraffin-like constituents.

Oil obtained by distillation (distilled oil of limette; distilled oil of limes;
distilled lime oil) as well as the Italian variety of oil obtained by pressure
hardly count as commercial articles.—Schimmel's Semi-An. Rep., Octo-
ber, 1909, 77.

Cayenne Linaloe Oil—Constituents — Roure-Bertrand Fils report the
following constituents in oil of linaloe of their own distillation at Cayenne:
Methylheptenone, traces; l-linalool, 90.5 per cent.; d-terpineol 5.3 per
cent.; geraniol, 2.4 per cent.; nerol, 1.2 per cent. The oil had the sp. gr.
0.8721 at 20° C.; \(a_{D} = -12^\circ 56'\); \(n^d_{20} = 1.4655\).—Rep. of Roure-Ber-
trand Fils, Oct., 1909, 41.

Oil of Linaloe-Seed—A Substitute for Oil from the Wood.—The
"Chemist and Druggist" observe that the oil from linaloe-seeds is now
being imported on a commercial scale. The linaloe trees are now rapidly
disappearing from the Mexican forests in consequence of reckless ex-
plotation, and it is with the object of saving the trees that the oil is now
being distilled from the seeds. It is not yet ascertained whether the
seeds will yield a sufficient quantity of oil to supply the demand. It is
stated that the oil distilled from the seeds is not different as regards odor
from good essential oils distilled from the wood. The principal difference
lies in its optical rotation, the other characters being almost identical with
the wood oil, as shown by the following figures:

Fractional distillation showed the presence of methyl heptenone (boiling-point, 173° C.; specific gravity, 0.853; refractive index, 1.440; melting-point of semicarbazone, 137° to 139° C.), linalol (specific gravity, 0.864; refractive index, 1.4645; optical rotation, +5° C. 30'); melting-point of phenyl urethane, 65° to 66° C.), geraniol (boiling-point, 229° C.; melting-point of diphenyl urethane, 81° C.), nerol (melting-point of urethane, 51° to 52° C.), and terpineol (melting point of phenyl urethane, 111° to 112° C.).—Chem. & Drugg., Jan. 29, 1910, 152.

Oil of Mentha Silvestris from Ceylon—Properties.—Schimmel & Co. have examined a sample of an oil of Mentha silvestris, L., prepared in Cyprus, and received from the Imperial Institute in London, which was found to possess the following properties: d_{15}^0 0.9701, a_{D} + 31° 30', n_{D20}^0 1.49544, acid no. 2.4, ester no. 20.9, ester no. after acetyl. 171.4, soluble in 3 vols. of 70 per cent. alcohol; (the diluted solution showed slight opalescence); faintly mint-like odor; yellow color. It is obvious that the saponification number of 171.4 after acetylation of the oil cannot in this case be indicative of the menthol content, which, judging by this factor, should have been 54.8 per cent.; for as a matter of fact the sample contained but little menthol. The mint-like odor was chiefly due to the presence of pulegone, of which the oil contained 40 per cent. (isolated with neutral sulphite of sodium). In addition to this a phenol (probably carvacrol) could be detected, from which it is to be supposed that this, also, would become esterified and would help to swell the acetylation value. Owing to the simultaneous occurrence in it of menthol, pulegone and a phenol, the oil cannot be used either as peppermint oil or as European pennyroyal or origanum oil. It is differentiated from oil of peppermint by its much higher specific gravity and by its pronounced dextrorotatory power.—Schimmel’s Semi-An. Rep., April, 1910, 123.

Oil of Monarda Didyma, L.—Properties as Obtained from Half-faded Flowers.—Supplementary to a previous report on two oils of Monarda didyma, L. (see Proceedings, 1909, 322), the one from the herb, the other from half-faded flowers, Schimmel & Co. now report on a distillate obtained from half-faded flowers during the past summer. They found this oil, obtained in a yield of 0.26 per cent., to possess constants similar to those observed in that distilled a year earlier: d_{15}^0 0.8740, a_{D}—15° 45', n_{D20}^0 1.46743, acid no. 4.9 ester no. 5.6, soluble in 3 vols. and over of 70 per cent. alcohol; after the addition of 6 vols. of alcohol paraffin began to separate out in abundance. The color of the oil was lemon-yellow, the odor peculiar, resembling ambergris, and rather faint.—Schimmel's Rep., October, 1909, 80.

Oil of Monodora Grandiflora—Constituents and Constants.—R. Leinbach has obtained from the seed of Monodora grandiflora, a plant growing wild in Africa, about 30 per cent. of a soluble oil, constituting a mobile
pale yellow liquid, having the odor of cymene and a taste, at first aromatic, afterwards bitter. This oil possessed the following constants: $d_{45}^0 = 0.8574$; $a_{D15}^0 = 46^\circ 15^\prime$; acid number, 3.9; sap. number, 7 to 12. At room-temperature one part of the oil is soluble in $3\frac{1}{2}$ parts of 90 per-cent. alcohol. In the fractions with the lower boiling-points ($64^\circ$ to $66^\circ$ C.), which consisted for the greater part of hydrocarbons of the formula $C_{10}H_{16}$, the author found $\beta$-phellandrene, and it is highly probable that they contain also small quantities of camphe. In the fractions boiling between $70^\circ$ and $85^\circ$ C., $\beta$-cymene was found and identified by being oxidized into hydroxy-isopropylbenzoic acid. In the highest boiling fractions, palmitic acid and most probably a little carvacrol were found, but the major portion consists of a compound, $C_{10}H_{18}O$, constituting a pale yellow oil, to which the aromatic odor of the oil is due. This compound has the sp. gr. at $15^\circ$, 0.9351; op. rot., $-90^\circ 14^\prime$; b. p., 130 to 154$^\circ$ C. These fractions also contain a sesquiterpene, not yet clearly identified, and a solid body (m. p. 160 to 163$^\circ$ C.) of unknown constitution.—Schimmel's Semi-An. Rep., April, 1910, 77; from Wallach Jubilee Publication (1909), 502.

Oil of Morinda Citrifolia—Properties and Constituents.—Several years ago, C. J. E. Lohmann discovered in the fruit of Morinda citrifolia, L., the presence of one of the higher aliphatic acids in conjunction with an ester. This fruit, known locally in Java as Benkulul or Tjiangkudu, yields an essential oil, which was prepared some time ago in Java by A. W. K. de Jong, and has recently been examined by P. van Romburgh. The oil was of a yellowish color, and had a sp. gr. of 0.927 at 13$^\circ$ C. It was cloudy owing to the separation from it of small crystals, which recrystallized from alcohol, melted at 60$^\circ$ C., and, upon analysis, were shown to consist of paraffins. When freed from the crystals the oil was almost entirely soluble in dilute soda-liquor. In the solution capronic (m. p. $-5.2^\circ$ C.; $d_{15}^0 = 0.932$) and caprylic acid (m. p. 15.2$^\circ$ C. $d_{15}^0 = 0.913$) as well as a traces of the higher aliphatic acids, could be detected. In the neutral part of the oil, which only amounted to a few per cent., ethyl alcohol (identified by the b. p. and the iodoform-test); also probably methyl alcohol and alcohols of a fuselike odor, could be detected after saponification. The occurrence of over 90 per cent. of acid in an essential oil is very rare.—Schimmel's Semi-An. Rep., October, 1909, 80; from Koninkl. Akad. van Wetenschappen te Amsterdam, 1909, 17.

Myrtle Oil from Cyprus—Constants.—Schimmel & Co. call attention to myrtle oil from Cyprus which had the following constants: Sp. gr. at $15^\circ$ C., 0.9174; opt. rot., $+8^\circ 11^\prime$; refrac. index at 20$^\circ$ C., 1.46357; acid no. 0.3; ester no., 20.9; ester no. after acetylation, 63.9; soluable in its own volume and more of 80 per cent. alcohol. This oil has most affinity with the myrtle oils from Asia Minor, but up to the present all attempts to introduce such oils commercially alongside of the oils from Spain and the
South of France have been unsuccessful.—Schimmel's Semi-An. Rep., April, 1910, 78.

Palmarosa Oil—Distillation in India.—Mr. J. H. Burkill, of the Indian Museum, Calcutta, communicates to Schimmel & Co. a description founded on his own observation of the manner in which "rusa" or "palmarosa" oil is obtained in the district of Amraoti, province of Berar, India, accompanied by photographs and sketches representing the distilling plant in actual use. Mr. Burkill says that the oil distilling industry about Ellichpur is worked in the following way. The forest lands where Cymbopogon Martini var. Motia grows are leased out to men of substance—generally Mohammedans, who for the most part sub-lease them again piece-meal to men who go out to selected valleys in the Melghat with stills and engaging villagers send some out to cut the grass tops at so much per hundred bundles brought in, and with others set up open-air distilleries on the banks of the streams. There is built first a row of stone fire-places and the cauldrons are set up on them, generally 3 or 4 in a row. The cauldrons are sometimes of iron and sometimes of copper. If they are of copper they are generally somewhat smaller than those of iron and depressed globose; the iron cauldrons are cylindrical and rivetted; they are about 2½ feet in diameter. The top of the iron cauldrons is slightly conical with a central lid. Out of the lid emerges the bamboo elbowed tube by which the distillate passes off. The elbowed tube has a bamboo peg run through it at the angle and is wrapped from end to end in string. From the elbow the longer part is about six feet, the end dipping about 6 inches into receivers, which are generally long-necked, more than a foot in diameter below, not so deep as broad (neck excluded). But sometimes they are without a neck, in which case a pad of cloth on the bamboo closes the mouth. They are generally made of copper. They are placed in the water quite up to the neck. A framework of wood lies in the stream which is generally dammed to deepen the water. Into the interspaces of this framework the receivers fit, being held in place by means of two sticks of wood which are tied on either side of the neck and are placed under the cross bars of the framework. Further, stones are heaped round each receiver to help to keep them under water. The accompanying cut (Fig. 65) exhibits the two kinds of stills, the bamboo conducting tube, and a short-necked receiver.

The stills having been set in place ready for the fire, are never moved, and the distillation is conducted as follows: Supposing that the still or cauldron has just been emptied of a charge, with the lid off and with the fire drawn from below it, a workman standing on the stone walls around the still, measures the depth of the water remaining in it and adds enough clean water to adjust the depth (in a large still) to 10 or 12 inches, whereupon the grass is introduced into the still, packed down, often by trampling so as to get as much as possible into it. According to size the
change will consist of from 100 to 200 bundles of grass, each bundle containing about 300 stems. Next the lid is replaced and the joint luted with a paste of flour of "udid" (*Phaseolus*) and a muddy bandage; the bamboo tube is inserted into the hole in the lid where it fits and is similarly luted in, the fire is started under the still and distillation again begins. The boiling lasts two to three hours (five to six boilings being done in the twenty-four hours), the end of a distillation being indicated by the bubbling of the steam through the increasing distillate, causing a sound which the workmen describe as "titit" and which deepens and becomes what they call "bulbul," when they know it is time to stop the boiling. This is done by removing the fire, throwing cold water over the lid of the still, removing the bamboo tube, and lifting the lid—the pressure of steam at this time being not inconsiderable. In the meantime, the receiver is taken from the stream, and while the men with a hay fork remove the exhausted grass, the master with a spoon takes the oil from the top of the water in the receiver, using a tin funnel to separate it from any water which the spoon brings up with the oil. Table salt to the extent of half a pound is thrown into each still every few days. In some stills lime juice is now

![Method of Distilling Palmarosa Oil.](image-url)
used to help clarify the oil.—Schimmel’s Semi-An. Rep., October, 1909, 88-90.

Oil of Peppermint—New Adulterant.—Ernest J. Parry calls attention to peppermint recently appearing on the market, having all the physical characteristics of genuine oil, except that its solubility is not as good as it should be. From a small sample he succeeded in separating by fractional distillation about 20 per cent. of an oil having a refractive index of about 1.430 and an optical rotation of $-12^\circ$ C., which, however, could not be further identified because of the limited quantity of material. Obviously, this is a new adulterant, the nature of which will be determined when larger quantities of material are available.—Chem. and Drugg., Febr. 19, 1910, 293.

French Oil of Peppermint—Constituents.—In continuation of their investigations of French peppermint oil, Roure-Bertrand Fils were able, by fractional distillation of the oil after saponification, to identify the following constituents: 1. Isovaleric aldehyde. 2. Isoamylic alcohol. 3. l-Pinen. 4. $\Delta^2$-p-Menthene (?). 5. Cineol. These constituents amount to about 6 per cent. of the oil examined. Analysis also showed the oil to contain 38 per cent. of free and 13.5 per cent. of esterified menthol, as well as 6.4 per cent. of menthone. Further details as to the investigation, which are still proceeding, are promised.—Schimmel’s Semi-An. Rep., October, 1909, 98; from Rep. of Roure-Bertrand Fils, April, 1909, 76.

Oil of Petit-grain—Constants.—Roure-Bertrand Fils have determined the constants in a sample of oil of petit-grain received from Mr. R. Plaideau, of Anjouan, Comoro Islands, which they report as follows: Sp. gr. at $15^\circ$ C., 0.8650; opt. rotation, $+42^\circ$, 18'; soluble in all proportions in 90 per cent. alcohol; insoluble in 80 per cent. alcohol; coefficient of saponification, 33.6; esters, calculated as linalyl acetate, 11.7 per cent.—Rep. of Roure-Bertrand Fils, October, 1909, 42.

West Indian Petitgrain Oil—Properties.—Schimmel & Co. report the following properties of a specimen of petitgrain oil of West Indian origin, distilled from leaves, which had been placed at their disposal by the Imperial Institute in London: $d_{15^\circ}$ 0.8531, $a_D + 43^\circ$ 36', acid number 1.2, ester number 6.1, soluble in 4 to 5 volumes of 90 per cent. alcohol, with slight cloudiness. These constants differ from those of the commercial oil, and besides, the odor also showed a difference, so that the oil appeared to be unsuitable for perfumery purposes.—Shimmel’s Semi-An. Rep., April, 1910, 90.

Petitgrain Oil—Adulteration.—Ernest J. Parry has recently examined a number of South American petitgrain oils which proved to be adulterated with artificial esters not hitherto observed; but the reactions, in so far as they could be obtained with the limited material, pointed to the presence of tartaric acid, and it therefore seems probable that the adulterant in
question was an ethyl tartrate—probably diethyl tartrate. Two other oils, more clumsily adulterated, contained 10 and 15 per cent. respectively of oleic acid in a free state.—Chem. & Drugg., Sept. 4, 1909, 410.

Oil of Pimenta Acris Fruits—Properties.—Although the essential oil of the leaves of Pimenta acris is well-known as a perfume for bay rum and similar toilet articles, under the name of "West Indian bay oil" or "oil of Myrcia acris," and is distilled in considerable quantity in the West Indies, the essential oil of the fruits does not appear hitherto to have been prepared. Consequently, interest attaches to a recent trial distillation, at the instance of the Imperial Institute, of a parcel of the fruits from Mauritius, which yielded 3.3 per cent. of oil closely resembling the leaf oil in its properties, and having the following characters: Sp. gr. 0.9893 at 15° C.; \( a_n = 1^\circ 20' \); solubility, 1:08 and more of alcohol, 80 per cent.; eugenol, 70 per cent.—Pharm. Journ. and Pharmacist, June 11, 1910, 727; from Bull. Imp. Inst., 1910, 8, 4.

Oil of Rhus Cotinus—Properties.—Perrier and Fouchet have distilled from the young twigs of Rhus Cotinus L., known in commerce as "Zante fustic," a colorless volatile oil, obtaining a yield of 0.1 per cent. The oil had a faint odor of turpentine and gave the following constants: \( d_{50}^{\circ} 0.875 \), \( a_n + 13^\circ n_b 1.4693 \), acid no. 6.1, sap. no. 34.3; soluble in 70 parts of 80 per cent., 10 parts of 85 per cent., and 3 parts of 90 per cent. alcohol; miscible in any proportions with 94 per cent. alcohol.—Schimmel's Semi-An. Rep., April, 1910, 92; from Bull. Soc. Chim., iv, 5 (1909), 1074.

Otto of Rose, 1909—Characters.—Having had the opportunity to examine samples of practically all the brands of the 1909 season’s otto of rose offered on the London market, John C. Umney records the results as regards odor and their physical and chemical characters in the following table, exhibiting them in accordance with his personal recognition of their odor value, checked by the opinions of an English and a French expert.

A comparison of these results with those obtained with five samples of pure otto of rose and three samples of impure oil, examined in 1896, point out that while there is an apparent rise in percentage of alcohols in the finest otto of rose, there is also an apparent adjustment of the congealing point of the impure oils to that of normal pure oils, as shown in the lower part of the present table. The three impure oils examined in 1896 had crystallizing points of 18.7° to 19.4° C.; the three unsatisfactory oils in the above table are shown to have the melting points 21°–22° C., thus corresponding in this respect with the oils considered pure. The author accounts for this by the fact that at the present time, owing to the manufacture of stearopteneless oil, large quantities of otto of rose stearoptene are now available, and that this stearoptene, together with specially prepared hydrocarbons, is used for the sophistication of the oil. From all these and other observations, he concludes that the adulteration of otto of rose is to-day generally of a much more skilful nature than it was ten years ago, and that physical and chemical characters alone do not guarantee the purity of a given sample. On the other hand, perfectly pure samples may have characters very slightly outside the average of a season's otto, but so long as the odor of such otto is of the best it should not be condemned, though, if the odor is not that of a typical pure otto, it should be unhesitatingly condemned, even if apparently perfect as regards physical and chemical constants.—Chem. and Drugg., Nov. 20, 1909, 786.

Otto of Rose—Adulterants.—Ernest J. Parry, the adulteration of oil of rose is being carried on at present to a great extent, and a great deal of scientific skill is being used to produce mixtures of geraniol and allied bodies with the same physical characters as the genuine oil. He therefore thinks that the determination of the amount of alcohols present in the oil, calculated as geraniol, is the most useful test to supplement the physical characters. Genuine otto of rose rarely contains as much as 75 per cent. of alcohols, calculated as geraniol, and any figure above this must be regarded as being suspicious. Five samples of otto of this season's distillation, all of which were sold as "guaranteed pure," have all been found to be adulterated, giving the following figures on analysis:

Samphire Oil—a Prospective Source of Dill-ApioI.—F. Borde has distilled an essential oil from samphire (Crithmum maritinum, L.), which bids fair to assume some importance as a cheap and rich raw material for
the preparation of dill-apiol, hitherto difficult to obtain, since it contains about 40 to 60 per cent. of this body. The oil in question was distilled from the plant gathered almost at the end of the flowering season. The plant contained 80 per cent. of water. The oil-yield was as follows: Of plants collected in the first half of August, leaves and stems gave 0.3 per cent., fruit, 0.7 per cent.; in the second half of August 0.15 and 0.8 per cent., and in the middle of September 0.154 and 0.7 per cent. respectively. The oil from the leaves and stalks is specifically heavier than that from the fruit; it has a deep yellow color, and an aromatic, somewhat pungent odor of the plant. The crushed fruits, however, yield a pale yellow oil, which has a pleasant odor, especially when the fruit has been air-dried. The subjoined table gives the properties of the oil from the various parts of the plant, "A" being oil from leaves and stems "B" from fruit.

In addition to the above data, the b. p. (170 to 300° C.) and the solubility in alcohol (1:6 of 90 per cent. alcohol) of the oil distilled from ripe and dried fruit are recorded. In the fractions boiling over 200° C., which were examined more closely by Delépine, the presence of dill apiol (40 to 60 per cent.) was determined, and positively identified by preparing the tribromo-compound (C<sub>15</sub>H<sub>13</sub>BrO<sub>3</sub>Br<sub>3</sub>; m. p. 110° C.), and also by converting the dill apiol into dill iso-apiol, m. p. 44° C.—Schimmel's Semi-An. Rep., October 1909, 108-109; from Bull. des Science Pharmaco- col., 16 (1909), 132 and Compt. rend., 149 (1909), 215.

From a reprint of Mr. Borde's paper, received by Schimmel & Co, the additional information becomes available that the fractions of samphire oil with low b. p. contain a terpene, b. p. 158 to 160° C., d<sub>10</sub> 0.8703, [α]<sub>D</sub> + 44° C. 37' (very probably d-pinene), as well as another terpene boiling between 176 and 180° C. (d<sub>10</sub> 0.8957, α<sub>D</sub> ± 0) which has not been more closely identified.—Ibid., April, 1910, 94.
Sandalwood Oil—Constants of 200 Distillates from Mysore Wood.—C. A. Hill and J. C. Umney have suggested the following constants for the monograph on sandalwood oil for the next B. P.: Specific gravity at 15.5° C., 0.973 to 0.985; optical rotation (100 Mm. tube) at 20° C., —16° to 20° C.; solubility in 70 per cent. alcohol at 20° C., 1 vol. in 6 vols. These figures are evidently based on data taken from recent laboratory records of Messrs. Stafford Allen & Sons, representing about 200 distillates from Mysore sandalwood obtained by them during a period of two years and nine months, which are given in detail in the present paper.—Chem. & Drugg., Febr. 19, 1910, 293.

Oil of Storax—Gross Adulteration.—Schimmel & Co. call attention to two storax oils, offered as “guaranteed pure,” but below the market price, which on examination proved to be grossly adulterated. The first sample gave the following constants: 1. d_{150} 1.0986, a_d —1° 55', acid no. 0.5, ester no. 239.9, n_{D30} 1.56149; soluble in twice its vol. of 80 per cent. alcohol with slight opalescence. A detailed examination showed that the oil was simply benzyl benzoate scented with styrene, for when subjected to distillation under 4 Mm. press., they obtained between 35° and 40° C., about 5 per cent. first runnings possessing the characteristic odor of styrene, while about 90 per cent. of the total oil passed over almost uniformly at 156° to 157° C., and possessed all the constants of benzyl benzoate: d_{15} 1.1246, n_{D20} 1.57000, sol. p. +18.1°, ester no. 262.3.

The second sample had the following constants: d_{D15} 0.8781, a_d +19° 20', acid no. 0.1, ester no. 5.0, n_{D15} 1.47760; soluble in 5 to 6 vols. of 90 per cent. alcohol, forming a slightly cloudy solution. This differed from the first in its very low sp. gr., its refractive index also was too low, its optical rotation, on the other hand, much too high. The suspicion which was naturally aroused that in this case also the oil was adulterated, was confirmed by its behavior on boiling. By subjecting the oil to distillation a fraction amounting to 45 per cent. was obtained, which passed over under 757 Mm. at from 156° to 160° C., and which consisted of pinene (d_{15} 0.8668; a_d +21° 33'; n_{D20} 1.47225; m. p. of the pinene nitrobenzylamine 121.5° C.) As this hydrocarbon has not been met with in storax oils up to the present, and in any case cannot possibly occur in them to any large extent, it is quite certain from the values given above that the oil was adulterated with oil of turpentine to an almost incredible degree.—Schimmel’s Semi-An. Rep., April, 1910, 101.

Vetiver Oil—Possible Production in the Philippines.—According to Bacon vetiver or cuscus grass is found in the Philippine Islands, where its roots are known as moras or rais moras. A few sample distillations from roots grown in experimental plantations gave the following result: Yield of the fresh crushed root: 1.09 per cent. of a pale yellow oil. In order to separate the water better from the oil, which has almost the
same specific gravity, petroleum was added, which was afterwards distilled off in vacuo. The oil possessed a strong, agreeable odor, and had the following constants: $d_{15}^o 0.9935$, $a_{D30}^o + 32.1^o$ C., $n_{D20}^o 1.5212$, sap. no. 47.4. Green root, not previously crushed, yielded upon distillation 0.3 per cent. of oil, dried root, uncrushed, when extracted with ligroin, gave 0.25 per cent. of oil with a very faint vetiver odor. Dried root which had been kept in sacks for 3 months, when distilled continuously by steam, with cohobation of the water, gave 0.456 per cent. of a brown oil of powerful odor, possessing the following constants: $d_{15}^o 0.9964$, $a_{D30}^o + 32.1^o$ C., $n_{D20}^o 1.5163$, sap. no. 6.06. The experimental distillations were conducted with material varying in quantity from 65 to 175 lbs. The yield of root per acre is stated to be about 7200 lbs. The oil-content appears to increase up to the flowering time of the grass, and it would therefore probably be desirable to harvest and distil the roots when they are not more than three months old. The plants are propagated by dividing the roots; it has not been attempted to raise them from seed. The author succeeded in detecting the presence of several acids in the vetiver oil. 100 Gm. of the last described oil yielded 19 Gm. of acid mixture whose odor reminded of fatty acid, which in turn yielded on distillation in vacuo 40 per cent. of a pale yellow, viscous acid, boiling at 200°–205° C. at 4 Mm. The analytical figures of this acid and of its sodium salt gave the formula $C_{15}H_{24}O_2$. Another sample of vetiver oil yielded on saponification considerable quantities of benzoic acid.—Schimmel’s Semi-An. Rep., October, 1909, 126; from Philippine Journ. of Sc., 4 (1909), A, 118.

Oil of Wild Celery—Properties.—Schimmel & Co. describe an oil distilled in the south of France from the herb and seed of the wild celery (ACHE DES MARAIS). It was of a pale yellow color, had a pronounced odor of celery, and gave the following constants: $d_{15}^o 0.8713$; $a_{B} + 58^o$ 30'; $n_{D20}^o 1.47715$; acid number, 1.8; ester number, 41.5. No clear solutions could be obtained even with 95 per cent. alcohol, the reason of this being that the oil, which was distilled last year, had become considerably resinified in the meantime. After rectification with steam (in the course of which process a residue of 7.7 per cent. remained) its properties had undergone considerable change: $d_{15}^o 0.8541$; $a_{B} + 70^o$ 55'; $n_{D20}^o 1.47489$. Soluble in 6 vols. and more of 90 per-cent. alcohol with slight turbidity. —Schimmel’s Semi-An. Rep., October, 1909, 37.

Ylang-Ylang Oil—Classification of Grades and New Method of Extraction.—As the outcome of control tests made with 31 ylang-ylang oils of the first, and 22 of the second quality, Bacon confirms the classification of this oil on the basis of its constants, which he published last year (see Proceedings 1909, 333). The limits in the constants as now ascertained are as follows. First-grade oils: $d_{15}^o 0.910$ to 0.945 (mostly about 0.920 to 0.930), $a_{D30}^o—22^o$ to 50.8° C. (mostly —40° to 50° C.); $n_{D30}^o 1.4863$
to 1.4944; ester number, 92 to 129 (average 104); ester number after acetylation, 154 to 214 (average 182). Second-grade oils: \( d_{15}^{\circ} \) 0.905 to 0.925 (mostly about 0.910 to 0.915); \( d_{13}^{\circ} \) 38.5° to 79.3° C. (fluctuating very irregularly); \( n_{\text{B}}^{\circ} \) 1.4910 to 1.5030 (mostly keeping closely to the limit values); ester number, 71 to 88 (average 81); ester number after acetylation, 96 to 141 (average 118). The author also made experiments for obtaining ylang-ylang oil by extraction with volatile solvents, among which petroleum ether gave the best results. The yield was from 0.7 to 1.0 per cent. of an oil of very dark color, containing fairly large proportions of resin. Undiluted, the oil had neither a particularly agreeable, nor even a powerful odor, but when it was much diluted the perfume of the flower was clearly apparent. It had the following constants: \( d_{10}^{\circ} \) 0.940; \( n_{\text{B}}^{\circ} \) 1.4920; ester number, 135; ditto after acetylation, 208. It will be seen that these properties agree with those of first-grade distilled oils, and the slight difference in the odor of extracted oil as compared with the natural article is ascribed to the presence of small proportions of unknown compounds which are readily decomposed by heat. The extracted oil is also said to have this advantage that it cannot be imitated synthetically, and it is therefore possible that it may command much higher prices than distilled oil. When the extracted oil was shaken with water not inconsiderable quantities of resin separated out, which possessed the characteristic flower odor, while the residual oil assumed an odor of p cresol methyl ether.—Schimmel’s Semi-An. Rep., October, 1909, 130; from Philippine Journ. Sc., 4 (1909), A, 127.

**Ylang-Ylang Oil—Constants of a Sample from Nossi-Bé.**—Roure-Bertrand Fils report the results of examination of oil of ylang-ylang distilled in the island of Nossi-Bé and believed to be pure, as follows: Sp. gr. at 15° C, 0.9673; rotation, — 42° 12'; soluble in 1 vol. of 90 per cent. alcohol, with a slight violet fluorescence, later a cloudiness; acid value, 1.4; sapon. number, 129.5, sapon. number after acetylation, 154.7; esters (as linalyl acetate), 45.3 per cent.; total alcohols, 42.7 per cent.; combined alcohols, 35.6 per cent.; free alcohols, 7.1 per cent. These characters differ from those of previously examined oils from Manila and Réunion, and it is evidently inferior to those, although the inferiority may be due to the method of preparation.—Rep. of Roure-Bertrand Fils, October, 1909, 43.

**Oil of Zedoary Root—Constants of a Philippine Product.**—Bacon states that the plant yielding zedoary root oil, *Curcuma zedoaria*, Rosc., grows abundantly in the neighborhood of Manila. 100 kilos of the root of this shrub yielded 65 Gm. (0.065 per cent.) of oil, as well as 40 Gm. of a well crystallizing volatile solid body. The oil was deep bluish-green and possessed an agreeable odor faintly reminding of camphor. \( d_{10}^{\circ} \) 0.933; \( n_{\text{B}}^{\circ} \) 1.4920; probably inactive; in any case \( a_{1300} \) not exceeding +1.5°;
owing to the dark color an exact reading was impossible. It dissolved readily in 2 vols. and more of 8o per cent. alcohol. When the parts with the lowest b. p. were distilled in vacuo the camphor-like odor, which is probably due to the presence of cineol, was lost, and its place taken by a true flower-odor. A more thorough examination of the oil is to be made later on.—Schimmel's Semi-An. Rep., October, 1909, 131; from Philippine Journ., Sc. 4 (1909), A, 132.

ALCOHOLS AND DERIVATIVES.

Alcohol and Alcoholic Beverages in the U. S. P.—M. I. Wilbert discusses the question of retaining alcoholic beverages, such as brandy, whisky and wines in the U. S. P. and what restrictions, if any, should be placed on the sale of alcohol, concluding that brandy, whiskey and red wine at least should be deleted from the Pharmacopoea. This paper appears in the "Proceedings," 1909, 788–792.

Absolute Alcohol—Preparation.—W. H. Warren describes an apparatus which serves at once for boiling the alcohol to be dehydrated over the dehydrating agent, drawing off samples for determination of specific gravity during the treatment, returning them if the operation is incomplete, and distilling without first cooling when the satisfactory specific gravity is obtained. The results of experiments with the apparatus are summarized thus: (1) It is not possible to deprive commercial alcohol of all its water by boiling over lime. Dehydration takes place gradually up to a certain point, and it is useless to boil longer under return-condenser when the test-distillate contains 99.87 per cent. (2) Commercial alcohol can be brought to the point where it will give a test-distillate containing 99.87 per cent. by boiling six hours without previous standing over lime; or, by boiling five hours, after allowing the alcohol to stand for twenty-four hours over lime. (3) When the test-distillate contains 99.87 per cent., the alcohol, if distilled, will contain as a whole 99.94 per cent. The author has never succeeded in getting a distillate containing a higher percentage of alcohol than this. (4) It is possible to increase the yield of absolute alcohol by conducting the dehydration in two stages and using each time a quantity of lime only in slight excess of that theoretically required to combine with the water present. But the absolute alcohol obtained will by no means be as strong as it will be if dehydration takes place at one operation in presence of a large excess of lime.—Journ. Amer. Chem. Soc., May, 1910, 698.

Alcohol.—Rapid Determination.—D. Sidersky describes the following method for the rapid determination of alcohol, which depends on the miscibility of ether with strong alcohol: Twenty Cc. of the alcoholic liquid under examination and 10 Cc. of ether of sp. gr. 0.724, are shaken in a closed vessel; on standing, the liquids separate into two layers. Successive quantities of alcohol of 98° C. are now added from a special burette, the mixture being shaken between each addition. The ethereal-
alcoholic layer diminishes progressively, and addition of alcohol is continued until the last drop of alcohol added causes the complete disappearance of this layer. The burette employed in adding the alcohol is so graduated as to give the percentage of alcohol in the sample directly. The vessel in which the admixture is made has a very narrow neck, so that the separation of the two layers may be easily distinguished.—Pharm. Journ. and Pharmacist, Febr. 19, 1910, 205; from Bull. Chim. Sucr. et Drit., 27 (1909), 562.

The New Alcohol Tables of the U. S. Bureau of Standards are the subject of a paper by A. B. Lyons in which after pointing out the deficiencies of the several alcohol tables given in various Pharmacopoeias, he states that he has examined the five tables prepared by the Bureau of Standards, figure for figure, looking in vain for misprints or serious errors in computation, and regards them entitled to acceptance as authoritative. These tables are published with Mr. Lyons' paper in the "Proceedings," 1909, 907–918.

Ethyl Ether—Influence of Water and Alcohol on the Boiling Point.—Dr. John Wade and Horace Finnemore have experimentally studied the influence of water and alcohol on the boiling point of ethyl ether. The first part of their paper deals with the examination of ether purified by existing processes, in the course of which they discuss simple dessication with calcium chloride, lime, sodium, and phosphoric oxide. Then oxidation and dessication, and exhaustive washing and dessication are discussed. The results show that the boiling point of pure ether is very near 34.50° C., and its sp. gr. probably below 0.71994. The second part of the paper deals with the isolation of a binary mixture of ether and water, the investigation of a supposed binary mixture with alcohol, and the absence of a ternary mixture. The binary mixture with water boils with a remarkable constancy at 34.15°, or 0.35° C. lower than pure ether, and contains 1.38 per cent. of water, so that in the fractionating of moist ether this binary mixture commences to pass over before the pure ether, and, unless all but a trace of water is first removed, pure ether cannot be obtained from it by any process of distillation. Further, it is shown that the complete elimination of alcohol is also a necessary condition in purification. The authors find that absolutely pure ether is, like absolute chloroform, peculiarly unstable, and the investigation is being continued with a view to determining the best methods of purification.—Chem. & Drugg., Dec. 4, 1909, 862; from Journ. Chem. Soc., Nov., 1909.

Ether—Contamination with Vanillin.—Having occasion to examine a sample of ether which had proven unsatisfactory in its anesthetic action in six cases, K. Feist found the otherwise pure ether to contain appreciable quantities of vanillin. Speculating on the probable source of the contamination he considers it possible that the vanillin was derived from the cork stopper of the container.—Apoth. Ztg., xxv (1910), No. 13, 104.
Acetic Ether—Conditions Affecting its Production and Composition.—J. Habermann and H. Brezina have made some interesting studies concerning the conditions affecting the production and composition of acetic ether. It is usually assumed that the formation of this ether from alcohol acetic acid in the presence of sulphuric acid, as expressed by the equation 
\[ C_2H_5O + C_2H_4O_2 = C_2H_5O_2C_2H_5 + H_2O \] —is dependent on the action of sulphuric acid in removing and binding water from the reacting liquids. It therefore seemed plausible that the sulphuric acid might be replaced by some other dehydrating agent, and that this might lead to a new and more practical method for preparing acetic ether. For this purpose the authors selected anhydrous copper sulphate, mixing 160 Gm. of this with 400 Gm. of alcohol and 240 Gm. of glacial acetic acid, allowing this mixture to stand 24 hours, with frequent shaking, at the ordinary room temperature, and then subjecting it to distillation in a water-bath. After several rectifications a product was thus obtained, having the boiling-point 70°-72° C., which approximates closely to the boiling-point 72.78° C. given by Genther, while according to other authors acetic ether boils at 77.1°-77.5° C. These differences are explainable by the fact that commercial acetic ether is not a pure product. The authors have been able to confirm the observations previously made by Thomson that commercial acetic ether on repeated distillation over metallic sodium will yield a relatively small proportion of ether boiling at 70°-72° C. (which proved to be identical with the product obtained in large quantities from the mixture of copper sulphate, alcohol and glacial acetic acid) while the far greater portion had the constant boiling point 77° C. By a suitable method of distillation from calcium chloride the authors have succeeded in converting the lower boiling product (b. p. 70°-72° C.) obtained with copper sulphate, into pure acetic ether having the boiling-point 76°-77° C., and they conclude from this that the lower boiling fraction (70°-72° C.) is in reality a compound of 1 mol. of acetic ether with 1 mol. of ethyl alcohol.—Pharm. Ztg., liv (1909), No. 89, 879; from Journ. f. prakt. Chem., 1909, No. 20.

Ethylene Dichloride—A Useful Solvent for Iodine in Dermatology.—Dr. A. W. Wallace finds that ethylene dichloride is far preferable to alcohol or acetone as a solvent for iodine for sterilizing the skin, since the vapors the solution gives off are quite non-irritant. The vapors of acetone solution of iodine are very pungent and irritating, and where a large area has to be painted the atmosphere of the room becomes almost intolerable, and nurses and others are troubled with lachrymation and coryza, often of an intense kind. Of all the organic fat-solvents ethylene dichloride is found to give off the least irritant vapors; in fact, even the odor of iodine is barely perceptible. It it also quite as efficient as a fat solvent as the other organic liquids. Moreover, its vapors are non-inflammable. The following is the method of skin preparation pursued: (1) Immediately—a
few minutes to one hour—before operation, swabbing with a mixture of equal parts of methylated alcohol and ethylene dichloride. (2) Swabbing with pure dichloride. (3) Painting with iodine ethylene dichloride solution 2.48 per cent., known as "I.D.E." (4) Fixing sterile lint over prepared surface. The iodine stain formed on the skin is lighter than that produced by other solvents and disappears more quickly, without producing any irritation or dermatitis.—Pharm. Journ. and Pharmacist, June 25, 1910, 787; from Brit. Med. Journ., 1910, I, 1288.

Chloroformium Pro Narcosi—Proposed Tests of the G. P.—G. Arends enters a protest against the formaldehyde-sulphuric acid test, proposed for the new official "chloroform for narcosis" to be admitted into the forthcoming German Pharmacopœia, whereby the presence of traces of isomalol and chlorbenzol may be detected. He regards the sulphuric acid test, which has been made more severe by demanding that concentrated sulphuric acid shall not be affected by contact with an equal volume of the chloroform during 48 hours, instead of one hour now demanded for chloroform, as answering every purpose, since chloroform that will respond favorably to this test cannot contain the impurities looked for by the formaldehyde-sulphuric acid test. Moreover, he regards the value of the latter test as being problematic, since too little is known about its reactions with other bodies, while more important tests, such as that for phosgen, which have been proposed for better reasons, are ignored in the forthcoming revision.—Pharm. Ztg., lv (1910), No. 35, 355.

Chloroform—Its Purity when Prepared from Acetone the Cause of Irregularities in Narcosis.—It has been pointed out by J. Regnault that chloroform prepared from acetone is more liable to produce irregularities in its anesthetic effect than chloroform prepared from ethyl alcohol, even though the two are apparently identical when subjected to the usual tests. Careful investigation undertaken by Wade have now demonstrated, contrary to all expectations, that of the two kinds of chloroform, that prepared from acetone was the purest; it contained only the added alcohol and traces of water, while chloroform prepared from alcohol contained besides these also 0.05 per cent. of ethyl chloride. The greater regularity in the action of the latter is attributable to the presence of ethyl chloride. It has been found that the addition of ethyl chloride in the quantity mentioned, renders the acetone chloroform equally effective, while an increase to 0.25 per cent. ethyl chloride renders it superior to alcohol chloroform. —Pharm. Ztg., lv (1909), No. 68, 662; from Ztschr. Oester. Ap.-Verein.

Salol-Chloroform—Preparation and Use in Wound Treatment.—Bourlier highly recommends "Salol-chloroform," obtained by mixing equal volumes of salol and chloroform, for the treatment of infections, wounds and the sterilization of Laminaria pencils. On dropping about 30 drops of the syrupy liquid upon the wound, the chloroform rapidly evaporates
and leaves the wound covered with fine, dusty salol, which produces complete asepsis. Laminaria pencils, which had been made antiseptic by immersing into salol-chloroform, gave no evidence of even traces of bacterial growth after exposure during four days to bouillon cultures. Its freedom from odor and powerful disinfectant action leads the author to prefer it to iodoform ether.—Pharm., Zentralh. 51, (1910), No. 9, 173.

Iodoform — Classification of its Compounds Recommended as Substitutes.—Dr. George Cohn in an exhaustive paper briefly reviews the many iodoform addition compounds which have been proposed as substitutes, classifying them under four principal divisions, viz., Compounds of Iodoform: (1) With bases such as ammonia, trimethylamine, hexamethylene tetramine, etc.; (2) with sulphur compounds—such as sulphur, iodethylisulphide, triethylsulphonium iodide, etc.; (3) with sulphur and nitrogen compounds—exemplified by carbothialdin; and, (4) with albumin bodies, which, however, are probably not addition compounds, but merely mechanical admixtures in which the albumin simply modifies the odor and increases the volume of the preparation. None of these compounds appear to have satisfactorily served the purpose for which they were introduced; the correction of odor has been incomplete at best, or the undesirable odor is developed when the compounds come in contact with the wound exudation, by which they are split up into their components. Nevertheless, he considers it possible that by continued study, addition products of iodoform may be developed that will unite the therapeutic efficiency of iodoform with a stability that overcomes the objectionable odor, or that are in themselves of pronounced therapeutic value, and he has therefore reviewed the conditions under which the different compounds now proposed and supplied as substitutes of iodoform are produced, and their principal character, in the hope that he may thus encourage and assist in the further study of these interesting addition compounds.—Pharm. Zentralh., 51 (1910), No. 8, 145–50.

Iodoform—Estimation in Gauzes.—V. Paolini recommends the following method for the estimation of iodoform in gauzes: 10 Gm. of the gauze, cut into small pieces, is heated under a reflux condenser for 2 or 3 hours in an Erlemeyer flask of 500 Cc. capacity with 40 Gm. powdered zinc and 60 Cc. of 25 per cent. sulphuric acid. Then 40–50 Cc. more of sulphuric acid are added and the heating (on a sand or water-bath) is continued several hours longer. The iodine is then completely converted into hydrogen iodide, as evidenced by the complete decoloration of the gauze. The liquid is drained off, the gauze washed with repeated quantities of water, and the whole brought to the volume of 1 liter. Of this liquid, 100 Cc. are then shaken out with carbon disulphide after the addition of potassium nitrite and the liberated iodine dissolved by the CS₂ is estimated by means of sodium thiosulphate in the well-known manner, the
quantity of iodoform in the sample being calculated from that of the iodine so ascertained.—Pharm. Ztg., lv (1909), No. 97, 957; from Monit. scientif., 1909.

Chloral.—The condensation of chloral with primary aromatic amines is described in a paper presented to the Association by Alvin S. Wheeler and S. Jordan, of the University of North Carolina, which is a continuation of work previously described by Mr. Wheeler in the Journ. of the Amer. Chem. Society. The present paper appears in the “Proceedings,” 1909, 902.

Chloraloses—Definite Compounds of Chloral with Sugars.—Chloral forms a series of definite crystalline compounds with the sugars, which have been studied for some years by Hanriot. Of these the

Glucocloraloses may be taken as types; they are obtained by heating together on the water-bath 1000 Gm. of anhydrous glucose and of anhydrous chloral with 5 Cc. of fuming hydrochloric acid. Reaction takes place at about 80° C. The product, a glassy soluble mass, does not appear to contain chloraloses; but on boiling it with water these compounds are formed. The excess of chloral is removed by boiling with water, evaporating and crystallizing. The mother liquor is again freely diluted with water, boiled, evaporated, and again allowed to crystallize. In this manner a-glucocloralose and para or β-glucocloralose are obtained. The former C₆H₁₀O₆Cl₂, forms large needles from alcohol, melting at 187° C.; the latter, with the same formula, occurs in scales or prisms, melting at 227° C. Compounds and products of both are described.

Mannochloralose, C₆H₁₁O₆Cl₂, form small soluble scales, melting at 208° C.

Lavulochloralose is also discussed by the author and its structural formula shown. Sorbose and rhamnose do not form chloral compounds. Arabinose forms with bromal crystalline arabinobromalose, C₆H₁₀O₆Br₂, melting at 210° C.—Pharm. Journ. and Pharmacist, April 9, 1910, 455; from Compt. rend., 150 (1910), 623.

Methyl Alcohol—Question of Toxicity.—G. Arends, after reviewing the question of the toxicity of methyl alcohol, expresses the belief that the recorded observations are not based on the effects produced by pure methyl alcohol, but upon the toxic effects following the consumption of the impure alcohol or crude wood spirit used for denaturing ethyl alcohol. He therefore recommends that further investigations be made with pure methyl alcohol before condemning it for making certain pharmaceutical preparations and products.—Pharm. Ztg., lv (1910), No. 48, 489-490.

Formaldehyde—Alleged Production by Boiling Solutions of Cane-sugar.—A widely quoted statement made by A. A. Ramsay about a year ago to the effect that when solutions of cane-sugar are boiled at 100° to 103° C.,
as would be the case in making jellies, etc., formaldehyde is produced in appreciable amounts, has led Charles H. LaWall to study the subject experimentally. The results of these experiments, which are described in some detail, make it obvious that cane-sugar solutions do not develop formaldehyde when boiled under ordinary conditions, but that “furfuraldehyde” is produced, which reacts in such a manner with the Hehner test—the only one employed by Ramsay—as to deceive the analyst who relies on it alone, without confirmation by the Rimini test.—Amer. Journ. Pharm., August, 1909, 394–396.

**Formaldehyde—Photochemical Formation in Green Plants.**—S. B. Schryver contributes the results of some interesting researches on the photochemical formation of formaldehyde in green plants, which lead to a hypothesis contradicting in some directions the original conception of Baeyer. Employing a method for the determination of free as well as combined formaldehyde, available in dilutions of 1:1000000, which is described, the author found formaldehyde present in most specimens of chlorophyll examined, proving that the aldehyde exists in chlorophyll in fairly stable combination. Experiments made with chlorophyll films (obtained by evaporation of ether—solution of chlorophyll on glass strips) demonstrate that formaldehyde is formed in the sunlight, both in the presence and absence of CO₂, but in the last case in very small quantity; while in the dark no formaldehyde is formed. It appears probable that in sunlight and the presence of CO₂ a continuous synthesis of formaldehyde takes place resulting in the constant condensation of the latter into sugars, preventing the accumulation of toxic quantities of formaldehyde.—Pharm. Ztg., lv (1910), No. 39, 397; from Proc. Royal Soc. London, 82, 226-232.

**Formaldehyde—Production by Oxidation of Ethyl-Alcohol.**—By the aid of an extremely delicate reaction which is produced only in the presence of formaldehyde and permits the recognition of the latter in dilutions of 1:1000000, M. E. Voisinet has been able to detect the presence of traces of formaldehyde in pure ethyl alcohol after having subjected it to oxidation by chemical, physical or biological methods. The reaction consists in the formation of a violet color on treating an albuminoid substance with sulphuric or hydrochloric acid, containing a trace of nitric acid, in the presence of a trace of formaldehyde. The author's experiments justify him in assuming the presence of formaldehyde to be due to a secondary reaction occurring during the oxidation of the ethyl alcohol, and not to the accidental presence of methyl alcohol in the different ethyl alcohols used in the experiment.—Pharm. Ztg., lv (1910), No. 38, 386; from L'Union pharm., 1910, No. 4.

**Formaldehyde—Testing by the Pharmaceutical Chemist.**—Prof. Geo. D. Beal contributes a valuable paper on formaldehyde testing by the pharmaceutical chemist, in which he calls attention to the fact that while there are
Numerous and well-marked reactions for formaldehyde with other substances, not all are characteristic of this one aldehyde. The tests for formaldehyde, he says, may be divided into two groups, the one depending on oxidation, the other on condensation reactions—the latter again being subdivided into condensation with hydrazines, amines, phenols, etc. The author explains certain necessary precautions and reviews various tests that may be employed with satisfaction. He concludes that the oxidation reactions are the most reliable, and are best carried out in presence of milk, as the reaction partly depends upon the casein present. They are as delicate as the condensation reactions, and fewer bodies interfere. — Proc. Ohio State Pharm. Assoc., 1909, 41-44.

**Formaldehyde—Estimation.**—The “Chemiker Zeitung,” calling attention to the inadequacy of the usual methods for estimating the strength of formaldehyde solutions, proposes as a more reliable method that of Oscar Blank and Finkenbeiner (which depends upon the oxidation of the formaldehyde to formic acid with hydrogen dioxide in the presence of a measured quantity of normal soda solution and titration of the unconsumed alkali) and recommends that the process be conducted as follows: 3 Gm. of the formaldehyde solution are added to 25 Cc. of double normal solution of sodium hydroxide contained in a high Erlenmeyer flask; then, immediately, but gradually, 50 Cc. of pure hydrogen dioxide (2.5 to 3 per cent.) are added through a funnel, to prevent loss by spitting. After standing two or three minutes, the funnel is rinsed well with water and the unconsumed v.s. of sodium hydroxide is titrated back with double normal sulphuric acid, using litmus solution as indicator. With formaldehyde solutions of over 45 per cent., 30 Cc. of volumetric alkali must be used. In the case of solutions of less than 30 per cent. formaldehyde, the reaction should be allowed to go on for 10 minutes after the addition of the hydrogen dioxide. — Pharm. Ztg., liv (1909), No. 64, 624: from Chem. Ztg., 1909, No. 85.

**Formaldehyde—Colorimetric Method of Estimation.**—P. Dobriner and A. Oswald have devised a colorimetric method for the estimation of formaldehyde, which depends on the inverse application of the well-known reaction of morphine with formaldehyde-sulphuric acid—the formaldehyde vapor being passed into a solution of morphine in pure concentrated sulphuric acid and developing an intensely blue color which is visible with dilutions of formaldehyde of 1:250,000. The qualitative test is carried out by placing the substance or liquid under examination into a small dish, placing a small watch-glass containing the morphine-sulphuric acid solution over it, and covering the dish with another dish, inverted. The quantitative test depends on the time required for the reaction, the intensity of color, and comparison with known quantities of formaldehyde subjected simultaneously to the same test. — Pharm. Ztg., liv (1909), No. 65, 633; from Ztschr. f. anal. Chem., 1909, No. 9.
Formaldehyde—Determination in Presence of Acetaldehyde.—M. Deniges finds that formaldehyde may be detected in the presence of acetaldehyde by means of rosaniline bisulphite. If 5 Cc. of a solution of the latter (strength not given?) are added to a mixture of 5 Cc. of a 2 per cent. solution of acetaldehyde and 1-2 Cc. of sulphuric acid (sp. gr. 1.66), the mixture exhibits no particular change—at most a faint blue color, gradually diminishing. But if in place of acetaldehyde, formaldehyde or one of its mixtures be used, an intense violet coloration results, which is distinct even in the presence of $\frac{1}{10}$ Mgm. of formaldehyde in the fluid under examination. In this way the process of 0.01 per cent. of formaldehyde in acetaldehyde may easily be determined.—Pharm. Ztg., lv (1910), No. 38, 386; from Compt. rend., 1910, Febr. 28.

Formaldehyde—Determination in Formaldehyde Pastilles.—Domenico Cirelli recommends a method of determining the formaldehyde in formaldehyde pastilles, which depends on the depolymerization of the triformaldehyde contained in them by warming and conversion of the formaldehyde into hexamethylentetramine by means of ammonia. The depolymerization results if 0.2-04 Gm. of the triformaldehyde are heated in a tubulated retort in the presence of a little water. The liberated formaldehyde is passed successively through a flask containing 8 Cc. of ammonia, a Péligot-tube containing 2 Cc. of ammonia, and another containing 2 Cc. of hydrochloric acid, water vapor being conducted through the apparatus for half an hour after the volatilization of the triformaldehyde. The contents of the three receivers are then mixed, 8 Cc. of diluted HCl are added, and titrated.—Pharm. Ztg., lv (1910), No. 28, 283: from N. Chem. Zentralbl., 1910, No. 9.

Formaldehyde—Determination in its Saponaceous Compounds.—O. Allemann after comparative experiments with different methods for the determination of formaldehyde, recommends the following as being best adapted for its determination in its saponaceous compounds, such as lysoform, formosapol, and morbizid: 50 Cc. of the solution are diluted with 4 to 5 times the volume of water (in the case of "morbizid" with 20 times the volume), and the precipitant (sulphuric acid or barium chloride) is added from a burette in slight excess. The liquid is then diluted with water to 300 Cc., the precipitate allowed to subside, the liquid filtered, and the filtrate titrated directly for formaldehyde by the iodometric method. For this purpose, 5 Cc. of the solution are mixed with 40 Cc. of $\frac{1}{10}$ iodine solution, strong NaOH solution is added, drop by drop, until the color turns to light yellow, and the mixture is set aside for 10 minutes. It is then acidulated with H$_2$SO$_4$ or HCl, and the unconsumed iodine titrated with $\frac{1}{10}$ thiosulphate solution. Pharm. Ztg., lv (1910), No. 28, 283; from Ztschr. f. anal. Chem., 1910, 265-269.

Amyl Alcohol—Detection in Alcoholic Beverages.—H. Holländer recom-
mends the following method for the detection of amyl alcohol in alcoholic beverages: Twenty-five Cc. of the beverage to be tested are treated with 1 Cc. of normal potash solution, and placed in a distillation flask. After distilling the whole of the liquid, 5 Cc. of the distillate is mixed with an equal quantity of concentrated acetic acid, and the mixture boiled for about a minute. One drop of pure phenylhydrazine is added, the clear liquid again boiled, and then cooled in ice or running water, and allowed to rest at room temperature. On under-layering this solution with strong hydrochloric acid, there occurs a distinct green or emerald-green ring. Above this ring there sometimes occurs a brown coloration, but this is of no importance.—Pharm. Journ. and Pharmacist, May 21, 1910, 645; from Münch. Med. Wschr., 1910, 83.

**Amyl Alcohol—Color-Reaction with a-Naphthol.**—In the course of a study of the color-reaction of ordinary urine with solutions of a-naphthol, H. v. Wyss, E. Herzfeld and O. Rewidzow found that the same reagent applied to pure amyl alcohol in the same way produced an intensely blue violet coloration—4 drops of the reagent being added to 2 Cc. of the pure amyl alcohol, and three differently prepared reagents used—viz.: (1) 4.5 Gm. a-naphthol in 100 Cc. absolute alcohol and Na₂CO₃; (2) 4.5 Gm. in 100 Cc. of water and H₂O₂; (3) a 3 per cent. solution of a-naphthol. The second reagent, containing H₂O₂, is excluded. The reaction occurs quite as well when air is excluded. With isobutyl alcohol the reaction is only one-fourth as strong and it is still less with ethyl and cetyl alcohol, with glycerin and wax; while methyl and propyl alcohol, cane sugar, inosite, methyl acetate, acetic ether, acetone, benzol, petroleum ether, toluol, xylol, chloroform, fatty acids and uric acid give no reaction at all.—Pharm. Ztg., 1v., (1910), No. 38, 387; from Ztschr. f. physiol. Chem., 64, 479-480.

**Azomethane—Formation and Characters.**—J. Thiele describes azomethane, CH₃N₂CH₃, which he obtained by oxidation of hydrozomethane with potassium chromate. Azomethane is a colorless, non-alkaline gas, boiling point 1.5° C., having a faint yellowish color when liquefied, and congealing at below—73° C. to form colorless leaflets. It is readily soluble in water. If decomposed by heat, after previously diluting the gas with carbon dioxide so as to avoid explosion, azomethane splits up essentially into nitrogen and ethane, only small quantities of ethylene and methane being formed, probably according to the following equations: CH₃N₂. CH₄ = N₂ + 2CH₃; 2CH₃ = C₂H₆; 2CH₃ = CH₄ + CH₂; and 2CH₄ = C₂H₄. If, however, the azomethane is exploded by the electric spark, the formation of ethane is very materially reduced—hydrogen, ethylene and methane being formed abundantly instead. Acetylene could not be observed.—Apoth. Ztg., xxiv (1909), No. 58, 530; from Ber. d. D. Chem. Ges., 42 (1909), 2575.
Phenol—Cause of Red Color.—Gehe & Co. mention that according to recent investigation the red coloration of carbolic acid is due to the oxidation of minute quantities of the phenol into quinone, which dissolves in the phenol with a red color. Other products of oxidation of pure phenol are said to be pyrocatechin and phenoquinone.—Pharm. Ztg., lv (1910); No. 32, 325.

Liquefied Phenol—Use of Alcohol Instead of Water.—"H. R." suggests the liquefaction of phenol by means of alcohol instead of water. So prepared, it never freezes, is not liable to turn red, and is well adapted for oily dilutions and mixtures with volatile oils. The alcohol (1:5) in no way interferes with its use in wound treatment, since for this purpose it is always strongly diluted with water.—Pharm. Ztg., lv (1910), No. 21, 213.

Phenyl Salicylate—Liquefaction of Mixtures with Other Substances.—R. J. Wotring has made a study of liquefaction of mixtures of salol with other substances, with results as follows:

With Menthol: 1 mol. salol to 3 mol. menthol, or 3 mol. salol to 2 mol. menthol, produce dry powders on admixture; but 2 mol. salol to 3 mol. menthol produces a damp powder, and equal molecules of each a liquid.

With Camphor: In different proportions salol and camphor produce either pasty masses or liquids.

With Phenacetin, Antipyrine, or Salicylic Acid: These with salol alone produce dry powders, but the addition of a small amount of camphor to either mixture causes liquefaction.

With Thymol: 3 mol. salol to 1 mol. thymol, or 1 mol. salol to 3 mol. thymol, form pasty mixtures; in other proportions they liquefy.

With Chloral Hydrate: 1 or 3 mol. salol to 2 mol. chloral hydrate form moist powders; in other proportions dry mixtures result.

With Resorcinol: Dry powders result when salol and resorcinol are mixed in different proportions.

With Acetanilide: The same as with resorcinol, but addition of antipyrin to the mixture causes liquefaction.

With Beta Naphthol, Pyrogallol, or Sodium Salicylate: Dry mixtures result when either of these are mixed with salol.

With Antipyrine and Resorcinol: While dry mixtures with salol are obtained by either of these, if all three are mixed a pasty mass results.—Amer. Journ. Pharm., May, 1910, 241.

Guaiacolsulphonic Acid—New Salts.—A. Tagliarini has prepared and describes three new salts of guaiacolsulphonic acid, namely those of phenocoll, euquinine, and phenetidin.

Phenocoll Guaiacolsulphonate is obtained by mixing molecular quantities of phenocoll in ethereal solution and of guaiacolsulphonic acid in concentrated alcoholic solution. It forms a reddish-white powder, m. p. 183° C.,
sparingly soluble in water, soluble in alcohol, insoluble in ether. The aqueous solution is colored dark brown by chronic acid, brown by bromine water, blue-green by ferric chloride.

**Euquinine Guaiacolsulphonate** is obtained by double decomposition of basic euquinine sulphate with barium guaiacolsulphonate. The salt obtained has a dirty white color, a bitter taste and melts at 84° C., soluble in water and in alcohol; sparingly soluble in ether. Alkalies precipitate euquinine from its aqueous solution, which is colored blue-green by ferric chloride.

**Phenetidin Guaiacolsulphonate** is obtained by the admixture of molecular quantities of its components in ethereal solution, forming a flocculent reddish-grey precipitate melting at 186°-188° C. Its solubility is like that of the euquinine salt. The aqueous solution gives a blue-green color with ferric chloride, changing immediately to violet.—Pharm. Ztg., liv (1909), No. 73, 715; from Nouv. Remèdes 1909, No. 10.

**Cresotinic and Toluic Acids—Pharmacologic Distinctions.**—While cresotinic and toluic acids are nearly related to each other chemically, and both related to salicylic acid, Dr. R. May finds them to differ essentially in their pharmacological action.

*Cresotinic Acids* (ortho-, meta-, and para-) resemble salicylic acid in their action as antiferments, as bactericides, as antipyretics, and as specifics in acute rheumatism. Their toxic effect in animals is about the same, but ortho-cresotinic acid is more depressing to the circulation.

**Toluic Acid**, on the other hand, in spite of its close relation to the cresotinic acids and to salicylic acid, does not seem to have any antipyretic action, as a dose of 20 grains given in a case of phthisis pulmonalis did not affect the temperature. Moreover, it differs greatly from both the other acids in its action, which does not promise for the drug any therapeutic application.—Pharm. Journ. and Pharmacist, Sept. 25, 1909, 393; from Brit. Med. Journ., Sept. 18, 1909, 791.

**Benzidine—Paradiamino-diphenyl—Simplification of Use for the Detection of Blood.**—Walter finds that the use of H$_2$O$_2$ in the method ordinarily employed for the detection of blood by means of benzidine, may be avoided by using tablets containing 0.1 Gm. benzidine and 0.1 Gm. sodium perborate. In use, one of these tablets is dissolved in 10 Cc. of glacial acetic acid. A few drops of the reagent so prepared produce almost instantaneously a green-blue color on a spot containing blood, or when the blood is in solution, admixture of the same with an equal volume of the reagent will have the same result. The tablets are stable and form with the prescribed quantity of acid a light brownish solution, which is available for the recognition of blood in dilutions of 1:100000.—Pharm. Ztg., liv (1910), No. 43, 436; from Merck’s Annual Rep., April, 1910.
Resorcinol—Characteristic Reaction.—Voley-Boucher and J. Girard describe a characteristic reaction of resorcinol, which depends on the properties of its aqueous solution to develop a beautiful green fluorescence with copper sulphate and potassium cyanide. To a few cubic centimeters of the neutral or at most faintly acid resorcinol solution several drops of 10 per cent. copper sulphate solution are added, followed by the same quantity of 10 per cent. potassium cyanide, the mixture is shaken and diluted with water until the originally red color assumes a yellowish-red tint. This then is characterized by the green fluorescence, which is distinct in solutions containing as little as 0.1 Gm. of resorcinol in 1 liter. It is important to note, however, that if the resorcinol solution is added to the mixtures of copper sulphate and potassium cyanide, no fluorescence is developed.—Pharm. Ztg., liv (1909), No. 97, 957; from Journ. de Pharm. d'Anvers, 1909, No. 20.

Glycerin—Tests Suggested for the U. S. P.—Thomas M. Starkie, basing his criticism on experience over a great many years in the glycerin business, says that many of the tests set forth in the Pharmacopoeia are indefinite and unreliable, and allow of so much possibility of contention, particularly by some pedantic analyst, that any glycerin could be claimed as failing to meet the requirements of the Pharmacopoeia. The requirements should be such as will avoid any possibility of advantage to any dishonest refiner by reason of tests that permit of any controversy or contention as to the meaning thereof, such as taste and odor tests, for example, which should be eliminated. Giving in each case a description of carrying out the test, the author submits the following as covering all reasonable requirements for establishing the purity of glycerin: (1) Specific gravity, not less than 1.294 at 25° C. (= 95 per cent. glycerin). (2) Carbonaceous matter, including mineral and carbonized impurities, not to exceed 0.01 per cent. (3) Ash, including chlorides, not to exceed 0.007 per cent. (4) Chlorides, not to exceed 0.001 per cent., figured as NaCl. (5) Total acid equivalent, in terms of NaOH, not to exceed 0.02 per cent. (6) Arsenic (by the Gutzeit test), not to exceed 1 part in 100,000. (7) Silver nitrate test, to show limit of chlorides and impurities having reducing properties. Glycerin conforming to these tests, as described by the author, will, in his opinion, insure such purity as is necessary and desirable for either food or medicine.—Amer. Journ. Pharm., June, 1910, 253–256.

Glycerin—New Method for Identification.—Denigès describes a new method for determining the presence of glycerin, which depends upon its conversion into dioxyacetone by heating it with bromine water on the water-bath, and identification of the dioxyacetone by a series of reactions with a number of bodies, such as codeine, resorcinol, thymol and β-naphthol. These, dissolved in concentrated sulphuric acid, give characteristic color reactions with dioxyacetone, partly at the ordinary temperature and
partly by the aid of heat; among these and others, which are described by
the author, the reaction with codeine is the most suitable for very small
quantities of glycerin. It gives a beautiful greenish-blue with strong red
fluorescence.—Pharm. Ztg., liv (1909), No. 68, 662; from Compt. rend.,
148 (1909), 570.

FIXED OILS AND FATS.

Fixed Oils — Comparative Value of Different Halogen-Absorption
Methods.—John Stewart Remington and Harold Lancaster record the re-
results of a comparative examination of the value of various methods which
have been adopted for fixing the halogen absorption of oils and fats, in
which they have compared in particular the results obtained by the Wijs
and Hanus iodine method with those given by Hübl. and all of these in
turn with the bromine absorption method recently proposed by McLlheney.
They find that better results are obtained by the Wijs than by the Hanus
or Hübl methods, but that none of the iodine methods are so rapid as
the bromine process of McLlheney, which is practically instantaneous.
Moreover, a standard bromine solution is easily prepared, will not change
or deteriorate on keeping, and is inexpensive—conditions which point out
a preference to any of the iodine methods.—Trans. Brit. Pharm. Conf.
(Yearbook of Pharmacy), 1909, 337-343.

Fixed Oils—Origin of Odor.—According to Tsujimoto's researches
the peculiar odor of oils, apart from the presence of impurities, may be
due to free volatile fatty acids or to decomposition products of gly-
cerides. The odor is difficult to remove permanently, since free fatty
acids are formed even in the purest oils. Linseed and sesame oils pre-
pared from fresh seed and treated at 100° C. with 10 per cent. of Fuller's
earth, neutralized with alcoholic potash and washed with alcohol, are at
first practically odorless. After being exposed to diffused daylight for
several days they acquire a characteristic odor. The intensity of the odor
of an oil is almost proportional to its iodine value, and apparently depends
on the amount of non-saturated fatty acids present. These oils are also
those which are most readily oxidized. The odor of marine animal oils is
partly due to volatile bases. These oils also contain non-saturated fatty
acids of the series CₙHₙ₋₂O₂, notably clupanodonic acid, which has been
isolated from cod-liver oils. The glycerides of these acids are easily ox-
idized and form odorous bodies of aldehyde nature. It is noteworthy that
Hébert has found the glyceride of isanic acid in isano oil, which has a
fishy odor. Clupanodonic acid from Japanese cod-liver oil has a very
marked fishy smell, and the fatty acids remaining after its removal are
almost odorless. Marine animal oils cannot be rendered perfectly odor-
less as long as they contain these glycerides; these must be entirely re-
moved or transformed into odorless products by chemical means.—Pharm.
Journ. and Pharmacist, Sept. 11, 1909, 342; from Chem. Rev., Fett, Harz,
1909, 85, through Nouv. Remédes, 26 (1909), 348.
Transvaal Fixed Oils—Examination of Several Kinds.—E. M. Holmes notes the results obtained by an examination of a number of fixed oils from the Transvaal by C. T. Bennett, which included castor, linseed, ground nut, and sunflower seed oil, and are reported by J. C. Umney as follows: The oils were turbid and dirty when received, but were allowed to clarify by settling. The castor oil was dark in color, and would require bleaching unless used for cattle or for industrial purposes. They afforded the following constants:

Edible Oils—Detection of Oils Extracted by Carbon Disulphide.—M. Curson published the following method by which the adulteration of edible oils with oils extracted by carbon disulphide, although not of frequent occurrence, may be detected: About 200 Gm. of the oil to be tested is weighed into a flask along with 50 Gm. of 90 per-cent. alcohol; after vigorously shaking the mixture, the flask is attached to a condenser, and distillation conducted gently on a water-bath. The distillate is collected in a small receiver immersed in cold water and containing a few Cc. of alcohol in which a little potassium hydroxide is dissolved. The traces of carbon disulphide carried over in the distillate, form, with the alkali, potassium xanthate. The distillation is stopped when about one-third of the alcohol has distilled over. To the distillate is added, by drops, sufficient acetic acid to render the liquid just slightly acid, and then a few drops of an alcoholic solution of copper acetate. If potassium xanthate has been formed in the receiver, there is formed at first a yellow coloration and then, shortly afterwards, a precipitate of copper xanthate, of the same color. If the oil examined contains no adulteration of the kind referred to there is no coloration produced.—Pharm. Journ. and Pharmacist, Oct. 9, 1909, 451; from Annal. des Falsificat., Sept., 1909, 409.

Fats—Effect of Exposure to Cold.—H. Wagner and T. Bohrisch have studied the effect of cold upon fats, with particular consideration of the chemical changes possibly resulting from exposure to freezing temperatures. As a result of their studies they find that such exposure is practically without effect upon the chemical constants of fats, the changes oc-

Fixed Oils—Influence of Temperature on their Stability.—A series of experiments on the preservation of olive and almond oils at different temperatures and in different kinds of containers led L. E. Walbaum to the conclusion that in cold countries in which the temperature does not ordinarily exceed 20°–25° C., there is so little increase in the acid number, that these temperatures may be regarded as being without unfavorable influence upon them. Nevertheless, it is advisable to preserve them at the lowest practicable temperature, if possible in the ice-cellar. As to containers, it appears to be immaterial whether this is of glass or of tinned iron, but wooden containers should be avoided—possibly on account of the enclosure of air in the porous material. At temperatures of 37° to 58° C., the increase of acidity is very decided, the reaction at 58° C. probably occurring in three distinct phases, of which the second is the most pronounced and rapid.—Pharm. Ztg., liv (1909), No. 93, 919.

Fats—Practical Application of the Twitchell Process of Decomposition and the Recovery of Glycerin.—W. J. Warner gives a highly interesting account of the practical advantage of the Twitchell process of fat decomposition as applied to refining of glycerin and soap making, as carried out in a plant handling 50,000 lbs. of fat per day—a day, as he graphically explains, of 24 hours, without lunch hours, seven such days to the week, and 52 weeks to the year, one shift of employees relieving the other without any interruption of work from the beginning to the end of the year, and into the next. He says that the Twitchell process of distillation has superseded all others in the candle trade, and is being more extensively used by the soap manufacturers who have recognized the advantage of the process for the recovery of glycerin, in that 95 per cent. of all the glycerin in the fat can be obtained as C. P. This will give yield from: good tallow, 9 to 10 per cent. absolute glycerin; cocoanut oil, 12 to 13 per cent., cotton oil, 10 per cent. (approximate), grease and poor tallow, 6 to 8 per cent. absolute glycerin. The "sweet water" to be evaporated contains 15 per cent. glycerin instead of from 2 to 4 per cent. as in spent lye, and therefore only about 25 per cent. as much water has to be evaporated to make crude glycerin. The paper, which will well repay perusal—concludes with numerous analytical data obtained with different fats and oils, and of their products obtained by different processes.—Amer. Journ. Pharm., Febr., 1910, 71–80.

Expressed Oil of Black Mustard—Economic Value.—Schaumann breaks a lance for the fixed oil of black mustard seed, which is well suited for a variety of uses both pharmaceutically, as a food oil, and for technical purposes. It is susceptible of purification, so as to replace the
oils commonly used for food and as salad dressings, and in its purified condition, deprived of its objectionable color, it possesses certain advantages over the oils now official in the pharmacopoeia—taking up a much larger proportion of water, for example, and well replacing them in many of the preparations, such as rosewater ointment, medicinal soaps, spiritus saponatus, ol. hyoscyam. infus., etc., etc. In fact, on the ground of its superiority, he considers it desirable to admit mustard oil into the next German pharmacopoeia. Its purification is readily effected, so as to yield a colorless and practically tasteless oil, together with a lubricating oil as a by product. The chemical examination of the crude-, the purified-, and the lubricating oil yielded the following constants:

These figures apply to an oil expressed from seeds designated as "Sem. Sinapis Holland. Nigr."—Pharm. Ztg., lv (1910), No. 16, 160.

Borneo Tallow—Source and Uses.—According to C. Beadle and H. P. Stevens, borneo tallow, which may be obtained from the nuts of Shorea gysbertina, S. stenoptera, S. aperta, Hopea aspera, Isoptera borneensis, etc., is eminently adapted for candle making, soap making, and as an ordinary burning oil without smoke. The amount of oil obtained on pressing the nuts varies from about 40 to 60 per cent. Most of the borneo tallow exported from Sarawak appears to go to Antwerp, but ten times the amount now collected could be obtained by systematic treatment.—Chem. News, Oct. 8, 1909, 173.

Cacao Butter—A Skilfully Prepared Substitute.—W. B. Cowie and B. M. Brander have during the past year examined two cacao-butter substitutes, one of which was so skilfully prepared that it answered most of the tests for genuine cacao butter, whilst the other might have been rejected on any single test. The latter, which is designated as "soft," had a low acid and iodine value and abnormally high saponification and Reichert-Meissel values. But neither of them responded to the Björklund ether test for genuine cacao butter, the "hard" kind, having also a higher melting point (36°–37° C.) instead of the "hard," skilfully prepared substitute forming a flaky deposit when the ether solution was exposed for 3 minutes to 0° C., not clearing until 15° C., while the "soft" kind, though forming only a slight deposit at 0° C., was still cloudy at 21° C. The latter evidently consists of coco-nut stearin, but it is difficult to say what the chief components

Fish Oils—Detection in Vegetable Oils.—O. Eisenschimmel and H. N. Copthorne suggest the following test for fish oils of any kind in admixture with vegetable oils or similar products: 100 drops of the oil are dissolved in 3 Cc. of chloroform and 3 Cc. of glacial acetic acid. Bromine is added slowly drop by drop until the brown coloration remains, and after about ten minutes the test tubes are placed in boiling water. All vegetable oils clear up, while fish oils remain cloudy. By filtering and weighing the precipitate formed it is possible to obtain objective results. In case of boiled oils it is necessary to remove the metallic salts before adding the bromine. Fish oils that have been heated to 260° C. or more for some time will not respond to this test.—Pharm. Journ. and Pharmacist, May 14, 1910, 609; from Journ. Ind. and Engineer. Chem., ii, No. 2.

Goose Fat—Characters and Constants.—Having occasion to test some goose fat, Joseph L. Mayer was surprised at the paucity of information concerning the physical and chemical constants of this fat in the pharmaceutical literature. He has therefore made a determination of those in goose fat of his own rendering with results which, briefly stated, are as follows: Color, golden yellow; odor, characteristic; specific gravity, (100° C./15° C.), 0.8691; (40° C./15° C.), 0.8987; melting-point, 14.5° C.; refractive index, 40° C., 1.4594; free acids (as oleic), 0.209 per cent.; acid degree, 0.741; acid value, 0.413; iodine number (Hanus method), 72.66; saponification value, 191.0; saponification equivalent, 291.8; Reichert-Meissl number, 0.385: Hehner value, 94.43: Maumene number, 33.75; specific temperature reaction, 76.7; Valenta's test, 98° C. On adding 2 drops H₂SO₄ to 20 drops of fat, a greenish-yellow color is produced, changing to reddish-brown on stirring. Constants of the fatty acids are also given.—Drugg. Circ., March, 1910, 106.

Lard—Definitions.—Although the U. S. P. defines lard to be "the prepared internal fat of the abdomen of the hog (Sus scrofa, var. domesticus, Gray), purified by washing, melting, and straining," Azor Thurston says that "Leaf Lard," prepared from this leaf fat, is practically an article unknown in commerce. He says that under "Standard of Purity of Food Products" (Circ. No. 19, U. S. Dept. Agr.), lard, leaf lard, and neutral lard are defined as follows:

Lard is the rendered fresh fat from hogs in good health at the time of slaughter, is clean, free from rancidity, and contains, necessarily incorporated in the process of rendering, not more than one (1) per cent. of substances other than fatty acids and fat.

Leaf lard is lard rendered at moderately high temperatures from the internal fat of the abdomen of the hog, excluding that adherent to the intestines, and has an iodine number not greater than sixty (60).
Neutral lard is lard rendered at low temperatures.

As a matter of fact, what is sold as pure leaf lard is generally rendered from trimmings made in cutting the pork for packing and the fat adherent to the intestines, and is rendered either in closed steam tanks or open steam-jacketed kettles—the latter yielding the better, because drier, lard. Attention is called to the impurities which may be looked for and found in commercial lard, its adulteration and adulterants, and the tests considered to be generally sufficient to determine the purity of lard, which must be consulted in the original paper published in Merck's Rep., March, 1910, 64–65.

Ostrich Fat—Uses and Characters.—According to J. Vamvahas, the natives of Barbary prepare a fat from the ostrich, which they regard as a valuable remedy for rheumatism. Crushed ostrich bones and pieces of fat are boiled with water and the floating grease removed from the surface after cooling. The fat thus obtained separates on standing, at a temperature of about 28° C., into two distinct layers, the upper one liquid, the lower one solid. The liquid portion had the specific gravity 0.9255; critical temperature of solution in alcohol, 70° C.; Maumené index, 48° C.; melting-point, 8° C.; solidifying point, 2° C.; titer number, 49° C.; solidifying point of fatty acids, 35.5° C.; refraction index +23; Reichert-Meissl value, 7.6; Koettstorfer value, 211; Hehner value, 90.37; Huebl value, 71.12. The solid layer melted at 45° C., and solidified at 31° C. Its refraction index was +30.—Pharm. Journ. and Pharmacist, May 7, 1910, 571; from Annales Chem. Analyst., 15 (1910), 64.

Poppy-Seed Oil—Commercial Distinctions and Characters.—L. Vuafart says that, although at the International Congress at Geneva poppy-seed oil, "huile d'œillette," was defined as the oil of the seeds of the black poppy, this definition requires modification. Two varieties of poppy-seed oil are met with in European commerce, known as "œillette" and "pavot" oil respectively. Both are derived from seeds of varieties of *Papaver somniferum*. "Huile d'œillette" is obtained solely from poppies grown in Europe, with gray or blue seeds. It is more esteemed and has a higher commercial value than "pavot" oil, and is used extensively for dietetic purposes. "Huile de pavot," on the other hand, is derived from exotic poppy seeds, and has lower value. One of the chief points of distinction is the taste. "œillette" oil is sweet and nutty, "pavot" oil is stronger in flavor and somewhat acid. "œillette" oil is described as being "fatter" on the palate, giving the impression of greater viscosity, which is not, however, confirmed by the physical test. It forms a much more permanent froth on agitation than "pavot" oil, and on passing a current of air through the two oils "pavot" oil gives no froth, while "œillette" oil froths strongly. The latter, too, is bright yellow in color, the tint of "pavot" oil being only half this intensity. Ordinary physico-
chemical "constants" show no great difference between the two oils, the specific gravity of "œillette" oil, 0.926 to 0.924, being but very slightly greater than 0.923, the specific gravity of "pavot" oil. The flavor and frothing test serve to distinguish the two kinds of poppy-seed oil.—Pharm. Journ. and Pharmacist, July 17, 1909; from Annales des Falsificationes, 1909, 2, 276.

Phytosterins—Characters and Occurrence in Some Fixed Oils.—At the suggestion of Professor Schaer, Hermann Scherer has carried out some interesting experiments on the phytosterins and several fixed oils. He finds that the familiar reactions of the phytosterins are not applicable to their microchemical determination in the plant-cell. Both cholesterol and phytosterin are readily dissolved in solutions of chloral alcololate, but with much greater difficulty in chloral hydrate. Nevertheless, there exist differences of solubilities in the latter which may possibly serve as the basis of a method for their separation. The author finds in the unsaponifiable portion of the coffee-seed oil, consisting principally of an indifferent, brown, resin-like body, a phytosterin which must be regarded as being identical with Hess's phytosterin, and that the unsaponifiable fraction of Paranut oil, consisting principally of an amorphous yellow body, also contains the same phytosterin, and besides this an alcohol, n. p. 180° C., which cannot be regarded as being a member of the phytosterin group of bodies. Incidentally, it is mentioned that the fixed oils of fennel and anise are qualitatively identical, but exist in different quantities, while the fixed oil of caraway, in analogy to the volatile oils of these fruits, shows marked differences from those of fennel and anise.—Pharm. Ztg., liv (1909), No. 98, 969; from the author's inaugural dissertation, Strassburg, 1909.

Carbohydrates.

Viscose—Improved Method of Preparation.—F. Todtenhaupt states that the method of preparation of cellulose xanthogenate, better known as viscose, has remained practically the same since it was first introduced; it consists of treating cellulose with caustic alkali, whereby alkali-cellulose is obtained, and then submitting this to the action of carbon disulphide. The usual mode of procedure gives a good result with cellulose in short fibers, such as sulphite wood-pulp, but with long fibers like those of cotton wool, the difficulty of stirring thoroughly leads to particles of alkali-cellulose remaining unchanged, and it is somewhat troublesome and costly to remove these afterwards. It is now found that by diluting the carbon disulphide with a liquid which does not decompose either alkali-cellulose or viscose, the reaction proceeds to completion without the necessity of stirring. Benzin, ligroin, carbon tetrachloride, and similar liquids may be used, and by the choice of diluent and of degree of dilution the time required for the reaction may be made more or less, so that it is possible to stop it when only the outer layer of cellulose is converted, or to allow
the change to proceed to the end.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 671; from Chem. Ztg., Oct. 30, 1909, 1149.

Starch—Digestion by Infants.—The general conclusions of Dr. E. Cantley, derived from his observations, afford physiological and chemical support of the empirical use of starch in infant feeding and are briefly summed up as follows: 1. A diastasic ferment is secreted by the salivary glands and pancreas of new-born infants, and even before birth. 2. Its amount and activity are slight in the first few weeks of life and after that rapidly increase. 3. The glands, notably the pancreas, can be trained by means of a starchy diet to the secretion of an increased amount of the amylolytic ferment. There is no inherent reason why this training should not be begun shortly after birth in the case of the bottle-fed infants, instead of waiting until the child has attained the age of six months, as so commonly advised on purely theoretical grounds. 4. Practical experience has shown that the usual barley water contains about 2 per cent. of starch. If mixed with an equal quantity of milk there will be only 1 per cent. of starch in the mixture. Such an amount is non-injurious and almost certainly beneficial, for it encourages the growth of lactic acid bacilli and the formation of lactic acid. These organisms are of undoubted advantage, in the prevention of the growth of proteolytic bacteria. 5. If a starchy food is used in the first few weeks of life it is advisable to begin with a milk mixture which will not contain more than 0.5 per cent. of starch, and to gradually increase the amount as the child gets older. Indeed, at any age when a starchy food is first given it should be in a very weak solution and slowly strengthened up to as much as 3 to 5 per cent. If the stools become very acid, or they give a distinct starch reaction, the percentage of starch in the diet must be reduced. 6. Special care must be paid to these considerations in the first two months of life because of the deficiency of salivary secretion. Further investigations may possibly show that this is a point of little importance, as the pancreatic secretion may be sufficient in quantity and activity. 7. The evil effects of starch in early life are due to (a) excess; (b) its administration in the form of a more or less insoluble emulsion instead of as soluble starch; and (c) the substitution of starch for the necessary protein, fat, and salts. In other words, the mischief results from deficiency of necessary proximate principles of diet rather than from the presence of starch.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 701; from Lancet, Nov. 6, 1909, 1343.

Starch-Syrup—Detection in Honey and Fruit Juices.—Having observed that "honey-dextrin," from Conifere honey, is not precipitated by alcohol in the presence of hydrochloric acid, J. Fiehe applies this observation to a method for determining the adulteration of honey and fruit juices with starch-syrup, since "starch dextrin" is precipitated by alcohol under the conditions of the test. This is carried out as follows: Ten Gm. of the honey is heated with twice its weight of water on the water-bath.
One Cc. of a 5 per cent. solution of tannin is then added to precipitate albuminous matter. After standing for several hours the liquid is filtered. To 2 Cc. of the clear filtrate 2 drops of hydrochloric acid, sp. gr. 1.19, are added, and then 20 Cc. of alcohol, 94 per cent. If pure, the mixture will remain clear, but if starch glucose be present more or less turbidity will be apparent. In the case of fruit juices, 10 Gm. is treated with an equal weight of water and 8 drops of ammonium oxalate solution, and boiled. The turbid liquid is then treated with a little animal charcoal and filtered. The above test is then applied to 2 Cc. of the filtrate.—Pharm. Zentralh., 50 (1909), No. 43, 900; from Arb. a. d. Kais. Gesundh. Amt., 1909, 218.

Inulin—Quantities contained in Various Drugs.—Laine Rundqvist has determined the percentage of inulin contained in a number of roots and rhizomes, and reports the following results: Radix Artemisiae, 9.66 per cent.; R. Bardanæ, 46.25 per cent.; R. Carlinæ, 17.87 per cent.; R. Cichorii, 18.50 per cent.; R. Farfarae, 17.40 per cent.; R. Helenii, 35.10 per cent.; R. Pyrethri German., 26.19 per cent.; R. Pyrethri Roman., 35.66 per cent.; Rhizoma Arnicae, 5.55 per cent.—Pharm. Ztg., lv (1910), No. 4, 37; from Svensk Farm. Tidskr., 1909.

Sugars—Question of “Caramelization” by Rivas’ Test.—David Wilbur Horn contributes a paper in which he demonstrates experimentally that several phenomena accounted for by an assumption of caramelization may be accounted for by facts known to many chemists. Thus, the brown color of old syrup of ferrous iodide has been assumed to be due to caramelization, and several authors have more recently accounted for the yellow to brown colors produced on heating glucose with sodium hydroxide as, for example, in Rivas’ Test for B. Coli, to the same action. Conceding that by his experiments and illumination of the question, the last word has probably not been said, the author believes there is ample evidence that the assumption of “caramelization” in the case mentioned has no adequate experimental basis, and, not even probability, while the alcoholic and aldehydic characters of glucose may well account for the phenomena attributed to caramelization.—Amer. Journ. Pharm., April, 1900, 151-161.

Caramel—Saccharane a Definite Coloring Constituent.—F. Ehrlich finds that by heating, sugar, in vacuo, in an oil bath to 200° C., extracting the residue with boiling methyl alcohol until no more coloring matter is extracted, then redissolving the insoluble residue in water, filtering and evaporating to dryness in vacuo, an amorphous tasteless product is obtained, soluble in water, not precipitated by lead acetate, which is stated to have the definite chemical formula, C_{18}H_{22}O_{11}.2H_{2}O, and to possess an intense and constant tinctorial power. This has been named saccharane. It is proposed to employ saccharane as the standard for determining the color value of commercial caramels, expressing the degree of coloring power in terms of saccharane. Maltose, when similarly treated, gives a

New Crystallizable Polysaccharides—Production from Starch.—By the action of Bacillus macerans cultures on starch paste at 45° C. in presence of nutrient salts, F. Schardinger has obtained two crystallizable polysaccharides, acetone being formed at the same time. Neither of these polysaccharides reduce Fehling's solution, nor are they decomposed by yeast. The first of these, obtained from the aqueous product of reaction in the form of stout prismatic crystals, is designated by the author as

Crystallized Amylodextrin. This contains about 14.5 per cent. of water and, according to the variety of starch, shows an optical rotation of +136° to +138° (anhydrous = +158°). The mother liquors yield the second polysaccharide.

Crystallized Amylose, which crystallizes from alcohol in lancet-shaped needles, showing an optical rotation of +127.4°. The aqueous solution becomes yellow-brown with iodine, while that of amylodextrin becomes yellow, and on standing both deposit gray to green or blue crystalline needles.—Pharm. Centralh., 51 (1910), No. 3, 50; from Chem, Ztg., 1909, Rep. 50.

Galactose—Estimation.—The following method for estimating galactose is proposed by A. Fernace: 5 Gm. of galactose is placed in a tared beaker of 150 Cc. capacity, with 60 Cc. of nitric acid of specific gravity 1.150; the mixture is evaporated on a water-bath until the residue weighs 15 to 16 Gm. After cooling, 40 Cc. of water is added and the mixture set aside for twelve hours. The mucic acid which is precipitated is collected in a Gooch crucible, washed with 50 Cc. of water, and finally dried at about 100° C. until the weight is constant. Under these conditions, 100 parts of galactose equal 70 of mucic acid; a sample of galactose giving 70 per cent. of its weight of mucic acid is considered as sufficiently pure.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 701; from Ztschr. Physiol. Chem., 61 (1909), 284.

Dulcitol—A Sugary Secretion from the “Ghost Bug.”—D. Hooper states that Phromnia marginella, Olivier, the ghost bug, yields a white sugary secretion. The insect is found generally in northeast India. It affects various trees, such as Eleodendron glaucum, Pers., Grevillea robusta, etc. In Garhwal, the insects are called Dhaberi (sheep) on account of their habit of clustering together and jumping away when disturbed. They feed by sucking up the juices of the leaves, and the sugary matter is said to be excreted in a liquid state by the larva, and dropped onto the leaves, where it hardens and gives the bushes the appearance of having been frosted or whitewashed. This deposit is a manna-like sub-
stance of a pure white color. It occurs in grains of various sizes, or forms incrustations on and around the organs of the plant. It is sweet to the taste, and may be moulded like wax into balls. The solidified secretion is readily soluble in boiling water, from which it deposits, on cooling, hard, white, transparent crystals, which are neutral in reaction, inodorous, and slightly sweet, with melting-point 186° C. When burned they give off an odor of caramel, and leave no ash. They are soluble in about 12 parts of water at 28° C., and in 2½ parts of boiling water; scarcely soluble in alcohol, even on boiling. The solution does not reduce “Fehling” even after prolonged boiling with dilute acid. A combustion of the sugar afforded 39.3 per cent. of carbon, 7.7 per cent. of hydrogen, and 53 per cent. of oxygen, so that the body is dulcitol (dulcite), an isomeride of mannitol (mannite), C₆H₁₂O₆. The occurrence of dulcitol in the secretion of Phromnia marginella affords evidence as to the origin of certain mannlike incrustations on plants. The dulcitol in this case is deposited by the insect in an almost pure condition.—Pharm. Journ. and Pharmacist, June 25, 1910, 788; from Journ. and Proceed. Asiatic Soc. of Bengal, v (1909), No. 9, 363.

**Fucose—Properties.**—B. Tollens and F. Rovior have determined that fucose, C₆H₁₄O₆, exists to the extent of about 0.8 per cent. in dried seaweed. It does not undergo hydrolysis; it shows bi-rotation, and when oxidized by nitric acid gives dextrorotatory trioxyglutaric acid; the similar glutaric acid formed by rhamnose is laevorotatory.—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 81; from Berichte, 42 (1909) 2099.

**Stachyose—Occurrence in the Roots of Labiate Plants.**—L. Planet has determined the presence of stachyose by the aid of invertin in the subterranean parts of a number of labiate plants. The sugar was obtained in crystals and identified as stachyose by its optical properties before and after the action of invertin, by the melting point, and by the formation of mucic acid on oxidation with nitric acid. The following plants yielded this sugar: Lamium album, L., Stachys lanata, L., Stachys sylvatica, L., Stachys recta, L., Origanum vulgare, L., Mentha sylvestris, L., Bulbota foetida, L., Clinopodium vulgare, L., Salvia splendens, L., and Salvia pratense, L.—Pharm. Ztg., LV (1910), No. 48, 491; from Journ. de Pharm. et Chim., 1910, No. 5.

**Perseulose—A New Reducing Sugar.**—Gabriel Bertrand finds that oxidation of perseite by the bacteria of sorbose gives a new reducing sugar, perseulose, the formula of which is C₆H₁₀O₆. This sugar is a ketonic sugar. for it is not oxidized by bromine in aqueous solution, and, moreover, when hydrogenated by means of sodium amalgam and water it gives a mixture of two stereoisomeric alcohols, one of which is perseite, while the other, which has not been prepared previously, may be called perseulite. This result can only be explained on the assumption that perseulose contains
the CO group in its molecule. Its relation to per se is exactly the same as that of sorbose to sorbitäe, and it is thus the first representative of ketonic sugars with 7 atoms of carbon.—Chem. News, Oct. 8, 1909, 184; from Compt. rend., 149 (1909), No. 3.

Vicianose.—A Reducing Sugar from Vicia Angustifolia.—Gabriel Bertrand and G. Weissweiler, by the diastatic hydrolysis of the glucosite vicianin, obtained from the seeds of Vicia angustifolia, have isolated a new reducing biose to which they have given the name vicianose. It is very soluble in water, and only very slightly soluble in strong alcohol. Its rotatory power is given by \([a]_D = + 36°72'\). It fuses at 210° C. and elementary analysis shows that its formula is \(C_{11}H_{36}O_{10}\). Chem. News, March 4, 1910, 107; from Compt. rend., 150 (1910), No. 2.

ORGANIC ACIDS.

Glacial Acetic Acid—Commercial Quality.—Results of experiments recorded by Hermann C. T. Gardner indicate that glacial acetic acids of commerce can not conform to the B. P. standards of melting point nor absolute acid percentage (99 per cent.), and the author concludes that these discrepancies are doubtless attributable to the confusion caused by the anomalous statements of the official monograph, which should be corrected in the next edition of the B. P.—Pharm. Journ. and Pharmacist, July 17, 1909, 69.

Glacial Acetic Acid—Precaution in Determining the Strength by Titration.—P. A. W. Self recommends the following simple precaution to prevent loss of acetic acid during weighing and titration of glacial acetic acid. Into a tared bulb of thin glass furnished with a capillary opening (conveniently made by drawing out a narrow test-tube at an inch or so from its closed end) introduce a convenient quantity of the acid by the well-known expedient of warming the bulb and allowing to cool with the end of the capillary dipping below the surface of the acid. Then seal the capillary and weigh. Next place the bulb in a strong stoppered bottle containing an amount of standard alkali in excess of that required by the acid, stopper the bottle, break the bulb by vigorous shaking, and finally titrate the excess of alkali in the usual way. Obviously no danger whatever of loss by volatilization is possible, and the additional trouble is almost inappreciable.—Pharm. Journ. and Pharmacist, Dec. 11, 1909, 729.

Acetone—Iodometric Determination.—Ludwig Krauss has subjected the iodometric method of Messinger-Huppert which is usually employed for the determination of acetone in urine to critical experimentation, and following the directions of E. Späth ("Die chemische und mikroskopische Untersuchung des Harns," 3d Ed., 1908) in conducting the details, obtained results which proved to be absolutely unreliable. The method is carried out as follows: 50 Cc. of the aqueous acetone solution (or distillate
from the urine) are mixed with 30 Cc. \( \frac{N}{1} \) alkali and 25 Cc. \( \frac{N}{10} \) iodine solution, shaken one-half minute, then acidulated with 30 Cc. of 5 per-cent. HCl, and titrated with \( \frac{N}{10} \) thiosulphate. In this way the results are invariably too low. But if the mixture of acetone, alkali and iodine solution is frequently shaken during 15 minutes, before acidulation with HCl, the results are absolutely constant and uniformly reliable, not only for solutions of pure acetone, but also for the distillate from urine containing acetone.

**Acetone—Identification by Conversion into Acetylcarnbinol.**—C. Deniges observes that the reactions in general use for the identification of acetone are for the most part uncertain, and therefore proposes the following:

He first treats the acetone with bromine water, and then converts the bromacetone thus obtained into acetylcarnbinol by means of sodium carbonate. The method he adopts is to heat, for twenty minutes on a boiling water-bath, a mixture of 0.1 to 0.2 Cc. of acetone and 10 Cc. of 6 per cent. bromine water. The contents of the tube containing the mixture are then boiled until bromine vapors have completely disappeared and the liquid is colorless. The liquid (A) contains for the most part bromacetone and at the same time a little acetylcarnbinol. Five Cc. of the liquid, which gives off a very irritating odor, are treated with 0.5 Cc. of a ten per cent. sodium carbonate solution (and then gently boiled for a few moments to convert the bromacetone into acetylcarnbinol. This liquid B is allowed to cool, and 0.4 Cc. of it is treated with 0.1 Cc. of a four per cent. solution of potassium bromide and 2 Cc. of pure sulphuric acid (specific gravity, 1.84), in a test-tube. After shaking, 0.1 Cc. of a five per cent. alcoholic solution of salicylic acid is added, and the mixture again shaken. There is developed quickly, in the cold, an extremely intense violet or violet-red coloration. If a similar solution of guaiacol instead of salicylic acid be used under the same conditions an equally intense blue coloration is obtained, and that more quickly than the preceding. Under like conditions the liquid A gives similar tints, but much less intense than those of liquid B. The test may be applied to dilute solutions of acetone, and the reactions are regarded as specific for that body.—Pharm. Journ. and Pharmacist, Jan. 22, 1910; from Bull. Soc. de Pharm. de Bordeaux, Nov., 1909, 465.

**Benzoic Acid—Preparation from Toluol with Nitric Acid.**—Dr. Hans Sacchse has patented a new and economical process for the preparation of benzoic acid from toluol by the action of nitric acid. One part of toluol and 5 parts of nitric acid of 17° C. are introduced into a stoneware jar and heated in an autoclave, lined on the inside with aluminum, or constructed of enamelled iron, at a temperature of 130°-150° C., until the pressure is no longer increased. After cooling, the nitric oxide produced is allowed to escape (or collected for other technical use), and the residual
crystalline benzoic acid, which is contaminated with only small quantities of nitro compounds, is purified by the aid of reducing agents, washing, drying, and sublimation or distillation. An abundant yield of chemically pure benzoic acid, m. p. 121.5° C., is thus obtained.—Pharm. Ztg., lv (1910), No. 5, 47.

*Ammonium Benzoate—The Pharmacopœial Tests.*—From a comprehensive study and experimentation on the pharmacopœial tests for ammonium benzoate, Drs. Atherton Seidell and George A. Menge conclude that a simplified method of distillation based on that at present directed in the Pharmacopœia is sufficiently accurate for the quantitative analysis of ammonium benzoate samples. The litmus paper test is, however, inadequate for the determination of free benzoic acid present in amounts as great as approximately 10 per cent., and therefore misleading; while the melting-point, or rather decomposition point determination of ammonium benzoate is shown to be valueless as a test for the purity of this compound. The quantitative determination of ammonia by distillation is briefly described by the authors, in the present style of the Pharmacopœia, as follows:

"The ammonia from a weighed portion of about 0.5 Gm. of the sample, dissolved in H₂O, made alkaline with 50 Cc. of (\(\frac{N}{10}\)) NaOH, is distilled into 50 Cc. of (\(\frac{N}{10}\)) H₂SO₄, and the excess of the latter remaining after the distillation should require not more than 14.1 Cc. of (\(\frac{N}{10}\)) NH₄OH, using cochineal as indicator."—Amer. Journ. Pharm., Jan., 1910, 12-20.

*Saccharin—Confirmation of its Presence in Foods and Beverages.*—F. A. Genth, Jr., recommends the following method for the detection and confirmation of saccharin in 50 Cc. of a solution containing four milligrams of that substance in a liter: The absence of salicylic acid having been proven in a part of the residue from an ethereal extract, the remainder is dissolved in 1 Cc. of water made slightly alkaline with ammonia, transferred to a small crucible and evaporated to incipient dryness. A drop or two of water and a very small piece of NaOH are then added, and the whole quickly heated to dryness; when dry, the mass is further heated to fusion; after cooling, 1 Cc. of water is added, and the larger portion of alkali neutralized by HCl or H₂SO₄. After adding one or two drops of a 1 per cent. ferric alum solution, the neutralization is continued by dropping the acid from a fine pipette and stirring the solution. Operating in this way, where large amounts of saccharin were present, the violet color could be seen at the point of neutrality; in small quantities this point is frequently missed, but a careful back titration with a very dilute alkaline solution (very dilute ammonia, 1-20) generally indicated its presence.—Proc. Penna. Pharm. Assoc., 1909, 334-335.

*Sodium Cacodylate—Variable Hydration.*—P. Lemaire observes that the new French Pharmacopœia prescribes the anhydrous form of sodium
CITRIC AND TARTARIC ACIDS.

353
cacodylate, containing 46.87 per cent. of arsenium. Lately the com-
mercial form of the salt has generally contained two molecules of water, or 38 per cent. of arsenium; but other specimens have been met with on the market containing from two to five molecules of water.—Pharm. Journ.
and Pharmacist, Jan. 29, 1910, 109; from Répert. de Pharm., 27 (1909),
250.

Cinnamic Acid—Preparation and Properties.—G. Mossier says that cin-
namic acid, C<sub>6</sub>H<sub>5</sub>CH : CHCOOH, may be obtained from storax by distilling it with excess of alkali, when styrol and cinnamyl alcohol pass over; the so-
dium cinnamate is extracted from the non-volatile residue by hot water, and cinnamic acid precipitated from this by hydrochloric acid; it is puri-
ified by repeated solution in ammonium carbonate, reprecipitating by hydro-
chloric acid. It can be made synthetically from benzaldehyde, sodium acetate, and acetic anhydride by Perkin's reaction, or from benzal chloride and sodium acetate. Cinnamic acid is a colorless, tasteless, crystalline substance with a slight cinnamon-like odor, very little soluble in cold water, easily in hot water, alcohol, chloroform, ether, and fatty oils; melting-
point, 133°-135° C.; boiling-point, 300° C., with slight decomposition. An alcohol solution of the acid or an aqueous solution of the salt gives a yellow precipitate with ferric chloride, and a white precipitate with cal-
cium chloride; a hot solution, to which a little potassium permanganate is added, gives an odor of benzaldehyde. The acid should not show more than the faintest trace of chlorine if 0.5 Gm. is mixed with 2 or 3 Gms. of quicklime and ignited, the residue dissolved in dilute nitric acid, and tested with silver nitrate.

Sodium Cinnamate, identical with "Hetol," is obtained by neutralizing the hot aqueous solution of the acid with sodium carbonate. The ash of sodium cinnamate should not show more than faint traces of sulphate or chloride. Solutions of this salt should be sterilized within at most two or three hours of being prepared, or they will not keep; lime compounds should be entirely absent, and the heating should not be continued for more than ten minutes.—Pharm. Journ. and Pharmacist, June 11, 1910,

Citric and Tartaric Acids.—Examination for Impurities.—W. B. Cowie
examined several samples of citric acid for impurities in accordance with the suggestions in the report of the Committee of Reference to the Phar-
macopoeia Committee, and appends the results as follows:

Standards—Lead, 5 parts per million; sulphates, not more than would be produced by 5 Cc. BaCl<sub>2</sub> solution added to 1 Cc. \( \frac{N}{1000} \) H<sub>2</sub>SO<sub>4</sub> in 50 Cc. H<sub>2</sub>O.

23
With the exception of the first, and even it is on the border-line all are within the standard with every impurity except the lead.

Several samples of tartaric acid were similarly examined, the Committee of Reference standards being:

Lead, 10 parts per million; sulphates, as in citric acid. The results are:

It will be seen that No. 2 is the only one of the three which is within the standard, No. 1 having a large proportion of lead but otherwise good, No. 3 having an excessive proportion of lead and sulphate and calcium equal to the maximum allowed.—Chem. & Drugg., Dec. 25, 1909, 968.

**Magnesium Phospho-Tartrate.—Preparation and Properties.**—According to K. Sorger, magnesium phospho-tartrate may be prepared by three methods, (1) by treating magnesium phosphate with tartaric acid or magnesium acid tartrate; (2) by the action of phosphoric acid or magnesium acid phosphate on neutral magnesium tartrate; (3) by treatment of acid sodium phospho-tartrate with magnesium oxide. The salt is a tasteless, white powder, difficulty soluble in water and diluted acids, easily soluble in ammonia and diluted alkalies. It is not decomposed in the gastric juice, but becomes active in the intestines; it has no injurious effects and may be taken for prolonged periods. Pharm. Journ. and Pharmacist, August 14, 1909, 240; from Chem. Ztg. Rep., July 25, 1909, 382.

**Antimony and Potassium Tartrate—U. S. P. Assay Method.**—Virgil Coblentz and Otto B. May have made comparative experiments in order to determine the validity of recent criticisms on the part of manufacturers, to the effect that the U. S. P. iodometric assay of tartar emetic gives results that are uniformly too low. Using material of the highest purity, consisting of small white, partly effloresced crystals, which to secure uniformity were reduced to a fine powder, the antimony was determined both gravimetrically and electrolytically, and the results compared with that obtained iodometrically. These showed that each method yielded concordant results in three separate determinations by each, but that they do not agree among one another. Nevertheless, the difference is comparatively insignificant, the gravimetric estimations averaging 37.19 per cent. Sb = 103.18 per cent. pure salt., whilst the volumetric estimation averaged 36.94 per cent. Sb = 101.92 per cent. pure tartar emetic. These differences may be accounted for by the presence of small quantities of antimonic salt, and this might be taken into account either by lowering the purity rubric or the number of Cc. of iodine V. S. required in the present method of assay.—Merck’s Rep., Aug., 1909, 195.
Elateric Acid—Production from Elaterin by Caustic Alkali.—A. Berg finds that elateric acid (C_{29}H_{38}O_{7}), isomeric with elateridin, results from the action of caustic alkali on elaterin. At first elateridin and acetic acid are formed, but on boiling for half an hour with dilute alcoholic alkali the former is transformed into the acid. The process does not appear to be one of oxidation, since it occurs when oxygen is excluded. The conversion of the lactone into an acid is probably due to the transposition of a molecule of water. Elateric acid and its salts are amorphous; the alkali salts are very soluble in water and in alcohol. The silver salt is precipitated in a colloidal mass, resembling silica in appearance. It is soluble, when pure, in water, but is reprecipitated from solution on adding a little silver nitrate. The copper salt is insoluble in water, but very soluble in alcohol and in acetic ether, from which it is deposited on evaporation as a dark-green varnish.—Pharm. Journ. and Pharmacist, July 17, 1909, 73; from Compt. rend., 148 (1909), 1679.

Formic Acid—Quantitative Determination.—H. Franzen and G. Greve find that formic acid is best determined as follows: From 0.2 to 1.0 Gm. of the acid, in the form of a soluble formate, is dissolved in about a liter of water; fifteen times as much mercuric chloride, dissolved in 100 to 200 Cc. of hot water, is then added, with stirring. The vessel is kept in a water-bath at 95° to 100° C. until the precipitated calomel has settled; caustic soda is then added, with stirring, until the brownish-yellow precipitate (HgO) at first formed no longer redissolves, and heating in the water-bath is continued until the precipitate has settled. The addition of soda and the heating are then repeated, and after the second precipitate of mercuric oxide has settled, 20 Cc. of strong hydrochloric acid are added and the whole well stirred and again heated in the water-bath for an hour. The precipitated calomel is then collected in a Gooch crucible, well washed with hot water, dried for six hours at 95° to 100° C., and weighed; its weight multiplied by 0.097726 gives the weight of formic acid.—Apoth. Zeit., xxiv (1909), No. 91, 858.

Formic Acid and Formates—Volumetric Method of Estimation.—F. Auerbach and W. Pluddemann recommend a method for the volumetric estimation of formic acid, based on the reduction of mercuric chloride by formic acid, or formates, according to the equation 2HgCl_{2} + HCOOH → Hg_{2}Cl_{2} + CO_{2} + 2HCl. This reaction proceeds to completion if the concentration of hydrogen ions is not too great, and this is prevented by carrying out the reaction in presence of a sufficient quantity of sodium acetate. Mercuric chloride solution of known concentration is used, and the amount of formic acid present can be determined by estimating the quantity of mercuric salt still present after filtration from the precipitated mercurous salt. This can be effected by titration with potassium iodide, HgCl_{2} + 4KI = HgI_{2} + 2KI + 2KCl. The double iodide remains in solu-
tion until mercuric chloride is in excess, when the red mercuric salt begins
to separate. This happens, however, before the quantity of mercuric salt

This happens, however, before the quantity of mercuric salt corresponding with the above equation has been added, owing to the secondary reaction \( \text{HgI}_2,2\text{KI} + \text{HgCl}_2 \rightarrow 2\text{HgI}_2 + 2\text{KCl} \), which depends upon the relative concentrations of the salts in solution. The error due to this factor can be eliminated by titrating the mercuric salt into a definite quantity of potassium iodide solution of a certain standard strength. The deviations from the true stoichiometric relations having been experimentally determined for this particular quantity of solution of given strength and tabulated, it is easy to estimate the amount of mercuric chloride in any solution.—Pharm. Journ. and Pharmacist, Aug. 14, 1909; 240; from Arb. Kais. Gesundh. Amt., 1909, 30; through Journ. Reg. Inst.

**Juniperic and Sabinic Acids—Constitution.**—M. J. Bougault has determined in the course of further studies on the constituents of conifera wax that *sabinic acid* is to be regarded as being an oxylaurinic acid of the formula \( \text{CH}_3\text{OH}(\text{CH}_2)^{14}\text{COOH} \), and that *juniperic acid* is an oxypalmitic acid, \( \text{CH}_3\text{OH} \text{CH}_2(\text{CH}_2)^{14}\text{COOH} \). Furthermore, the author has shown that *thapsic acid* is identical with tetradecamethylen-dicarbonic acid, \( \text{COOH-} (\text{CH}_2)^{14}\text{COOH} \). These results establish in the three naturally occurring acids: palmitic, juniperic and thapsic, a very simple constitutional relationship, as is shown in the following:

- Palmitic acid = \( \text{CH}_2(\text{CH}_2)^{14}\text{COOH} \).
- Juniperic acid = \( \text{CH}_3\text{OH}(\text{CH}_2)^{14}\text{COOH} \).
- Thapsic acid = \( \text{COOH}(\text{CH}_2)^{14}\text{COOH} \).

—Pharm. Ztg., lv (1910), No. 47, 480; from Journ. de Pharm. et Chim., 1910, No. 9.

**Lactic Acid—Modification of Uffelmann’s Test.**—This test depends upon the observation that when a few drops of ferric chloride solution are added to 10 Cc. of a 2 per cent. phenol solution, the amethyst blue color produced under ordinary conditions is replaced by a lemon-yellow color if lactic acid is present even in small quantities. This reaction is also produced by citric and tartaric acid, but not by inorganic acid. It becomes far more delicate, however, according to Dr. Hugo Kühl, if the phenol solution is replaced by a cold saturated solution of salicylic acid, the test being made as follows: To 5 Cc. of a cold saturated solution of salicylic acid (1:100), 1 drop of ferric chloride solution (G. P.) is added. The handsome amethyst-blue color produced, immediately changes to an intense yellow color on the addition of strongly diluted solutions of lactic acid—the sensitiveness of the reaction increasing with the degree of dilution. Unfortunately the test cannot be regarded as characteristic for lactic acid, since, as experimentally determined by the author, the addition of citric, tartaric or oxalic acid produces the same reaction.—Pharm. Ztg., lv (1910), No. 12, 120.
Lactic and Glycollic Acids—Very Delicate Reactions.—G. Denigés finds that lactic acid, in presence of concentrated sulphuric acid, decomposes very easily and almost quantitatively, at the temperature of boiling water, with formation of aldehyde, which, when condensed with phenols and alkaloids of the morphine group, yields colored products, which afford a means of detecting lactic acid even in traces. In a test-tube 0.2 Cc. of a lactic acid solution (containing not more than 2 per cent. of the acid) is mixed with 2 Cc. of sulphuric acid of specific gravity 1.840. The mixture is heated on a boiling-water bath for two minutes, cooled, and then treated with one or two drops of five per cent. alcoholic solution of guaiacol or codeine, and then shaken. In the case of guaiacol a red-fuchsine tint is developed, still discernible as a rose coloration with 0.01 Mgm. of lactic acid in the same quantity of liquid; with codeine a red-yellow with concentrated solutions, and yellow with dilutions, is obtained. Treated under the same conditions, but at a higher temperature than that of boiling water, glycollic acid yields formaldehyde, for the detection of which codeine, guaiacol, or p-cresol may be used, in 5 per cent. alcoholic solution. Two to 10 Mgps. of the acid, 2 Cc. of water and 2 Cc., of sulphuric acid (specific gravity 1.840), are heated in a test-tube over a naked flame until there is a somewhat rapid disengagement of gas bubbles; on cooling a single drop of the codeine solution is added, and the mixture shaken, when there is developed a yellow coloration which quickly becomes deep violet. In the case of the other two reagents one or two drops of the alcoholic solution, and 1 Cc. of glacial acetic acid, are added to the mixture of glycollic acid and sulphuric acid before heating; on heating and shaking the mixture there is quickly produced, with the paracresol, a green or green-brown color, while with guaiacol the color is violet.—Pharm. Journ. and Pharmacist, July 24, 1909, 105, from Bull. Soc. Chim. 1909, 647.

Bismuth Salicylate—Quantitative Determination of Free Salicylic Acid.

In continuation of his experiments on the estimation of free salicylic acid in bismuth salicylate (see “Proceedings,” 1909, 367), J. Bristowe P. Harrison has experimented with various solvents and finds ether purificats, sp. gr. 0.720 (from methylated spirit), and chloroform to be the best solvents for the purpose of extracting the free acid with a minimum of decomposition of the salt. The ether is preferred owing to greater rapidity of work, but chloroform has the advantage that it dissociates the salt to a smaller degree. However, inasmuch as the amount of decomposition (practically 0.03 per cent.) by ether is constant, this can be corrected. Further experiments have led the author to the conclusion that there are at least two distinct bismuth salicylates on the market, one approximating to a true salt of salicylic acid, the other a more or less loose combination of the acid and base, so that the exact determination of free acid is, to say the least, a matter of extreme difficulty.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 303-311.
Sodium—Mercuriamido-oxyisobutyrosalicylate is a new mercury compound which is recommended for the subcutaneous administration of mercurials on account of its ready solubility and freedom from irritating or painful effects. It is an amorphous, faint yellowish, hygroscopic powder, containing about 40 per cent. of Hg, insoluble in alcohol and ether, but extremely soluble in water, forming solutions which are alkaline to litmus, but only redden phenolphthalein slightly. The compound possesses great stability, its aqueous solution keeping well when exposed to the air, while alkalis do not produce a precipitate even on heating. Ammonium sulphide also does not affect the solution at the ordinary temperature, until heated, or after prolonged standing. Acids, however, occasion an immediate precipitate. It may be administered as an antiluetic in doses of 0.1 to 0.15 Gm.—Apoth. Ztg., XXIV (1909), No. 97, 911.

Tribrompyrocatechin—Preparation. Tribrompyrocatechin is obtained under a German patent by the following simple process: 3.3 kgm. of pyrocatechin are suspended in 45 liters of chloroform and 14.4 kgm. of bromine, dissolved in 15 liters of chloroform, are gradually added with constant stirring, and refrigeration to a temperature of about 15°C. The reaction being completed when the bromine has completely disappeared. The product of the reaction is then separated by filtration, washed with water, dissolved in alcohol, and precipitated from its alcoholic solution by fractionation with water. Tribrompyrocatechin is so obtained in colorless, odorless crystals, containing 1 mol. of water of crystallization, and melting at 138° to 139°C.—Pharm. Ztg., LV (1909), No. 5, 47.

Organic Bases.

Alkaloidal Salts—Solubilities. George L. Schaefer has determined the solubilities of a number of alkaloidal salts in different solvents at different temperatures with results at variance with the figures given in the U. S. P.

Quinine Hydrobromide is not soluble in the proportion 1:16 in ether, but is very difficultly soluble requiring about 700 parts of solvent for solution.

Quinine Hydrochloride is not soluble in ether in the proportion of 1:240, but requires about 1000 parts of the solvent.

Quinine Salicylate is soluble in water at 25°C. in the proportion of 1:2100 and at 80°C., 1:280; in alcohol at 25°C., 1:23, and at 60°C. 1:5, in ether, 1:780; in chloroform 1:10.

Codeine Alkaloid is soluble in 25 parts of ether, not 12.5 parts.

Strychnine Alkaloid, at 25°C., is soluble in 150 parts of alcohol, or 7 parts of chloroform.

Strychnine Nitrate, at 25°C., requires 55 parts of water, or 220 parts of alcohol for solution.

Strychnine Sulphate is soluble in 45 parts of water at 25°C., but re-
quires only 9 parts at 80° C. It is soluble in 105 parts of alcohol at 25° C. —Amer. Journ. Pharm. May, 1910, 218-221.

The Assay Methods of the U. S. P., as applied to the more important alkaloidal drugs, are critically discussed by A. R. L. Dohme and H. Engelhardt, with particular endeavor to replace some of the more tedious ones by more expeditious and equally accurate methods. The paper appears in the "Proceedings," 1909, 879-886.

Alkaloids—Modification of Volhard's Method of Titration.—Referring to Volhard's method, Elias Elvove observes that the alkalimetric method of determining alkaloids is impeded by the fact that each indicator can be used only for one or a few alkaloids, but that by the use of alkaloidal hydrochlorides, the alkaloids may be indirectly determined by Volhard's method based on the titration of the hydrochloric acid. In continuation of previous studies, the author has applied the method to the determination of cocaine, morphine, codeine, narcotine, atropine, hydramine, pilocarpine, and brucine, and obtained in most instances and under varying conditions of concentration closely concordant results. The method, as conducted by the author, is as follows: The alkaloidal solution is treated with hydrochloric acid, evaporated on a water-bath to dryness, and then evaporated twice more after the addition of 5 Cc. of alcohol each time. The residue is now dissolved in water and titrated with $\frac{x}{10}$ potassium hydroxide, using phenolphthalein as indicator. If by this treatment the alkaloid is precipitated, the liquid is filtered, and in the filtrate after acidulation with nitric acid, the hydrochloric acid titrated according to Volhard's method.—Pharm. Ztg., lv (1910), No. 29, 294; from N. Chem. Zentralbl., 1910, No. 9.

Alkaloidal Salts—Indirect Determination by Titration of the Combined Acid.—E. Runne finds it practicable instead of determining the degree of hydration of alkaloidal salts by drying and weighing to make an indirect determination by titration of the combined acid. If a suitable indicator is used the acid may be titrated with $\frac{x}{10}$ alkali, just as if no alkaloid were present. Phenolphthalein is the best of the common indicators for the purpose, but a series of comparisons between phenolphthalein and Poirrier's blue (which is a weaker acid than the former), using alkaloidal salts of a known degree of purity, showed that the latter possesses certain advantages and gives very satisfactory indications. The alkaloid salt is dissolved in alcohol, from 2 to 5 drops of a 1 in 500 solution of Poirrier's blue are added, and $\frac{x}{10}$ alkali run in until the blue color changes to red; the small amount of alkali necessary to change the color of the indicator is ascertained by a blank titration and deducted. Morphine salts cannot be titrated in this way, either with this indicator or phenolphthalein, on account of the phenolic nature of the base.—Pharm. Journ. and Pharmacist, Oct. 23, 1909, 507; from Apoth. Ztg., xxvi (1909), No. 72, 662.
Alkaloids and Salts—Sulphuric Acid Test.—George L. Schaefer considers it important that the sulphuric acid test prescribed in the U. S. P. for a number of chemicals (chiefly alkaloids or their salts), should be carried out in distinct proportions of the substance and concentrated sulphuric acid to get uniform results in the hands of different experimenters. In his experience he has found the following proportions satisfactory:

0.01 Gm. of the Substance to 5 Cc. of Concentrated $H_2SO_4$.—Hyoscine hydrobromide; hyoscyamine sulphate; hyoscyamine; physostigmine sulphate; physostigmine salicylate; pilocarpine hydrochloride; pilocarpine nitrate; stryptine sulphate.

0.1 Gm. of the Substance to 10 Cc. of Concentrated $H_2SO_4$: Caffeine; cinchonidine sulphate; cinchonine sulphate; cocaine hydrochloride; codeine; codeine phosphate; codeine sulphate; morphine; piperine; quinine; quinine bisulphate; quinine hydrobromide; quinine hydrochloride; quinine sulphate; strychnine; strychnine sulphate.

In the case of atropine 0.02 Gm.; 5 Cc. should be used; in that of benzoic acid, 1 Gm.; 10 Cc. of $H_2SO_4$.—Amer. Journ. Pharm., May, 1910, 222.

Alkaloids—New Reaction with Hydrogen Dioxide.—Ed. Schär at a session of the Swiss Chemical Society on September 7, 1909, described several new reactions obtained with perhydrol (Merck's hydrogen dioxide) and solutions of certain alkaloids in concentrated sulphuric acid. Quinine gives an intense yellow color, which may reciprocally serve as a sensitive reaction for hydrogen dioxide. The reactions with perhydrol may be supplemented with Bredig's platinum solution, yielding with strychnine for example a permanent purple-red coloration. The entire series of opium alkaloids affords handsome color reactions. The new reagent also affords a convenient medium for the production of the murexid and other color reactions.—Schweiz. Wschr. f. Chem. u. Pharm., xlvi (1909), No. 40, 623.

Alkaloids—Nitro-Derivatives as Precipitants.—L. Rosenthaler and P. Görner state that, with the exception of o-nitrophenol and o-nitrocresol, the different nitro compounds investigated by them give characteristic precipitates with a large number of organic bases, although these reactions are not sensitive enough to make them available for alkaloidal determinations. The color of these precipitates, dependent on that of the reagents, exhibits all shades, from yellowish-white to deep orange-yellow and blood-red. The precipitates of mono-di- and triphenol are yellowish-white to lemon-yellow; dinitrocresol in general brownish-yellow, but with strychnine red; tetranitrophenolphthalein yields an orange-yellow, hexanitrodiphenylamine orange-red to brick-red precipitates. The precipitates produced by dinitro-a naphtholsulphonic acid are lemon- to orange-yellow, those of dinitroanthrachrysonsulphonic acid red-yellow to blood-red.
Nevertheless, many of these precipitates are sufficiently characteristic to be available for the determination of the alkaloids producing them. Such are arecoline, cinchonine, hordenine, hydastinine, cocaine, coniine and strychnine, while for berberine it is characteristic that its solutions gelatinize on addition of dinitro-α-naphtholsulphonic acid.—Pharm. Ztg., lv (1910), No. 47, 480; from Ztschr. f. anal. Chem., 1910, 343–357.

Betaine Hydrochloride—Synthesis.—According to G. Mossler, betaine, also known as oxyneurine, lycine, and trimethyl glycocol, and, in form of hydrochloride, chemically identical with acidol, may be prepared synthetically by the action of monochloracetic acid and trimethylamine. Commercially it is obtained by extracting the betaine from the residues of sugar-refining by means of strong alcohol, adding the calculated quantity of hydrochloric acid, and crystallizing from alcohol. Betaine hydrochloride occurs as colorless, odorless crystals, with strongly acid reaction and taste, easily soluble in water and dilute alcohol, slightly soluble in strong alcohol and insoluble in chloroform or ether. When warmed with alkali, it gives the herring-brine odor of trimethylamine. If exposed to the air for some hours the crystals must not become damp, showing absence of the poisonous neurine, the hydrochloride of which is hygroscopic. The absence of organic impurities may be shown by mixing small quantities with strong sulphuric and nitric acids, when a clear, colorless solution should be obtained in both cases. Ammonia is tested for by adding a few drops of Nessler's solution to a freshly-prepared solution of the salt, when not more than a yellowish tinge should be obtained, and no precipitate.—Pharm. Journ. and Pharmacist, April 16, 1910, 483; from Ztschr. Oesterr. Apoth. Ver., Feb. 5, 1910, 45.

Caffeine—Phenol Compounds.—A. J. Ute has prepared a number of compounds of caffeine with phenols, and by the use of equi-molecular quantities of their components obtained well-characterized addition components, particularly with pyrogallol and phloroglucin, from warm, concentrated aqueous solutions. Caffeine Pyrogallate crystallizes from warm water in needle-shaped crystals, melting at about 70°C. The compound is partly dissociated in aqueous solution, and permits the extraction of caffeine by means of chloroform.

Caffeine Phloroglucinate melts at about 185°C.

The author, furthermore, finds that theobromine is easily converted into caffeine by dissolving it in excess of sodium hydroxide solution, shaking the solution with a few drops of dimethyl sulphate and heating it moderately.—Pharm. Ztg., lv (1910), No. 20, 203; from Chem. Weekblad., 1910, pp. 32–34.

Caffeinum Citricum—Question of Its Chemical Identity.—The recent supply of alkaloidal caffeine by a German drug firm on an order for "caffein. citric." has elicited an interesting communication by Schmitt, from which it appears that it is a common practice of German wholesale drug
firms to list a "caffein. citric." and a "caffein. citric. ver. Ph. Brit." and to supply the alkaloid "caffeine" unless the order distinctly demands the caffeine. citric. verum. of the Ph. Brit. Furthermore, that the practice has been generally accepted by German pharmacists, who unhesitatingly disperse "caffein. purum" when "caffein. citric." is prescribed. This erroneous practice is doubtless due to the assumption, long held, that a true caffeine citrate does not exist; but the author points out that since the existence of the salt as a definite chemical compound has now been demonstrated by E. Schmidt, such substitution is, to say the least, reprehensible, and should be discontinued even if the designation "verum" is omitted.

Referring to the above, "F. S." mentions that the substitution of "caffein. citr." by "caffein. pur." is justified to a certain extent by the official list of synonyms appended to the Ph. Germ. III, in force until 1900, in which, on page 376, line 3 from above, occurs the following definition: "Caffeinum citricum . . . . Caffeinum." To avoid errors hereafter, the simplest way would be to admit caffeine. citricumin to the new (V) edition of the Ph. Germ.—Ibid., liv (1910), No. 103, 1014.

In reference to the preceding subject, Feuerabend calls attention to a possible justification of the substitution, depending on the interpretation of the abbreviation "Citr." Some eighteen years ago he was instructed on this point by his preceptor, who declared that the abbreviated adjective "citr." did not refer to "citricum," but to the lemon-yellow color, "citrium," of the caffeine formerly on the market.—Ibid., lv (1910), No. 4, 37.

With the object of cleaning up the controversy engendered by the preceding communications, concerning the existence or non-existence of caffeine citrate, etc., Hermann Schelenz contributes an interesting review covering the history of caffeine from its discovery by Runge in 1819-20. From this, the existence of caffeine citrate as a definite chemical compound must be regarded as indisputable, its formula being \(C_6H_{10}N_2O_4\)—\(C_6H_4O_7\), as determined by Gaze in the laboratory of E. Schmidt, in 1903. The Hungarian and British pharmacopoeias have since admitted and give formulas for caffeine citrate, whilst the U. S. P. also gives a formula for caffeina citrata (citrated caffeine), which designation Schelenz regards as the more appropriate. These preparations are not identical, but possess individual uniformity and are readily prepared by the pharmacist—all of them being based on the older idea of Hager, to effect simple mixtures of caffeine and citric acid in definite proportions.—Ibid., lv (1910), No. 9, 81-87.

_Cocaine and its Substitutes._—Differentiation.—C. Saporetti publishes the following table showing the reactions by which cocaine and its substitutes are differentiated, from which the reaction with calomel is here omitted, it sufficing to state that with the exception of Eucaine-\(\beta\) all the substances mentioned in the table have a reducing action upon it, as evidenced by the production of a gray color.

Caffeine Sodium Salicylate—Preparation and Properties.—According to G. Mossier, caffeine sodium salicylate is prepared by dissolving a mixture of equal weights of caffeine and sodium salicylate in water and evaporating to dryness; it forms a white odorless, amorphous powder, with bitter-sweet taste, soluble in water (1 in 2) and in alcohol (1 in 50), the watery solution being neutral in reaction. It answers the various tests for its constituents; to determine the proportion of caffeine present 1 Gm. is dissolved in 20 Cc. of water and the solution shaken out three times with chloroform; the caffeine left on evaporation of the chloroform is anhydrous, and should weigh 0.44 to 0.46 Gm., corresponding to 50 per cent. of caffeine containing one molecule of water. If the caffeine obtained from the substance is dissolved in water, a little caustic alkali added, and the solution shaken out with chloroform, the whole of the caffeine should be obtained again. This shows the absence of theobromine, which is not taken out of alkaline solution by chloroform.—Pharm. Journ. and Pharmacist, May 28, 1910, 677: from Ztschr. Algem. Oesterr. Apoth.-Ver., April 2, 1910, 141.

The Crystalline Alkaloid of Calycanthus Glauces is the subject of a third paper (in combination) by H. M. Gordin, which appears in the "Proceedings," 1908, 889–891. The same author contributes a preliminary paper on

The Alkaloids of Menispermum Canadense, which appears on pp. 891–892 of the same "Proceedings."

Cocaine Chloride—Precaution When Using Chloroform Water as Solvent.—V. Zotier states that cocaine hydrochloride only gives a clear solution with chloroform water if that is prepared with distilled water. If ordinary water has been used in the preparation of the chloroform water a turbid solution is produced. The turbidity is a function of the saturation of water by chloroform, and is due to the formation of a chloroform compound of the base cocaine which is liberated by the action of the calcium carbonate of the tap water on the cocaine salt. This compound is dissociated by acids and by water. Therefore the addition of a trace of acid or 10 per cent. of water will render the liquid clear.—Pharm. Journ. and Pharmacist, Oct. 9, 1909, 451; from L'Union Pharm., Sept. 1909, 398.

Cinchona Alkaloids—New Method of Distinction.—Denigés finds that if 0.2 Gm. quinine, cupreine, cinchonine or cinchonidine are dissolved in 2 Cc. of glacial acetic acid and 2 Cc. of pure concentrated sulphuric acid then added, a faint fluorescence is distinctly visible in all cases if viewed in a magnesium light. If then 2 Cc. of formaldehyde is added, cupreine and quinine are recognized by a distinct blue-green fluorescence, cinchonine a more blue, and cinchonidine a blue-violet fluorescence. On the further addition of 3 to 4 Cc. of water, the fluorescence in the case of cupreine disappears completely, but remains in the other alkaloids, that
of quinine being in fact augmented. The further addition of water causes the gradual disappearance of fluorescence in the case of cinchonidine, but that of quinine and cinchonine remains even in much greater dilution quite distinctly visible. The author believes these reactions to serve well for distinguishing the cinchona-alkaloids from each other.—Pharm. Ztg., liv (1909), No. 97, 957: from Rép. de Pharm., 1909, No. 11.

Cinchona Alkaloids and Their Salts—Solubilities in Water.—George L. Schaefer has determined the solubilities of the four principal cinchona alkaloids, and of all their available salts, in water at a temperature of 25° C., viz.—Quinine, and 32 of its salts; Cinchonidine, and 9 of its salts; Cinchonine, and 8 of its salts; Quinidine, and 8 of its salts. The author gives a description of the method and difficulties encountered in these determinations, and directs attention to the fact, that some of the salts are partly decomposed by water into a more soluble and a less soluble salt, which property, no doubt, has caused many of the discrepancies in previous determinations, carried out in different ways. For instance, 1 part of pure basic salt of quinine glycerophosphate of the formula \((\text{C}_a\text{H}_b\text{O}_c\text{N}_d\text{O}_e)_2\cdot\text{PO}_4\cdot\text{H}_2\cdot\text{C}_x\text{H}_y\text{O}_z + \text{H}_2\text{O}\) requires for complete solution about 850 parts of water of 25° C. If, however, a large excess of this salt is treated with water of 25° C. for several hours and frequently shaken, the solution filtered off from the undissolved part and tested, the salt will be found of much greater solubility, requiring even less than 200 parts of water for solution, according to time and quantity used. The remaining undissolved part, when dried and treated again with water in the same proportion and under the same condition as before, shows further decomposition, but in a lesser degree, and the solution will be found to contain considerably less of the salt than the first solution, and so on.—Amer. Journ. Pharm., April, 1910, 175-178.

Quinine Sulphate—Comparison of Pharmacopoeial Tests for Purity.—Frank Tutin has made a very exhaustive study of the tests prescribed in different pharmacopoeias for ascertaining the purity of quinine sulphate. The most important difference in conducting the "ammonia test," originally proposed by Kerner, as described in the U. S., French, Dutch and German Pharmacopoeias, is in the preparation of the saturated solution of the quinine salt. Thus, the French Pharmacopoeia states that one gramme of the hydrated quinine sulphate should be dissolved by boiling with 30 Cc. of water, after which the liquid must be cooled to 15° C. and then maintained at this temperature, with shaking, during half an hour. The Germ. Pharm. IV, on the other hand, requires 2 Gm. of the salt, dried at 40°-45° C., to be digested with 20 Cc. of water for thirty minutes at 60°-65° C., after which the mixture is cooled to 15° C., and then maintained at this temperature, with shaking, during two hours. In a similar way the aqueous solutions of quinine sulphate impurities are obtained by the U. S. and Dutch
Pharmacopoeias, and they all demand that 5 Cc. filtrate should require a specified minimum quantity of 10 per cent. ammonia solution to clear up the precipitate occasioned by such addition: U. S., 7 Cc.; French, 5 Cc.; Dutch, 4.5 Cc., and German, 4 Cc., as a minimum. The author's experiments, the details of which must be consulted in the original, lead him to the conclusion that the method of applying the ammonia test to quinine sulphate, as described by the French Pharmacopoeia, is to be preferred to that given by the other pharmacopoeias, but that the standard of the French, as well as of the German and Dutch Pharmacopoeias, are too stringent, and that a minimum of 6.0 Cc. when conducting the test according to the French method would seem a reasonable requirement. The usefulness of the ammonia test is, however, limited, and the author therefore questions whether the test of the British Pharmacopoeia, for cinchonine and cinchonidine by means of purified ether, etc., is not to be preferred.—Pharm. Journ. and Pharmacist, Nov. 13, 1909, 603.

**Quinine Tannates—True and False Kinds.**—Biginelli points out the distinction between true quinine tannates, which are definite chemical compounds, and false quinine tannates, which are simply addition-products of tannin with quinine salts used for precipitation. In the latter, for example, the sulphuric acid derived from the quinine sulphates used may be determined in the hydrochloric acid solution of the sample.

**Tasteless Quinine Tannate** he now finds to be a mixture of four true quinine tannates, namely: Tetraquinine Pentannate, Biquinine Ttranannate, Biquinine Tetratannate and Biquinine Pentannate. The true quinine tannates must respond to the following reaction: If 0.1 to 0.2 is moistened with moderately strong hydrochloric acid, then diluted after a few minutes with 2 to 3 Cc. of water and evaporated to dryness, the residue of evaporation should be soluble in 20 Cc. of water.—Pharm. Ztg., liv (1909), No. 74, 726; from Gazz. Chim. Ital.

**Quinine and Urea Hydrochloride—Properties.**—In view of the importance of quinine and urea hydrochloride has recently gained as a local anesthetic and the paucity of information regarding this compound, George L. Schaefer makes some practical observations concerning its properties and gives some tests for its identification and purity. Theoretically this salt requires 50.24 per cent. anhydron quinine, 10.98 per cent. urea, 13.32 per cent. hydrochloric acid, and 16.46 per cent. water, but the preparation on the market usually contains 2 to 3 per cent. less of water of crystallization than is required by the formula: \( C_{29}H_{24}N_2O_2(HCl)_2 + CO(NH_2)_2 + 5H_2O \). It crystallizes in hard and nearly colorless prisms from water and from alcohol in soft, needle-shaped crystals, but for convenience is usually supplied in form of a white powder, soluble in its own weight of water and in 2.5 parts of alcohol. Soluble in chloroform, but partly decomposed thereby; practically insoluble in ether. By prolonged heating at
125° C. the salt becomes anhydrous, and then melts almost completely at 180° C, with decomposition at about 190° C. Drugg. Circ., Febr., 1910, 55-56.

Ergothionëine — A New Alkaloid from Ergot.—By a circumstantial method which excludes the other associated bases, Ch. Tanret has succeeded in isolating a new base from ergot, which he has named ergothionëine—the yield from 1 kilo of the drug being about 1 Gm. When purified completely by the aid of calcium carbonate and strong alcohol, in which the base is scarcely soluble, and recrystallization from 60 per cent. alcohol, ergothionëine has the composition corresponding to the formula C₉H₁₅N₃O₂S₂H₂O. On drying over sulphuric acid it loses its water of crystallization, which is again assimilated on exposure to the air. It crystallizes in form of leaflets and in needles, but in the latter only in the presence of CaCl₂ as impurity; is soluble is 8.6 p. of cold water, freely in hot water and in weak alcohol, but very sparingly soluble in strong alcohol, in methyl alcohol and in acetone, and insoluble in ether and in chloroform. The aqueous solution of the base is dextrorotatory. It is a feeble, non-volatile base, giving no reaction with litmus, but readily forms crystallizable salts, a number of which—the hydrochloride, sulphate, hydroxide, etc.—have been prepared. They are characterized by their acid character, and give the alkaloid reactions with the usual reagents, with the exception of picric acid and tannin—the latter producing a precipitate only in very concentrated solutions of the base. When freshly prepared, ergothionëine is odorless, but on keeping it acquires a disagreeable odor. When melted with alkali and then acidulated, H₂S is evolved. Its solution when heated with KOH and chloroform acquires a green color, which on neutralization changes to blue.—Pharm. Ztg., liv (1909). No. 67, 651; from Journ. de Pharm. et Chim. 1909, No. 4.

Gelsemine Hydrochloride and Gelseminine have been subjected to further examination by L. E. Sayre, who communicates the results of his observation in a paper published in the “Proceedings,” 1909, 902—903.

Guanidine Perchromate—Preparation and Properties.—According to K. A. Hoffmann and K. Buchner, guanidine carbonate yields with chromic acid anhydride and hydrogen peroxide a perchromate of the formula CrO₃H₂C₅N₅H₁₅.H₂O. It forms brownish-yellow prisms, which can be kept in a dry state for weeks and are not explosive. It dissolves in water, and its solution when boiled gives up oxygen and leaves a yellow solution of guanidine chromate. When treated with ether and acidified an intensely blue-colored ethereal solution of perchromic acid, CrO₃H, is obtained. From its reactions it may be concluded that guanidine perchromate belongs to the class of red perchromates for the acid of which Riesenfeld gave the constitutional formula O₂ : Cr : (O₃H)₃ with heptavalent chromium.—Chem. News, Oct. 22, 1909, 208; from Ber. d. D. Chem. Ges., 42 (1909), No. 12.
Jesaconitine—A New Alkaloid from Japanese Aconite Root.—K. Makoshi has isolated a new alkaloid,jesaconitine, from the “Bushi” roots (Kusauzu roots of Hokkaido; \textit{Aconitum Fischeri}, Reich.), and obtained a well-crystallized acetyl derivative from it. On hydrolysis,jesaconitine yields benzoic acid, anisic acid, and aconine. Anisic acid as a decomposition product serves to distinguishjesaconitine from all other aconite bases. The aconine is identical with that obtained from the aconitine of \textit{Aconitum napellus}. \textit{Japanconitine}, from \textit{A. Fischeri}, of Hondo, is essentially different from thejesaconitine of the “Bushi” roots. It melts at 202° to 203.5° C., while the aconitine of \textit{A. napellus} melts at 197° C., and it is more difficult to obtain in crystalline form than aconitine. The formula attributed to it is \( \text{C}_{28}\text{H}_{39}\text{NO}_{11} \).—Pharm. Journ. and Pharmacist, Aug. 7, 1909, 205; from Ztschr. de Allgem. Osterr. Apoth.-Ver., 1909, 229.

Nicotine—Estimation for Technical Purposes.—The increasing use of tobacco for combating the infections on grape wines has given the incentive to F. Porchet and F. Régis to study the different methods proposed for the estimation of nicotine. Comparative experiments with Schlossing’s method (extraction of nicotine by ether in the presence of sodium chloride), the method of Biel (extraction by steam and separation of the alkaloid from ammonia in form of sulphate), and that of Toth (absorption of the ammonia by calcium sulphate and direct separation of the nicotine by means of a mixture of ether and petroleum ether), have convinced the authors that the method of Toth is not alone preferable to the other two mentioned, but well adapted and sufficiently accurate for the technical purposes contemplated—the more particularly since the method excels in celerity.—Pharm. Ztg., liv (1909), No. 102, 1007; from Chem. Ztg., 1909, No. 127.

Nupharine—Instability.—A. Goris and L. Crété have experimented with the alkaloid “nupharine” which Gruning has isolated from the rhizome of Nuphar luteum. It has the composition \( \text{C}_{15}\text{H}_{24}\text{O}_{2}\text{N}_{2} \), and occurs as a friable white mass, caking when heated at 40°–45° C., and melting at 65° C. to a syrupy condition. The hydrochloric or acetic solution of the alkaloid undergoes decomposition in a vacuum over sulphuric acid with formation of a strong and peculiarly odorous substance. As obtained by the authors from the fresh rhizome, the hydrochloric solution gives a brown precipitate with Bouchardat’s reagent, an orange-red one with Dragendorff’s, and a milk-white one with Mayer’s reagent. Pharm. Ztg., lv (1910), No. 39, 397; from Journ. Chem. Soc., London, 97, 220–223.

Opium Alkaloids—Degree of Representation in the Official (Ph. Nerland) Opium Preparations.—Marie van de Kreke and Francine Swart have determined the morphine, narcotine and codeine extracted by the different solvents directed for certain preparations of opium of the Ph. Nerland namely: Extr. opii, Tinct. opii, and Tinct. opii croc. The
results show that morphine is almost completely extracted by aqueous as well as alcoholic menstrua. The same is true of alcoholic solvents for narcotine and codeine, but these are only partially represented in aqueous extractions. Pharm. Ztg., lv (1910), No. 18, 181; from Pharm. Weekbl., 1909, 1338–1342.

**Apomorphine—Contamination with Trimorphine.**—Prof. Erich Harnack and Dr. H. Hildebrandt, having their attention drawn to commercial apomorphine of questionable appearance, subjected specimens of the suspected article to chemical examination. The results showed that all the samples differed from pure apomorphine, and also from each other, but that they all contained, in admixture with true apomorphine, more or less trimorphine as hydrochloride \((\text{C}_{17}\text{H}_{19}\text{NO}_3\text{HCl})_3\), or possibly some other polymeric form of morphine. The contaminated apomorphine is characterized as being a snow-white crystalline powder, forming faintly acid aqueous solutions which, in distinction from pure apomorphine, become barely or not at all green on standing. Physiologically this impure article differs likewise, and is believed by the authors to be responsible for most of the poisonous effects that have been attributed to apomorphine.—Pharm. Ztg., liv (1909), No. 95, 938–939.

**False Apomorphine Hydrochloride—Practically Composed of Trimorphine Hydrochloride.**—G. Frerichs has also examined two specimens of suspicious apomorphine hydrochloride, the one supplied by a Berlin manufacturer, the other by a Frankfort A. M. firm, and finds them to consist practically of trimorphine hydrochloride with, at most, only traces of true apomorphine. The false preparation is easily distinguished from true apomorphine hydrochloride in being non-crystalline and by its extreme solubility in water, requiring only an equal weight for solution whereas apomorphine hydrochloride requires 40 parts of water. In other respects, the pharmacopœial tests give no marked criterion of distinction, only in so far as the solution of true apomorphine in sodium hydroxide (which is incomplete in either case (darkens more rapidly than the corresponding solution of the false preparation, and that the precipitate occasioned in solution of apomorphine by sodium bicarbonate assumes a green color quite rapidly while that from the false preparation scarcely shows any change. The distinction of the two preparations on the basis of crystallinity and non-crystallinity is difficult because the false preparation, when examined under the microscope, exhibits minute snow-white, glistening aggregations, appearing colorless and transparent by transmitted light. The author describes a number of parallel reactions of the two preparations which however serve for the recognition of false apomorphine ( = trimorphine) only if true apomorphine is absent. On the other hand, taking advantage of the practical insolubility of true apomorphine hydrochloride in diluted hydrochloric acid, while the false article is readily
soluble, the detection of the latter in admixture with the true article is easily accomplished as follows: 0.1 Gm. apomorphine hydrochloride, placed upon a small dry filter, is treated with 5 Cc. of a mixture of 1 p. hydrochloric acid and 4 p. water, and the filtrate tested with potassium-mercuric iodide. Pure apomorphine hydrochloride gives at most an opalescent turbidity, whereas in the presence of other alkaloids, which are soluble in hydrochloric acid, distinct precipitation results; an admixture of 10 per cent. of the false apomorphine producing an abundant curdy precipitate.—Apoth. Ztg., xxiv (1909), No. 99, 928–929.

**False Apomorphine Hydrochloride—Presence of True Apomorphine.**—Harnack and Hildebrandt, referring to the observations of Frerichs concerning "false" apomorphine hydrochloride (see preceding abstract), speak commendably of the hydrochloric acid test proposed by the latter for determining the presence of foreign alkaloids (and with these, of course, trimorphine) in true apomorphine hydrochloride. They contend, however, that Frerichs has overlooked the presence of true apomorphine in the preparations examined by him, and confirm this by actual experiments, which prove that the presence of trimorphine prevents the precipitation of apomorphine by hydrochloric acid within wide limitations. Thus, a crystalline precipitate of apomorphine hydrochloride results when equal volumes of concentrated hydrochloric acid and of 1 per cent. solution of a mixture of 2 parts of apomorphine and 3 parts of trimorphine are mixed; but if the relation of the two bases is 2:4, then no precipitate results at all. Experiments made with false apomorphine and pure apomorphine, mixed in certain proportions, confirmed this completely. Mixed in the proportions of 1:3, precipitation barely resulted; while larger proportions of the false preparation prevented it entirely. The authors conclude that the false apomorphine under examination did not contain much over 20 per cent. of true apomorphine. These corrections of Frerichs's findings, however, do not invalidate the test which he proposes for determining the presence of foreign alkaloids (trimorphine, etc.) with which the apomorphine is associated, since the object of the test is not to determine the presence of apomorphine, but that of the foreign bases contaminating it. Aside from other considerations, the authors emphasize that while apomorphine is emetic in its action, the pharmacologic activity of trimorphine is morphine-like, and that consequently the false article is absolutely unsuited as a substitute for true apomorphine hydrochloride.—Pharm. Ztg., lv (1910), No. 1, 6–7.

**Morphine Salts—Development of Volatile Odorous Bodies.**—C. Reichard having on a previous occasion called attention to the emanation of a peculiar odor during certain morphine reactions, has recently again noticed this odor during experiments undertaken for the purpose of establishing new reactions for morphine. Following up the observation experi-
mentally, he has determined that an extremely faint musk-like odor is uniformly developed when solution of morphine salts are heated, and that even the salts themselves emanate this odor when carefully heated. The intensity of the odor is increased by the concentration as well as the quantity (extent of surface) of the solution. Speculating upon the cause of this odor, the author considers it probable that it is due to the minute volatilization of the morphine salts with the water vapor, or, possibly by the formation and volatilization of free acid; but no positive deduction is at present available.—Pharm. Zentralh., 51 (1910), No. 7, 128–130.

**Papaverine—Synthesis.**—Goldschmidt has shown that the constitution of papaverine, which must be regarded as one of the most important of the opium alkaloids, is comparatively simple. Amé Pictet, in collaboration with A. Gams, has now succeeded in preparing it synthetically, as follows:

—By the action of acetyl chloride on veratrol in the presence of aluminum chloride, acetoveratrol (I) is formed, which yields with nitrous acid an isonitroso derivatives (II) and this is with stannic chloride reduced to aminoaetoveratrol chlorhydrate (III). Then, starting with vanillin, the methyl derivatives of which yield hydrocyanic acid an oxy acid nitrite (IV), this yields on boiling with hydrogen iodide, removal of the methyl groups, saponification of the cyanogen and reduction of the hydroxyl, homoprotocatechuic acid (V), which is again methylated and converted into the chloride (VI). The base (III) and the acid chloride (VI) are now caused to react on each other and the product of the combination (VII) by reduction with sodium amalgam in alcoholic solution, maintained acid with acetic acid, is converted into the corresponding alcohol base (VIII). To complete the synthesis, the latter is now subjected to hydrolysis by boiling with phosphorus pentoxide in xylol solution. The papaverine so obtained proved to be identical in all respects with the natural base.—Schweiz. Wschr. f. Chem. u. Pharm., xlvii (1909), No. 40, 621–622.

**Physostigmine—An Intensely Fluorescent Derivative.**—F. Gaubert draws attention to a body derived from physostigmine whose red fluorescence surpasses that of all known substances. An aqueous solution of physostigmine is allowed to stand for several months until it becomes of a dark blue color. On adding hydrophthalic acid, a blood-red fluorescence is developed. The production of this color is at once a distinctive test for either substance. The crystals of this new body are deep blue in color. Meconic acid in crystals, silk, cotton, alcohol, ether, etc., are also colored blue by it, but there is no fluorescence in these cases. On the other hand, aqueous solutions of the crystals sufficiently diluted to be only faintly blue, almost colorless, by transmitted light, show by reflected natural light a red tint comparable to that of very fine rubies.—Pharm. Journ. and Pharmacist, Febr. 26, 1910, 237; from Compt. rend., Nov. 15, 1909, 852.
Scopolamine—Influence on the Action of Morphin.—A. Friedlander finds that scopolamine increases the sedative and calmative action of morphi ne in a remarkable manner, and renders active minute doses which, alone, would be without effect. On the other hand, morphin acts as an antidote to scopolamine; and the latter should never be prescribed with the former, so that the disagreeable effects of scopolamine, when given alone, may be avoided. Scopolamine-morphine is specially indicated for cases in which there is excitement of the central nervous system, or for the treatment of long-standing neuralgias, where secondary morphinism may result from the frequent use of morphin alone. Its use is also suggested in chronic morphinism, since it allows the dose of morphin greatly to be reduced, and that of scopolamine increased. Habitual morphinism is not likely to occur with the use of the combined injection. It must, however, be practiced under assiduous observation, with due attention to the idiosyncrasy of the subject. As a commencement \( \frac{1}{20} \) grain of morphin and \( \frac{1}{4} \) grain of scopolamine may be injected. When the effect of this is lessened the amount of scopolamine may be cautiously raised, then, if necessary, that of the morphin.—Pharm. Journ. and Pharmacist, Sept. 4, 1909, 319; from Nouv. Remèdes, 26 (1909), 295.

Strychnine.—Derivatives and Characteristic Reaction.—According to Paul Malaquin a distinct and characteristic reaction of strychnine in solution of \( \frac{1}{100000} \) is obtained as follows: To a mixture of \( \frac{1}{1} \) Cc. of the liquid under examination and \( \frac{1}{1} \) Cc. of pure hydrochloric acid some granulated zinc (just previously treated with \( \text{HNO}_3 \) and well washed with water) is added. After the evolution of hydrogen for several minutes, the mixture is quickly heated to boiling, cooled by immersing the test tube in water, and a substratum of concentrated sulphuric acid is introduced, when, in the presence of strychnine, a rose-red ring forms at the zone of contact of the two liquids, either at once, or after a few minutes. This color increases in intensity and finally permeates the entire liquid, which is then heated to boiling. The color so produced is permanent and does not disappear on boiling, but disappears on the addition of a few drops of 10 per cent. solution of potassium sulphocyanide, and also with an excess of ammonia—reappearing, however, in the latter case, on supersaturation with \( \text{H}_2\text{SO}_4 \).—Pharm. Ztg., liv (1909), No. 102, 1007; from Jour. de Pharm. et. Chim., 1909, No. 62.

Strychnine and Brucine—Effectual Separation in Nux Vomica Assays. In consequence of the unfavorable criticisms regarding the efficiency of the U. S. P. method of separating strychnine from brucine in the assay of nux vomica and its preparations, and the suggestion that the difficulties encountered may be overcome by the presence of nitrous acid in the nitric acid employed, G. Pinchbeck, after a considerable amount of experimental work, finds that excellent results are obtained by the employ-
ment of a solution of nitrogen peroxide in nitric acid instead of ordinary nitric acid (sp. gr., 1.42). The solution is prepared by diluting commercial fuming nitric acid in such proportion as to contain 1 per cent. of nitrogen peroxide, N₂O₅, and not less than 70 per cent. of real HNO₃. In the practical process, the details of which are given, the exposure of the mixed alkaloids to the action of this acid solution for fifteen minutes suffices for the complete destruction of the brucine. The particulars requiring attention in the assay are: (1) The oxidation should not be allowed to proceed beyond the time indicated, otherwise loss of strychnine occurs. (2) The strength of fuming nitric acid should be adhered to. (3) The directions regarding the final drying of the alkaloid should be observed.—Trans. Brit. Pharm. Conf. (Yearbook of Pharmacy), 1909, 327–331.

Theobromine—Determination in Theobromine-Sodium Salicylate.—E. Anneler's experiments show that the G. P. Method for determining the theobromine in theobromine-sodium salicylate does not give absolutely accurate results, the error under the most careful manipulation amounting to about 4 per cent. of the amount of theobromine found. He has tried other methods, which are more or less inaccurate within 0.1 per cent., if the following directions are carefully adhered to:—1 Gm. of theobromine-sodium salicylate is dissolved in 10 Cc. of water and rinsed into a small separator with a little more water; 3 Cc. of 10 per cent. HCl and a drop of phenolphthalein solution are added, followed by sufficient of a concentrated aqueous solution of barium hydroxide to saturate the liberated salicylic acid, until the red color of the indicator just remains perceptible after admixture. The mixture is then shaken out successively with 20, 10, 10, and 10 Cc. of a 20 per cent. solution of phenol in chloroform, drawing off the first portion after the separation into two layers, and collecting the phenol-chloroform solutions, through a small filter, in a tared glass evaporating dish. The phenol and chloroform are evaporated to dryness in a water bath and the residual theobromine, which is perfectly pure and free from barium salicylate, is weighed. The operation requires very little more time than the method directed in the German or Swiss Pharmacopoeias and is preferable because more exact.—Pharm. Ztg., lv (1910), No. 20, 205.

Urea—Theoretical Relation to Formic Acid.—Paul Stoepel points out that urea and its nearest relative, carbamic acid, together with their derivatives, do not occupy the proper place in theoretical chemistry. Carbamic acid is usually regarded as the monamide and urea as the diamide of carbon dioxide, instead of with the theoretical and physiologically more closely related formic acid. Urea, and its derivatives, are more accurately defined as amido-derivatives of formic acid than, as heretofore, as amido-derivatives of carbon dioxide. Accordingly, also, ammonium carbonate with ammonium carbamate is more correctly defined as ammonium amido formate = NH₂CO.O.NH₄,—Apoth. Ztg., xxv (1910), No. 16, 129.
Alkyl Iodides—Action on Mercury-Ammonium Salts.—M. Zipkin finds that if ethyl iodide is left in contact with ordinary “white precipitate,” NH₂HgCl, for several months, yellow crystals of a double iodide of mercury and tetraethylammonium are obtained, their composition being represented by the formula 2N(C₂H₅)₄I₃HgI₂; the same compound is obtained by heating white precipitate with ethyl iodide and ethyl alcohol in a water-bath together with a larger quantity of double iodide of mercury and ammonium, NH₄I₃HgI₂. “Fusible white precipitate” (NH₃)₂HgCl₂, heated with methyl iodide and methyl alcohol, gives a double iodide of mercury and tetramethyl-ammonium N(CH₃)₂I₃HgI₂, together with the double iodide of mercury and ammonium and a little ammonium chloride. Oxydimercuri-ammonium chloride, NH₃HgCl₂HgO, heated with methyl iodide, gives yellow crystals of double iodide of mercury and tetramethyl ammonium, having a different melting point from the compound obtained from fusible white precipitate. The production of tetra-alkyl-ammonium compounds suggests that the formulae NHgCl, NHgCl for white precipitate, NHg₂Cl₃NHCl, for fusible white precipitate, and NHg₂Cl₂H₂O, or oxydimercuri-ammonium chloride, are more correct than those given above, which are usually assigned to them. On the other hand, when one of these compounds is dissolved in solution of sodium thiosulphate, the nitrogen is entirely given off as ammonia, whereas ammonium chloride or salt alembroth evolves no ammonia when dissolved in thiosulphate, and it therefore appears unlikely that the white precipitates contain ammonium chloride. Thus, the experiments recorded do not enable a decision to be made between the alternative formulae.—Pharm. Journ. and Pharmacist, Oct. 23, 1909, 507; from Apoth. Ztg., xxiv (1909), No. 72, 662.

Antipyrine—A Sensitive Reagent.—Primot finds a solution composed of 1.0 vanillin, 6.0 of ½ N hydrochloric acid and 100.0 of 95 per cent. alcohol to be an extremely sensitive reagent for antipyrine. If 1 Cc. of this reagent is added to a trace of antipyrine in a porcelain dish and evaporated on the water-bath, a deep orange-colored ring is developed, culminating in a spot of the same color. Under careful observation it is possible to detect so infinitely small a quantity as 0.00095 Mgm. of antipyrine by means of this reagent, which serves well for its detection in pyramidon, since the latter does not give the reaction.—Pharm. Ztg., liv (1909), No. 54, 530; from Bull. Scienc. Pharmacol., 1909, No. 5.

Arsen-aniline Tartrate—Preparation and Properties.—According to M. P. Yvor, arsen-aniline tartrate (C₄H₅O₆AsO.C₆H₄NH₂) is obtained by the action of 93 p. aniline and 99 p. arsenic trioxide on a solution of 150 p. tartaric acid in 350 p. water, evaporating the solution to syrupy consistence and allowing it to coal. The new salt separates in form of greenish-yellow to rose-colored crystals (rarely white) which are anhydrous, and are isomorphous with “antimonyl-aniline tartrate (which are under “New Reme-
Basic Periodides—Formation and Properties of Some New Compounds. —A. Linaris describes a number of new basic periodides as follows:

Tetraiodide of ethylenediamine hydroiodide, \( \text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2\cdot2\text{HI} \), is obtained by adding solution of iodine in potassium iodide to a solution of ethylene diamine in water containing hydriodic acid. The greenish precipitate is warmed in the mother liquor with a little added potassium iodide until dissolved. On slowly cooling fairly large grayish crystals, with a metallic aspect, separate. Melting-point, 218° C.

Tetraiodide of piperazine hydroiodide, \( \text{C}_6\text{H}_{10}\text{N}_2\cdot2\text{HI} \), is similarly prepared. It forms fine steel-blue crystals, melting at 280° C. It may be obtained either with the free base, its sulphate, or its hydrochloride. The hydrated form containing three molecules of water results from the solution of the above in potassium iodide solution. It melts at 283° C.

Tetraiodide of benzidine hydroiodide, \( \text{C}_17\text{H}_{12}\text{N}_2\cdot2\text{HI} \), forms black crystals with a metallic luster, melting at 298° C.

Tri-iodide of piperidine hydroiodide, \( \text{C}_8\text{H}_{11}\text{N} \cdot \text{HI} \), is similarly prepared with ice-cold solutions. Green crystals, melting at 45° C., are obtained. On operating at ordinary temperatures a green oil is the result.

Tetraiodide of piperidine hydroiodide, obtained by using solutions in the appropriate proportions, cooled in a freezing mixture forms green crystals with a metallic luster, melting at 35° C.

Di-iodide of pilocarpine hydroiodide, \( \text{C}_17\text{H}_{16}\text{N}_2\cdot\text{O}_2\cdot\text{HI} \), forms red crystals with a metallic luster, melting at 148° C. The tetraiodide, \( \text{C}_11\text{H}_{16}\text{N}_2\cdot\text{O}_2\cdot\text{HI} \), gives greenish-black crystals, melting at 135° C.

Di-iodide of ethylmorphine hydroiodide, \( \text{C}_19\text{H}_{23}\text{NO}_3\cdot\text{HI} \), gives ruby-red crystals, melting at 150° C.

Tri-iodide of xanthine hydroiodide, \( \text{C}_8\text{H}_4\text{N}_2\cdot\text{HI} \), occurs in small green crystals, which have no definite melting-point.—Pharm. Journ. and Pharmacist, Oct. 9, 1909, 451; from Journ. de Pharm. et Chim., 30 (1909), 241.

Quinoline Sulphosalicylate—Composition and Properties.—According to "Journ. de Pharm. et de Chim." (1910, No. 11) quinoline sulphosalicylate is obtained by the action of quinoline and sulphosalicylic acid on each other in the presence of water, forming white crystals, in silky tufts, having the composition \( \text{C}_9\text{H}_4\text{SOH}—\text{OH}—\text{COOH}—\text{C}_9\text{H}_4\text{N}—\text{H}_2\text{O} \). It conglobates at 110° C., losing 1 mol. of water and melts at 220° C. The salt has acid reaction, is only sparingly soluble in cold water, but readily solu-
ble in hot water and in alcohol, while in ether or chloroform it is almost insoluble.—Pharm. Ztg., lv (1910), No. 46, 472.

*Quinesol—Characters and Tests.*—According to F. Zernik, quinesol (neutral orth-oxyquinolone sulphate) should be a light yellow, crystalline powder, with a saffron-like odor, and a burning taste. Melting-point, 175° to 177.5° C. Readily soluble in water; sparingly so in ether. The 1 : 50 aqueous solution is acid in reaction; a drop of ferric chloride reagent gives an intense green color with it, and barium chloride a white precipitate. Sodium carbonate liberates ortho-oxyquinolone as a white precipitate, forming felted needles on standing. When these are collected, washed, and dried they should melt at 73-75° C.—Pharm. Zentralh., 50 (1909), No. 37, 771.

*Hydroxylamine—Alkalimetric Determination.*—Arthur Stähler recommends the following alkalmetric method for the determination of hydroxylamine: Purified hydroxylamine hydrochloride is dissolved in water, and strongly acid titanium trichloride (or sesquisulphate) solution is added till a faint pink coloration remains after shaking. The ammonia thus formed is distilled off and received into a known volume of $\frac{\text{N}}{10}$ acid. This method can be used to determine all organic nitrogen-oxygen compounds (hydroxylamine, oximes, nitro- and nitroso-bodies) which are converted by trivalent titanium into volatile amines which can be titrated with acids.—Chem. News, Oct. 22, 1909, 208; from Ber. d. D. Chem. Ges., 42, (1909), No. 12.

*Tetra Hexamethylenetetramine—Compounds with Mercury Salts.*—Ed. Schmitz finds that if solutions of 5.42 Gm. mercuric chloride in 1000 Cc. water and 1.4 Gm. hexamethylenetetramine in 500 Cc. water are mixed, white needle-shaped crystals are deposited in a few minutes having the composition after washing and drying of $(\text{CH}_2)_6\text{N}_4\cdot\text{HgCl}_2$. This compound is sparingly soluble in water and alcohol, but dissolves readily in water on addition of ammonium chloride, probably forming a double salt. On heating the aqueous solution above 80° C., however, decomposition sets in, HgCl being deposited. The corresponding *mercuric iodide* compound is formed by mixing solutions of 0.9 Gm. mercuric iodide in 250 Cc. alcohol and of 0.14 Gm. hexamethylenetetramine in 50 Cc. alcohol, when, in the course of 15 to 20 minutes small yellowish-white needles will be deposited. By the use of *mercuric sulphate* in a similar way a hexamethylen mercuric sulphate may also be obtained.—Pharm. Ztg., lv (1910, No. 46, 471; from Ber. d. D. Chem. Ges., 1910, No. 4.

*Phenolphthalein—Proposed Official Recognition as a Therapeutic Agent.*—Dr. P. E. Hommel, in view of the recent observations that phenolphthalein produces in ordinary doses, copious evacuations without any disagreeable by-effects, and its consequent exploitation under various names and in various combinations among physicians, suggests that this substance be
recognized in the next revision of the U. S. P. as a therapeutic agent in a satisfactory form which physicians could prescribe with the good results that are apparently obtained with the commercial specialties now offered on the market. Combinations of phenolphthalein with cascara, podophyllin, ipecac, nux vomica, etc., are suggested as giving desirable results in most cases.—Proc. N. J. Pharm. Assoc., 1909, 46-47.

**Pyramidon (Dimethylaminoantipyrine)—Error in Valuation-Test of the Codex.** — The French pharmacopoeia states that 0.5 Gm. of dimethylaminoantipyrine dissolved in 50 Cc. of water should, after addition of a few drops of methylorange solution, require 21.75 Cc. of normal sulphuric acid solution to the beginning of the red color. Dr. P. Lemaire points out that there is an evident error in this statement, and that \( \frac{1}{10} \) sulphuric acid is doubtless intended, unless the quantity of pyramidon taken should be 5.0 Gm. Furthermore that with methyl orange as indicator, 0.5 Gm. of pyramidon should require exactly 2.16 Cc. normal sulphuric acid for neutralization.—Pharm. Ztg., lv (1910), No. 38, 385; from Rép. de Pharm., 1910, No. 4.

**GLUCOSIDES AND NEUTRAL PRINCIPLES.**

*Cyanogenetic Glucosides—Classification.*—In concluding their references to the recent numerous researches on the glucosides and enzymes concerned in the production of benzaldehyde and hydrocyanic acid, Schimmel & Co. mention that upon comparing those glucosides known up to the present, which when decomposed yield benzaldehyde and hydrocyanic acid, it will be found (as stated by E. Bourquelot at the VII International Congress for Applied Chemistry) that these bodies may be divided into two classes, viz., those which, when hydrolyzed, form one and those which form two, molecules of glucose:

(a) 2 mol. glucose: amygdalin and *iso*-amygdalin.

(b) 1 mol. glucose: mandelic nitrile glucoside, prulaurasin and sambunigrin.

Taking into account the rotation of the mandelic acid which is formed during decomposition, as well as the products resulting from treatment with baryta, the following table may be drawn up to show graphically the mutual relationships of the above-named glucosides:

<table>

</table>
A hitherto unknown glucoside may therefore be expected, which when isomerized with baryta yields \textit{iso}-amygdalin, when completely hydrolized, \textit{d}-mandelic acid, and when partially hydrolized, sambunigrin.

The isomerization of amygdalin into \textit{iso}-amygdalin indicated in the above table was discovered in 1904 by H. D. Dakin, who obtained the conversion by treatment with diluted alkalies in the cold. Fresh communications by F. Tutin are now available, the upshot of which is that \textit{iso}-amygdalin consists of a mixture of two glucosides, viz., amygdalin and neo-amygdalin. Tutin prepared \textit{iso}-amygdalin from amygdalin by allowing it to stand with highly diluted ammonia. The mass having been evaporated to a very thick syrupy consistency, it was at once acetylated, without previous isolation of the \textit{iso}-amygdalin. The heptaacetylamygdalin, recrystallized from alcohol, had a m. p. of 166° to 167° C. and a spec. rot. of \([\alpha]_0^D -37.6^\circ\) C. (in chloroform). By adding a little alcohol to the crude product of acetylation, diluting the solution with ether, and extracting with water, there was obtained from the ethereal solution a product which crystallized in long, colorless needles and possessed the following constants: m. p. 174° C. (from alcohol), \([\alpha]_0^D -65.6^\circ\) C. (in chloroform), —57.1° C. (in acetic ester). The author calls this body heptaacetyl neo-amygdalin. The new glucoside yields, upon hydrolysis \textit{d}-mandelic acid. —Schimmel's Semi.-An. Rep., Oct., 1909, 22-23.

\textit{Amygdalin—Hydrolysis with Acids.}—Up to the present no investigations had been made with the object of determining the process of the hydrolysis of amygdalin by the use of various acids. It was tacitly assumed that they would all have a decomposing action, and that, as is the case with hydrochloric acid, the glucoside, when treated with diluted acids, would yield, in addition to glucose, hydrocyanic acid and benzaldehyde, and, when concentrated acids were employed, mandelic acid and ammonium chloride. W. Walker and V. K. Krieble have now made investigations, however, which have shown that this supposition is incorrect. They found that when amygdalin was heated for \(1\frac{1}{4}\) hours with moderately strong concentrated sulphuric acid (2 Gm. sulphuric acid to 6 Gm. water) it yielded almost the theoretical quantity of benzaldehyde cyanohydrin, while, when treated with dilute sulphuric acid and heated for 2 hours at 98° C., the decomposition process was found to have only reached the stage of formation of \textit{l}-mandelic nitrile glucoside. Concentrated aqueous oxalic acid solution behaved similarly to diluted hydrochloric acid. But the behavior of trichloroacetic acid was most surprising, this agent having no decomposing effect whatsoever. This is the more remarkable when it is remembered that trichloroacetic acid is almost as highly dissociated as is hydrochloric acid.—Schimmel's Semi-An. Rep., October, 1909, 23; from Journ. Chem. Soc., 95 (1909), 1369.

\textit{Aloe-Emodin—Constitution.}—Aloetic acid is formed by the action of
nitric acid on aloin, and when reduced and the product diazotized and heated with alcohol, it yields aloe-emodin, which is regarded as "trioxy-methyl-anthraquinone. O. A. Oesterle and G. Riat now show that when aletic acid is oxidized by chromic acid, the oxidation-product reduced by means of potassium sulphhydrate and the body so obtained diazotized and heated with alcohol, a substance is obtained of melting-point 232-234° C., which forms an acetate of melting-point 190-191° C.; these melting-points and the analysis of the body show it to be identical with the dioxyanthraquinone which has been previously described under the name chrysazin. This shows that the three hydroxyl groups originally present have been reduced to two, and so supports the formula assigned to aloe-emodin by Robinson and Simonson, in which one hydroxyl is attached to the side-chain. The latter regard alochrysin, to which they attribute aldehyde character, as being intermediate between rhein as a carbon acid and aloe-emodin as an alcohol; but the present authors regard this assumption as incorrect, since one of the authors has demonstrated that the oxidation product of aloin designated as "alochrysin" is in reality a mixture of aloe-emodin and rhein. The authors promise to give further information concerning aloin and rhein in an early communication.—Arch. d. Pharm., 247 (1909, No. 6, 413-417.

Aloins—Character of the Hydrolytic Sugar—Aloinose.—The researches of E. Léger in 1903 (see Proceedings 1903, 969) had indicated that a sugar was produced by the hydrolysis of aloin. It was subsequently found that solutions of barbaloin in alcohol, 90 per cent., were slowly hydrolyzed, becoming syrupy in three years, but still being bitter. A little dilute sulphuric acid was then added, and after another two years and five months the bitter taste had completely disappeared. The syrup was then diluted with water, which precipitated aloemodin. This was filtered out. The filtrate containing the sugar was purified by means of barium carbonate, decolorized with animal charcoal, in the cold, and evaporated to dryness in vacuo. The residue was taken up with absolute alcohol, concentrated in vacuo, and exposed over sulphuric acid. The resulting sugar, alloinose, could not be obtained crystalline; it forms an almost colorless, thick syrup, with a faint saccharine taste, free from bitterness. It reduces Fehling’s reagent, gives the furfural reaction when heated with dilute sulphuric acid and aniline, and gives a violet reaction with hydrochloric acid and orcinol. The violet body thus formed becomes more rapidly insoluble than that given by known pentoses, such as arabinose. On adding a little ether, the precipitated coloring matter is redissolved, tinting the solution violet or wine red. On adding an excess of ether and allowing to separate, the suprernatant ether remains colorless, while the lower layer becomes paler in color and ultimately changes to emerald green. The latter color is very stable, persisting for several days in a closed tube. The precipitated coloring matter gradually becomes darker, and finally is insoluble in ether-
Aloinose is a lævorotatory sugar; its \( a_\infty = -57.3^\circ \) to \( 58.5^\circ \) C.; it gives an osazone crystallizing in long pointed leaflets. Nataloin, when exposed for a year in alcoholic solution to the action of very dilute sulphuric acid, remains almost entirely unaffected. A small amount of sugar is, however, formed, apparently a pentose, like aloinose from barbaloin. It is to be noted that barbaloin, which is dextrorotatory, furnishes aloinose, which is lævorotatory, thus following the rule observed with other glucosides. The isolation of this sugar shows that all formulæ for barbaloin which do not allow for its formation by hydrolysis, such as that put forward by Robinson and Limonsen, are untenable.—Pharm. Journ. and Pharmacist, June 18, 1910, 759; from Journ. de Pharm. et Chim., 1910, 7, 528.

Aloin—Glucosidal Nature.—O. A. Oesterle and G. Riat have determined by their experiments that contrary to the assumption of Léger that aloin belongs to a class of glucosides which are not hydrolyzed by dilute acids, that al’oin may be split up by both alcoholic sulphuric- and alcoholic hydrochloric-acid into aloe-emodin and a sugar, the precise nature of which has not yet been determined; and, furthermore, that by either method the aloe-emodin is accompanied by an uncrystallizable body, soluble in alkalies with a red color. Of the two methods, the hydrolysis of the aloin with alcoholic hydrochloric acid is preferable to that with alcoholic sulphuric acid. The observation is of importance for reliably establishing the chemical formula for aloin.—Schweiz. Wschr. f. Chem. u. Pharm., xlviii (1909), No. 47, 717-721.

Commercial Apiols—Physiological Action.—The fact that the crystalline apiol, which has been made official in the French Pharmacopoeia, is practically unobtainable, has led L. Lutz to compare its physiological action with other kinds, and with essential oil of parsley. It is found that in intravenous injections all kinds of commercial liquid apiols and essential oil of parsley have almost the same toxic power; all act as vaso-dilators, and lessen the arterial blood pressure. Slowing of the cardiac contractions and an augmentation of their amplitude occurs, except with yellow apiol, which lessens the latter. The toxic dose of all is, approximately 5 mls for a dog of 9 to 12 kilos. With crystalline apiol it is above 5 Gm. The diminution of the arterial pressure is much less prolonged after giving crystalline apiol than after the other kinds. White apiolin is the most active; and the essential oil is the most regular in its action.—Pharm. Journ. and Pharmacist, May 21, 1910, 646: from Bull. Sci. Pharm., 17 (1910), 7.

Crystalline Apiol—Protest Against Inclusion in the French Pharmacopoeia.—Mathurin points out that nothing is definitely known of the method of preparation of “crystalline apiol” (proposed for inclusion in the French Pharmacopoeia), of its posology, or of its physiological action; and it is not a constituent occurring in any quantity in French parsley
seed. Although it is prepared in Germany it is not official in the German or any other current pharmacopoeia. Liquid apiol was at one time official in Belgium, but has since been deleted from the official work. The plea for its introduction, that being crystalline, it is less easily adulterated, is untenable, since from its low melting-point, 30° C., it is liquid in warm weather. It cannot be manipulated in a natural condition and has to be diluted with oil or with an excipient. It is stated that the inert residual fat which is a by-product in the manufacture of active liquid apiol has been sold as "crystalline apiol" when dissolved in oil and enclosed in capsules. Not only so, crystalline apiol is said not to be procurable in commercial quantities.—Pharm. Journ. and Pharmacist, July 17, 1909, 73; from Bull. Comm. (L'Union Pharm.), 37 (1909), 285.

Aucubin—Distribution in the Genus Aucuba.—The glucoside aucubin, first isolated by Bourquelot and Herissey in 1902, from the seeds of Aucuba japonica, is found by C. Lebas to be widely distributed, having been isolated by the author from every species of the genus examined. The seeds of each species not being available in sufficient quantity, the entire plant was treated in each case. The following approximate percentages of crude aucubin were obtained from the species indicated: Aucuba japonica, var. elegantissima, 0.31; var. latimaculata, 1.96; var. longisolia, 1.44; var. punctata, 1.60; var. salicifolia, 1.51; var. viridis, 1.64 per cent.—Pharm. Journ. and Pharmacist, Dec. 4, 1909, 701; from Journ. de Pharm. et Chim., 30 (1909), 390.

Cubebinic Ether—A Derivative of Cubebin.—Mameli finds that when a solution of cubebin in glacial acetic acid is titrated with a dehydrating body, cubebinic ether, C_{20}H_{30}O_{6}, is formed. The best dehydrating agent for this purpose is hydriodic acid, specific gravity 1.7. After the addition of this (in quantities depending on the purity of the cubebin used), the mixture is shaken for several hours, then poured into twelve times its volume of water. A bulky white precipitate forms, and, after standing for several days, this is collected and crystallized from hot diluted alcohol. In this way it is obtained in form of handsome, white, colorless needles, having a m. p. of 78° C. and an opt. rot. (in chloroform) of +23.04°. The alcohol—

Cubennol, (CH_{2}-O_{2}-C_{6}H_{15})_{2}-C_{6}H_{5}OH, is obtained by reducing this ether with alcohol and sodium. After the reaction, the mixture is precipitated with water, and the cubennol crystallized—first from alcohol, and then from a mixture of petroleum ether and benzene. The yield is theoretical. Cubennol forms long, white needles, having a m. p. of 92° C. and an opt. rot. (in chloroform) of +34.81°.—Pharm. Journ. and Pharmacist, Sept. 25, 1909, 393; from Gazz. Chim. ital., through Journ. de Pharm. et Chim., 30 (1909), 220.

Gentiopticrin.—Occurrence in Chlora perfoliata, which see under "Materia Medica."
Oleuropein—Confirmation as a Constituent of Olive Trees.—E. Bourquelot and J. Vintilesso confirm their previous statement (see Proceedings, 1909, 392) as to the presence of oleuropein in the fresh organs of the olive tree, and specially in fresh green olives. The biological method of successive hydrolysis, with the ferment invertin and emulsin, indicates that by far the greater amount occurs in the young green fruits before the hardening of the stones. About one-third of the oleuropein originally present in these disappears during the process of drying; in the olives of commerce no trace remains. The sugar formed under the influence of emulsin has been isolated, and proved to be glucose. The failure of Power and Tutin to confirm the existence of the glucoside is attributed in the main to the fact that they employed the alcoholic extract of dried olive leaves as the material for investigation.—Pharm. Journ. and Pharmacist, May 7, 1910, 571; from Journ. de Pharm. et Chim., t (1910), 292.

Vanillin—New Synthesis Method.—Guyot and Gry report on a new synthesis of vanillin. They condense guaiacol for a fortnight in cold glacial acetic acid solution, in the presence of zinc chloride, with mesoxalic ester or with the α, β-diketocarboxylic esters, of which the constitution is similar, such as acetyl- or benzoyl-glyoxylic ester, afterwards heating it for several hours to about 50° C. After diluting the solution with water, shaking with ether, and washing the ether with soda solution, any unchanged guaiacol is removed by means of steam and the condensation product is recovered in the crystalline form. By oxidation with acetate of copper at 80° C. these compounds can be quantitatively converted into vanilloyl-carboxylic acid, but, as regards the mesoxalic ester derivative, this can be obtained only after saponification and boiling with copper chloride. From the acid—referred to, dimethyl-p-toluïdaz, at 170° C., splits off almost quantitatively carbon dioxide and, in contradistinction to other vanillin-processes, the result is a very pale vanillin which is free from isomerides and from resinous substances.—Schimmel's Semi.-An. Rep., April, 1910, 150; from Compt. rend., 149 (1909), 928.

Strophanthin—Influence of Method of Administration on its Toxicity.—A series of physiological experiments, by J. Pédebidon, with both crystalline and amorphous strophanthins show that in all cases they are from twenty to thirty times more toxic when administered by muscular injection than when given by the mouth, and from forty-three to eighty-six times more toxic than the latter when the injection is intravenous. Consequently the last-named method of administration should never be employed. The most safe and certain method of exhibiting strophanthin is by the mouth. Catillon showed in 1889 that amorphous strophanthin from Strophanthus hispidus is two and a half times less toxic than the crystalline glucoside from S. Kombé.—Pharm. Journ. and Pharmacist, Sept. 4, 1909, 319; from Compt. rend., 149 (1909), 306.
COLORING MATTERS.

Artificial Coloring Matter in Galenicals—Detection by Means of Hydrogen Dioxide.—Miss M. Paul has observed that when galenical preparations, such as syrups, tinctures, etc., prepared from vegetable drugs, are subjected to the action of hydrogen dioxide for a sufficient time (up to 48 hours), complete decoloration results, with the exception of those containing chlorophyll, which must be shaken out with benzin. This observation leads her to recommend the reaction for the detection of artificial coloring matter, such as fuchsin, Bordeaux red, Bismarck brown, etc., which are not decolorized by $\text{H}_2\text{O}_2$, the method being of particular value for their detection in fruit juices and syrups.—Pharm. Ztg., lv (1910), No. 28, 283; from Journ. de Pharm. et Chim., 1910, No. 6.

Bixin—Chemical Constitution.—According to J. F. B. Van Hasselt, bixin, the red dyestuff of annatto (Bixa orellana), has the composition $\text{C}_2\text{H}_9\text{O}_5$; it contains one hydroxyl and one methoxyl group. It melts at 180° C., and when heated in a current of hydrogen at 200° C. evolves one molecular proportion of $m$-xylene, leaving a colorless residue. By the action of dilute potassium hydroxide solution on bixin, there are formed, first, potassium bixinate, $\text{C}_2\text{H}_9\text{O}_4(\text{OK})(\text{OCH}_3)$, and then dipotassium norbixinate, $\text{C}_2\text{H}_9\text{O}_5(\text{OK})_2$. The latter, when treated with dilute acids yields norbixin, $\text{C}_2\text{H}_9\text{O}_5(\text{OH})_2$, a bright red crystalline substance, which decomposes at 240° C., and can be converted into bixin by partial methylation. By the action of zinc dust and glacial acetic acid bixin and its derivatives yield dihydro-compounds; while by the action of bromine, white, amorphous, unstable compounds containing ten atoms of bromine are produced.—Pharm. Journ., Oct. 30, 1909, 537; from Chem. Weekblad., 6 (1909), 480, through Journ. Soc. Chem. Ind., Sept. 30, 1909, 975.

Chlorophyll—Conditions for its Formation.—In continuation of his studies relating to the conditions for chlorophyll formation, B. L. Issatchenko states that a low temperature (—8° C.) does not prevent the formation of chlorophyll, and that it is formed in plants as quickly at a low temperature as at a high one, the formation of the pigment depending exclusively on the strength and duration of the light. According to other results obtained, the formation of chlorophyll continues in the presence of the vapor of formaldehyde or chloroform.—Pharm. Journ. and Pharmacist, Dec. 25, 1909, 795; from Bull. du Jardin Imper. Botanique, St. Peters burg, ix, Part v.

Chlorophyll—Comparative Examination in Different Plants.—Richard Willstätter, F. Hocheder and E. Hug have made a series of comparative examinations of the chlorophyll in different plants. The method adopted is based on the separation of the pure chlorophyll in the form of its hydrolytic product, as completely as possible, and its subsequent quantitative saponification, leading thus to the phyto-number, indicating the per-
centage of phytol in the phaeophytin. This phyto-number was determined by the authors in 70 species embraced by 36 families, and proved the extraordinary distribution of phytol—the uncrystallizable chlorophyll—in plants, the presence of crystallizable chlorophyll having been determined only in five of the plants under examination. Regarding the

Reduction of Chlorophyll by Alkalies, the authors find that the first product resulting from the alcoholic saponification to be chlorophyllin; this is then converted into the blue glaucophyllin, then into rhodophyllin and, finally, into two other red compounds, which the authors name respectively pyrophyllin and phyllophyllin. The nature of all of these compounds is comprehensively described and their probable chemical formulas are suggested.—Pharm. Ztg., iv (1910), No. 20, 204; from Chem. Ztg., 1910, No. 13.

Coloring Matter of Cotton Flowers—Glycoside Nature and Description.—According to A. G. Perkin, the alcoholic extract of Egyptian cotton blossoms deposits during evaporation an orange-brown precipitate of glucosidal nature. The aqueous solution of this precipitate produces with lead acetate a red precipitate, which when decomposed by hydrogen sulphide and treated with hot water yields a yellow crystalline powder consisting of a mixture of two glucosidal bodies, one of them a new glucoside of the formula C_{21}H_{20}O_{12}, which the author has named Quercimeritin.—This forms yellow tabular crystals which are fairly soluble in hot water, but insoluble in cold water. It imparts to wool prepared with a suitable mordant a series of color tints, almost identical with those obtainable with quercetin and is thereby distinguished from both quercitrin and rutin. The second glucoside obtained from the crystalline mixture has been named Gossypetrin.—It has the composition C_{21}H_{20}O_{13}, and occurs in form of pale orange-yellow needles.—Pharm. Ztg., iv (1910), No. 30, 304, from N. Chem. Zentralbl., 1910, No. 8.

Kaempherol—A Hydrolytic Product of Robinin.—N. Walliaschkho has made a comprehensive investigation of the glucoside robinin prepared from the flowers of Robinia pseudacacia. He has determined the formula C_{20}H_{40}O_{19} for the pure, carefully dried substance, and that by the action of mineral acids on its aqueous solutions robinin is hydrolyzed with formation of 1 mol. galactose, 2 mol. rhamnose and 1 mol. of a yellow coloring matter, according to the equation: C_{20}H_{40}O_{19} + 3H_2O = C_6H_{12}O_6 + 2C_6H_{12}O_3 + C_{15}H_{19}O_6. This coloring matter, which in a previous investigation (see Proceedings, 1905, 830) had been named "robingenin" by the author, was subsequently regarded by Perkin as being identical with "kaempherol"—an assumption which by Walliaschkho's present investigation is completely confirmed.—Arch. d. Pharm., 247 (1909), No. 6, 447-461.

Methylene Blue—Prevention of Blue-colored Urine when Used In-
ternally.—H. Ménigault states that the persistent blue coloration of the urine voided by patients treated with methylene blue by the mouth may be prevented by the simultaneous use of iodine. He finds that if during the treatment, tincture of iodine is applied to any part of the body, and especially the spinal column, the urine emitted is no longer colored. On heating a little of this urine in a test-tube, the liquid at once becomes blue, the reason being due to the iodine having been driven off by the heat, and thus thrown out of reaction with the methylene blue. The experiment is claimed as a means of detecting the cutaneous absorption of iodine in alcoholic solution, a question which has frequently been doubted.

Microscopic Color-Stains—Removal from the Fingers.—In microscopic manipulations with color-stains it is at times unavoidable to stain the fingers. Dr. Ernest Richter mentions in the following a number of color solutions used in microscopic work and the fluids that he has found most useful in removing the stains produced by them:

For carbolfuchsin, carbolthionin, cresyl violet (genuine), Giemsas’ solution, Leishman’s blood-coloring matter, Leffler’s methylene blue solution, orcein-water blue solution, and polychrom. methylene blue solution:

Use Spiritus Saponatus.
For carbolgentian violet:
Use Absolute Alcohol.
For Ehrlich’s triacid solution, Esbach’s reagent, and hæmatoxylin—
Delafiel solution:
Use Hydrogen Dioxide (3 per cent.) and Ammonia Water, equal parts.
—Apoth Ztg., xxv (1910), No. 7, 55.

ALBUMEN.

ALBUMINOIDs.

(Including Animal Products).

Albumen—Color Reaction.—C. Reichard has comprehensively studied the color reactions obtainable with albumen and describes the action of acids and bases upon the dry powdered egg albumen, which, after soaking in water, gives very handsome color reactions in many instances. By the action of various metallic salts, particularly with salts of copper, he has also obtained noteworthy reactions, and interesting reactions were also obtained with vanillin and hydrochloric acid, with urea and sulphuric acid, and with phenylhydrazin, &c.—Pharm. Zty., lv (1910), No. 16, 158–160.

Albumen—Determination in Urine.—T. Morikawa recommends the following simple method for determining the presence of albumen in urine:

—The urine is diluted with two or three times its volume of water, and 5 Cc. of the mixture is poured into a test tube, followed by 3 Cc. of solution
of potassium iodide and 2 drops of 36 per cent. acetic acid. In presence of 0.01–0.02 per cent. of albumen a white ring will develop at once at the zone of contact of the two layers, while with 0.005 per cent. the ring manifests itself in about 2 minutes.—Pharm. Ztg., liv (1909), No. 63, 612; from Ztschr. d. Allg. Oesterr. Ap.-Ver. 1909, No. 29.

**Albumen—Modification of Esbach's Method of Estimation in Urine.**—Kwilecki recommends the following modification of Esbach's method of estimating albumen in urine, whereby the time for carrying out the test is shortened from the entire day usually required to from two to at most six minutes, depending on the amount of albumen present. The apparatus is filled to the mark with the urine—which must be acid: 10 drops of 10 per cent. solution of ferric chloride are added, mixture is effected by gentle agitation, and Esbach's solution is then added to the required mark. The container is then well corked and the contents mixed by shaking, not too violently. Meanwhile water having been heated to about 72° C., in a vessel specially constructed for the container, the latter is introduced after removing the flame, observing that the water shall reach about 1 Cm. higher than the reacting mixture. The latter clarifies rapidly; the albumen subsides, and its amount may be read off within the short period above mentioned.—Pharm. Ztg., liv (1909), No. 55, 538; from Münch. Med. Wschr., 1909, No. 26.

**Albumen—Simple and Reliable Method of Determination in Urine.**—Having in numerous instances observed that the usual tests for albumen in urine may be misleading and under certain conditions yield very different results, Dr. Fr. Engel has made a comprehensive series of experiments which lead him to recommend, as one of the most convenient and reliable methods, the well-known method of boiling the urine, with the subsequent addition of diluted acetic acid—the urine being heated in the upper part of the test-tube. For confirmation, if deemed necessary, the acetic acid-ferrocyanide test may also be made; but all tests depending on the preliminary addition of acids should be rejected.—Pharm. Ztg., liv (1909), No. 98, 968; from Deut. Med. Wschr., 1909, No. 47.

**Albumen—Two New Reactions.**—Y. Oguro describes two new reactions for albumen in urine which, in spite of the already large number that have been proposed, deserve attention. The first is obtained by acidulating 5 Cc. of the urine with a few drops of acetic acid, adding 1 Cc. tincture of iodine, and following this with the addition, drop by drop, of saturated solution of sodium bisulphite until the brown color of the solution disappears. In the presence of albumen the decolorized mixture exhibits a white turbidity.—For the second reaction tincture of iodine decolorized with exactly the necessary quantity of saturated solution of bisulphite is used. To 6 Cc. of the clear urine, strongly acidulated with acetic acid, 2 Cc. of this reagent are added. In the presence of albumen, white pre-
cipitate or turbidity is produced immediately or after a short while. Both reactions are characteristic for albumen, and are available for dilutions of 1:120000.—Pharm. Ztg., lv (1910), No. 43, 436; from Merck’s Annual Rep., April, 1910.

**Human Blood—Simple Method of Differentiating.**—T. Tiorkowsky differentiates human blood from that of the lower animals by the following simple method:—Into a test-tube, about 6 Cms. long and 8 Mm. in diameter, 1 Cc. of hydrocele liquid or human blood serum (the former is preferable) is introduced. In another vessel, a drop of the fresh blood to be examined is diluted with 10 to 50 drops of water. This latter liquid is carefully poured into the test-tube containing the serous liquid in such a way as to form a layer. If the blood is of human origin there is formed in about half-an-hour a faintly red-colored precipitate of coagulated blood, while the supernatant liquid remains clear. Operating in the same way with the blood of any of the lower animals, no precipitate is formed, and the liquid is colored red. Dry blood is first dissolved in physiological salt solution before applying the test.—Pharm. Journ. and Pharmacist, Aug. 14, 1909, 240; from Gaz. Médic. de Paris, June 1, 1909, 11.

**Milk—Home Pasteurization.**—L. A. Rogers makes some practical suggestions regarding the home pasteurization of milk, which may be done with the simplest outfit. Milk is most conveniently pasteurized in the bottles in which it is delivered. To do this use a small pail with a perforated false bottom. An inverted pie tin with a few holes punched in it will answer this purpose. This will raise the bottles from the bottom of the pail, thus allowing a free circulation of water and preventing bumping of the bottles. Punch a hole through the cap of one of the bottles and insert a thermometer. The ordinary floating type of thermometer is likely to be inaccurate, and if possible a good thermometer with the scale etched on the glass should be used. Set the bottles of milk in the pail and fill the pail with water nearly to the level of the milk. Put the pail on the stove or over a gas flame and heat it until the thermometer in the milk shows not less than 150° nor more than 155° F. The bottles should then be removed from the water and allowed to stand from twenty to thirty minutes. The temperature will fall slowly, but may be held more uniformly by covering the bottles with a towel. The punctured cap should be replaced with a new one, or the bottle should be covered with an inverted cup.

After the milk has been held as directed it should be cooled as quickly and as much as possible by setting in water. To avoid danger of breaking the bottle by too sudden change of temperature, this water should be warm at first. Replace the warm water slowly with cold water. After cooling, milk should in all cases be held at the lowest available temperature.—Druggists’ Circular, Nov., 1909.

**Milk—Decomposition of Carbonophosphates by Pasteurization.**—Ac-
cording to the investigations of A. Barillé, milk contains an unstable cal-
cium carbonophosphate, which is decomposed by the process of Pasteur-
izing with the precipitation of calcium carbonate and dicalcic phosphate
and liberation of carbonic acid gas—that is, the natural soluble phosphate
compound is rendered insoluble. Although the amount of calcium phos-
phate thus rendered less easily assimilable in Pasteurized milk is small, and
probably negligible from the point of view of alimentation of adults, this
cannot be the case in milk used for the artificial rearing of infants. It is
suggested that possibly sterilization by means of light might be substituted
for Pasteurization for such milks. This treatment does not affect the cal-
cium carbonophosphate, and the milk thus sterilized appears to be iden-
tical, in all respects, to “living” milk.—Pharm. Journ. and Pharmacist,
Sept. 18, 1909, 365; from Compt rend., 149 (1909), 356.

Milk and Butter—Rapid Detection of Boric Acid.—E. Gauvry proposes
a method for detecting boric acid in milk and in butter, which is based
on the deep red coloration given by boric acid with turmeric in presence
of oxalic acid. About 10 Gms. of butter is vigorously shaken in a suit-
able vessel with 20 to 25 Cc. of water sufficiently hot to melt the butter;
when the fatty layer separates the aqueous portion is filtered through a
dry filter into a centrifuge tube; to the filtrate, 7 or 8 drops of baryta
water and about 10 Cc. of alcohol are added. The whole is allowed to
stand for several minutes, and then centrifugated; the liquid is decanted
and 1 Cc. of a hot concentrated solution of oxalic acid is poured on to
the precipitate remaining in the bottom of the tube; the barium oxalate
dissolves in the excess of oxalic acid, and is re-precipitated by the addi-
tion of a sufficient quantity of alcohol. The liquid is again centrifugated,
the clear portion decanted into a white porcelain capsule evaporated on a
water-bath, not above 85° C., after having added a few drops of tincture
of turmeric. A red coloration of the residue indicates boric acid, and the
reaction will detect 0.1 Mgm. of the acid with ease. The coloration varies
from rose to vivid red, and its intensity is proportional to the amount
of the acid in the butter. In the absence of borates, the coloration obtained
is pale yellow. For milk the ash is used; it is taken up with a drop of
hydrochloric acid and a few Cc. of tepid water. This is treated with
baryta water and the process carried out as described.—Pharm. Journ.
15, 1910, 14.

Soured Milk—Preparation by the Pharmacist.—The therapeutic appli-
cation for “soured milk” has created a new demand upon the pharmacist,
which Ernest C. Cripps illuminates by some pertinent remarks. He says
there are apparently still some pharmacists who are not alive to the possi-
bilities of business due to the wave of enthusiasm spreading over the coun-
try, principally caused by the medical profession ordering for indigestion
and other stomach and intestinal troubles what is popularly known as "soured milk." It is quite possible for many to make "soured milk" and supply it regularly to those requiring it. The public certainly prefer it made by the pharmacist than by the dairyman, for the process needs most scrupulous cleanliness, and also a temperature that does not vary more than a few degrees. Both of these requirements can be met by the pharmacist. The apparatus need not cost much. A few pots and saucepans, and a source of heat that will maintain a constant low temperature—these can be improvised by any ingenious worker. The necessity for the most rigid precautions as to cleanliness must, of course, be insisted upon. All utensils should be either boiled or dipped into boiling water, and allowed to drain dry, as if wiped by a duster, no matter how clean it may appear, germs are introduced. The bottles in which the finished product is sent out to customers, must be filled fitted with a good cork or rubber lining to the tin cap. Incidentally, a very good demand is arising for the many lactic acid producing tablets, liquid cultures, "machines" and apparatus for home production of "soured milk." No great stock of these need be carried, but the pharmacist should be in readiness to supply them. It is also noted by the author that properly prepared "soured milk" should contain 2 per cent. of lactic acid and should produce a distinct acid reaction with litmus paper.—Pharm. Journ. and Pharmacist, Jan. 22, 1910, 78.

Soured Milk—Production with Preparations of Lactic Acid Baccilli.—E. Quant contributes some observations on the commercial preparations of lactic acid bacilli. Working on two English and two Continental brands of tablets and a milk culture, he shows that lactose has no influence on the acid production, and considers that the disappointments which have been expressed in the preparation of sour milk are due (1) to employing insufficient bacterial substance, (2) to inefficient temperature. The night lights of some of the popular apparatus have been found to give a temperature varying 15° F. The author recommends the use of a moist culture to obtain the best results, and cultivating for at least four hours between 105° and 110° F., the growth of adventitious organisms being thereby inhibited, and an amount of lactic acid quickly produced to retard their subsequent development.—Pharm. Journ. and Pharmacist, Jan. 29, 1910, 109; from Brit. Med. Journ., Dec. 18, 1909, 1736.

T. D. Luke confirms most of the observations in Quant's paper above quoted, and now adopts milk cultures for the

Preparation of Soured Milk.—He finds that with a temperature of 108° to 110° F., a very pleasant curdled milk is obtained in about five hours. He replaces the simple tin apparatus and night-light by a wooden box, about 2 ft. by 2 ft. by 3 ft., lined with asbestos and fitted with a metal tray, sliding out, and placed over two 8-candlepower electric lamps, with the thermometer passed through the top of the box, as in a bacteriological oven. The front side of the box falls down by means of a hinge,
allowing the removal of the metal tray, which will hold some thirty glasses of milk. The front is fitted with a little sliding door about 2 in. by 8 in., and by means of this a supply of cooler air is regulated to keep the box from getting too hot.—Ibid.; from Brit. Med. Journ., Jan. 1, 1910, 52.

Buttermilk—Preparation from Sweet Milk by Means of Lactic Acid Bacteria.—F. W. Nitardy gives a method for preparing lactic acid cultures, and by the aid of these “buttermilk” from sweet milk, in “Proceedings,” 1909, 1138–1139.

Yoghurt—Preparation.—Henneberg comprehensively discusses the nature of the ferment concerned in the preparation of yoghurt, and recommends a method for its preparation. Operating with pure cultures obtained from original Oriental yoghurt, he finds them to consist of three milk ferment: Bacillus bulgaricus, Streptococcus, and Bacterium lactici, acidi. The first of these, by frequent transmission, suppresses the other two in the preparation of yoghurt. Both pure cultures and ordinary cultures can be supplied (by the “Institut für Gärungsgewerbe, Berlin, ?) the latter, if used without delay, being practically quite as efficient as the pure cultures. The cultures are added to sterilized milk at 45° C.; or a little of the previously prepared yoghurt (which has been preserved at from 30°–40° C.) is added to the milk. As soon as coagulation is completed (usually in 4 to 6 hours) the acidulous milk (yoghurt) is set aside in the cold, ready for use.—Pharm. Ztg., liv (1909), No. 102, 1005; from Ztschr. Spir. Ind., 1909, 489.

Powdered Milk—A Useful Commercial Product.—Prof. Joseph Feil, in a paper entitled “The Drug Store Cow,” speaks interestingly on the subject of milk, evaporated milk, powdered milk and milk foods. In regard to powdered milk he says that this is a recent addition to milk products, mostly made from skim or “centrifuged” milk, with the addition of variable quantities of butter fat. It is made to a large extent, by two patented processes. One method is to spray the milk in a very fine stream, under pressure, into a large room having a current of dried air passing through it: the other method involves the use of a revolving cylinder, heated to about 180° F. by steam, on which the milk is spread in a thin stream, and in twelve seconds or half a revolution is so well dried that it contains only one per cent. of water. It is mechanically scraped off and then immediately powdered. This product is used extensively by bakers, but would seem to be useful in pharmacy for preparing emulsions, infants’ and invalid’s food, malted milk, etc. The average composition of the powdered milk at present on the market is as follows:

<table>
<thead>

</table>
The author also makes some interesting observations respecting the so-called "Butter-Milk Tablets" which, as supplied by the manufacturers and used according to their directions yield anything but the real Metchnikoff product.—Proc. Ohio State Pharm. Assoc., 1909, 56-59.

_Emulsin-Hydrolysis—Retarding Action of Certain Substances.—A. Fichtenholz finds that gallic acid, hydroquinone, and tannin all exercise a retarding influence on the hydrolysis of glucosides by emulsin; but this influence, which in some cases goes so far as absolutely arresting the action of the ferment, varies in the different glucosides. _Hydroquinone_ markedly retards the action of emulsin on arbutin, but has only a relatively slight retarding action on the emulsin-hydrolysis of salicin, gentiopicrin, and amygdalin. _Gallic acid_ entirely stops the emulsin-hydrolysis of arbutin, and greatly retards that of aucubin, while with other glucosides it is variable and less marked. _Tannin_ retards but does not absolutely arrest the emulsin-hydrolysis of arbutin; it retards the action of emulsin on other glucosides, but not precisely in the same degree as gallic acid.—Pharm. Journ. and Pharmacist, Sept. 25, 1909, 393; from Journ. de Pharm. et Chim., 30 (1909), 204.

_Salicase—An Enzyme of Salix Purpurea._—T. Weevers has previously studied the glucoside salicin present in the twigs of _Salix purpurea_ as a reserve product, with reference to the physiological significance of some glucosides, and had observed that when the shoots start growing the salicin gives place to saligenin, and this apparently to catechol. He now reports the discovery of the enzyme, _salicase_, which decomposes salicin. Further, he identifies two oxidation ferments, which act upon saligenin and catechol respectively. These and other results lead to the following argument: During the summer, salicin is formed in the leaves by day, but is decomposed by night, and the glucose is transported to the cortex; each day the catechol combines with more glucose to form salicin. In the autumn the process ceases, because the cortex contains as much salicin as the leaves. These conclusions agree with the hypothesis that benzene derivatives combine with carbohydrates to form substances which diffuse with difficulty, and that serve to keep the sugar stored in the tissues.—Pharm. Journ. and Pharmacist, Febr. 12, 1910, 173; from Recueil Trauvaur botaniques Neerlandais, Vol. V.

_Digestive Ferments—Use in Medicine._—Dr. C. G. Stockton says that different foods require for their hydrolysis the attack of different sorts of ferments, and the organism is provided with a variety of these secretions. The several ferments operate unfavorably on each other. Thus, ptyalin acts for the most part in the stomach previous to the free secretion of acid gastric juice, which inhibits the ptyalin; and the gastric ferments, in their acid medium, are in turn made inactive through the secretions entering the duodenum. It will thus be seen that the administration of digestive
ferments as medicaments is open to physiological objections. Ptyalin, certain pancreatic preparations, and some of the diastases are possessed of a certain amount of power in the conversion of starch into maltose and dextrin when thoroughly mixed with carbohydrate food at the time of ingestion. Practically the activity of all these substances ends as soon as the gastric secretion has become mixed with the stomach contents. The author is unable to satisfy himself that intestinal digestion is improved by the administration of any ferments whatever. In the case of malt extracts and other forms of diatase, it is difficult to determine how much improvement in digestion is subjective, and how much of it owing to the extractive matter, bitter, or aromatic substances which may accompany the ferments in question. On the whole it must be concluded that the question of the administration of digestive ferments in medicine is complicated and is rendered the more uncertain by lack of precise knowledge as to what becomes of them in the digestive canal. There can be no question that a large number of preparations which have been placed on the market are practically inert. Many combinations that are widely advertised, and presumably largely prescribed, are self-destructive, provided they are made as represented. That is to say, the various elixirs, etc., said to contain pepsin, pancreatin, hydrochloric acid, lactic acid, vegetable diastase, etc., are not only unphysiologic in theory, but by careful analysis made by the Council on Pharmacy and Chemistry of the American Medical Association have been shown to be practically worthless so far as digestive activity is concerned. Journ. Amer. Med. Assoc., Nov. 20, 1909, 1703.

Papain—Digestive Properties.—The experiments of Pozerski show that papain digests albumin with extraordinary rapidity at high temperatures; the maximum action appears to occur between 80° and 95° C. It is only necessary to bring to a boil a mixture of ovalbumin or serum and a suitable quantity of papain to transform most of the albuminoids into albumoses or peptone. Papain has the special property of attacking albuminoids at the moment when they are losing their natural properties. Egg albumin and serum are progressively attenuated, at ordinary temperatures, by papain, but are not actually digested until heated. Animal tissues in a natural condition and vegetable albuminoids undergo rapid digestion at a high temperature.—Pharm. Journ. and Pharmacist, July 24, 1909, 105; from Ann. Inst. Pasteur, through B. M. I., 1909, 2, 3.

Pepsin—Inefficiency of the G. P. Method of Valuation.—Dr. Kehler calls attention to some defects in the German pharmacopoeial method for the examination and valuation of pepsin. He finds that both the temperature (45° C.) and the time of exposure (one hour) directed in the G. P. are too low, and speaks commendably of the requirements of the U. S. P. in these respects, viz., a temperature of 52° C. and an exposure to that temperature for 2½ hours, which he finds experimentally to yield satisfac-
tory and reliable results. The direction of the U. S. P. also, to immediately cool down the reacting mixture by the addition of cold water at the end of the time limit, is recommended. Regarding the character and frequency of shaking the reacting mixture, he considers violent or frequent shaking to be a disadvantage. Gentle rotation of the mixture at intervals of a quarter of an hour is regarded as being most efficient.—Apoth. Ztg., xxv (1910), No. 27, 230.

**Pepsin—Stability of the Peptonizing Power of the Liquid Preparations.**—A. Petit and A. L. Petit report the results of experiments extending over a period of more than six years, undertaken for the purpose of ascertaining the changes in the peptonizing power of liquid preparations of pepsin—such as elixirs, wares, etc.—by prolonged keeping. These results, in contradiction to those recorded by Thibault in 1881, prove that these preparations retain practically their full digestive power for years, and that, while here and there it was possible to determine a diminution in the peptonizing effect, this was so slight as to be practically negligible. The authors account for the unfavorable results of Thibault, on the ground that in his experiment the hydrochloric acid solution of pepsin was heated for one hour at 50° C. before adding the fibrin, which, in the experience of the authors wholly, or at least partially, destroys the peptonizing power of the pepsin.—Pharm. Ztg., lv (1910), No. 19, 189; from Journ. d. Pharm. et Chim., 1910, No. 4.

**Pepsin and Pancreatin—Their Chemistry and Uses.** These are ably discussed in a paper contributed by Bernard Sacks, M.D., at the Los Angeles meeting, which appears in the "Proceedings," 1909, 1122-1131.

**Pancreatic Ferments—Action of Heat.**—According to E. Choay, the pancreatic diastases, in a dry condition, may be heated to 80° or 100° C. for one or two hours without their diastasic power being materially affected. At a temperature of 120° C., however, the proteolytic, amylyolytic, and steaptasic ferments are paralyzed, the amount of inhibiting action being directly proportional to the period of exposure. In the moist state these ferments are very sensitive to the action of heat, even exposure to 40° or 50° C. in a partial vacuum, such as is employed in the commercial preparation of dry pancreatic preparations, being sufficient to reduce the activity of the amylyolytic diastase by 75 per cent., and that of the steaptasic ferment by 50 per cent.—Pharm. Journ. and Pharmacist, Febr. 26, 1910, 238; from Journ. de Pharm. et Chim., 1910, 1, 20.

**Gelatin—Color Reaction.**—R. E. Liesegang finds that if a mixture composed of 1 Cc. of 10 per cent. cupric chloride solution and 14 Cc. of 40 per cent. K₂PO₄ solution is added to a 10 per cent. solution of gelatin, the jelly and the liquid assume after 24 hours a deep violet color, whilst the green precipitate of cupric phosphate initially formed gradually diminishes. —Pharm. Ztg., lv (1910), No. 38, 283; from N. Chem. Zentral-Bl., 1910, No. 8.
Gelatin—Superficial Impurities.—In the course of some practical observations on the commercial forms of gelatins and their uses. J. A. Forret directs attention to extraneous impurities derived from the netting on which sheet gelatin is dried. These sheets bear the markings of the netting which in some brands are more or less covered with short lengths of very fine fibers, indicating that the netting used for drying the sheets had been made of rope or cord; while in others the markings are free from adherent matter, the sheets having apparently been dried on wire netting. While for most purposes the presence of a small proportion of innocuous matter, such as the fine fibers referred to, is negligible, when purity and the highest brilliancy in the finished articles are required, gelatin ought always to be washed before it is used.—Pharm. Journ. and Pharmacist, March 5, 1910, 292.

Commercial Clavin—Composition.—D. V. Vanslyke has examined a sample of Vahlen’s commercial clavin. It contained 36 per cent. of ash, chiefly as phosphates of the fixed alkalies, and when purified by precipitation and recrystallization it yielded 55.5 per cent. of ash-free clavin. It proved to be a mixture of leucin, isoleucin, and valin, the respective percentages being 39.1, 22.3, and 37.1. A study of the pharmacological effects of these individual amino-acids is contemplated, in order to determine whether any of them has the specific action of causing contraction of the uterus, as claimed for clavin by Vahlen.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 671; from Journ. Pharmacol. and Experim. Therap., Aug., 1909, 265.

Lecithin—Estimation of Purity.—A simple method of estimating the purity consists according to Mario Morigi in emulsifying the sample with water. A yellowish emulsion indicates impurity, due mainly to fat. A translucent sample indicates the presence of excessive solvent remaining from its preparation. Phosphates and glycerophosphates are frequent impurities. The relative proportions of P to N are about those of their atomic weights: 31 to 14. A material deviation from this proportion must therefore be regarded as due to impurity.—Pharm. Ztg., lv (1910), No. 11, 108; from Chem. Z-Bl., 1909, No. 26.

Nucleinic Acid—Properties.—F. Sauerland has prepared and examined sodium nucleinate from calves-thymus and free nucleinic acid from herings’ sperm and found by qualitative and quantitative tests only minute impurities in the products consisting of 0.02 to 0.03 per cent. of Fe, from which he concludes that pure nucleinic acid must be free from iron. The same result was obtained with a pancreas nucleoproteid obtained by Hammarsten’s method.—Pharm. Ztg., lv (1910), No. 29, 291; from N. Chem. Zentral-Bl., 1910, No. 8.

Cholestrol—Combination with Saponins.—It has been shown by Ransom that if cholestrol is added to saponin, the latter loses its property of
dissolving blood corpuscles. The compound which is formed has now been studied more closely in the case of digitonin by A. Windhaus. On mixing an alcoholic solution of this saponin with an alcoholic solution of cholesterol, a precipitate of fine crystals falls at once, and this is found to consist of a compound of the two in molecular proportions, no water being eliminated in their union. Many other bodies besides cholesterol were found to form similar compounds; those examined included phytosterol, stigmasterin, coprosterin, \( \beta \)-cholestanol, linalol, geraniol, sabinol, amyl alcohol, and octyl alcohol. Certain other saponins were tried in place of digitonin, and found to give similar compounds.—Pharm. Journ. and Pharmacist, Nov. 27, 1909, 671; from Ber. d. Chem. Ges., xlii (1909), 238, through Nouv. Remèdes, Sept. 24, 1909, 420.

**Cholestrin—Benzoylsuperoxide as Reagent.**—Lipschütz finds that benzoylsuperoxide may not alone be used with advantage for the determination of formaldehyde, but also for the detection of cholestrin, by manipulating as follows: A few fragments of benzoylsuperoxide are added to a solution of several milligrams of cholestrin in 2–3 Cc. of glacial acetic acid and heated to boiling, then cooled. When cool, a few drops of concentrated H\(_2\)SO\(_4\) are added, which settle to the bottom of the test-tube and assume a blue-violet to blue-green color. On vigorously shaking the mixture, the mixture assumes after a short time, depending on the quantity of the benzoylsuperoxide present, an immediate green color, or becomes violet, then fine blue, appearing violet by transmitted light, and only turns pure green after prolonged standing.—Pharm. Ztg., lv (1910), No. 43, 436; from Merck’s Annual Rep., April, 1910.

**Keratin A and B—Soluble and Insoluble Forms.**—Commercial keratin has heretofore proven disappointing for the intended purpose—pill coating—because it has not proven insoluble either in water or in the juices of the stomach. L. Golodetz has, however, now found a method which leads to the production of a satisfactory preparation. According to the statement of the author this method consists in treating horn chips with ammonia under a pressure of four atmospheres, which results in the separation of the horn substance into Keratin A and Keratin B. The latter, after purification from associated albumen, furnishes a suitable material for pill coating, for which purpose it is dissolved in ammonia solution.—Pharm. Ztg., lv (1910), No. 42, 436; from Merck’s Annual Rep., April, 1910.

**Creatinin—Colorimetric Estimation.**—A. C. Chapman has studied Jaffe’s colorimetric method for the estimation of creatinin, and finds that the red coloration on which this method is based depends, not on the formation of creatinin picrate, but on the reduction of the picric acid in alkaline solution to a mixture of amido-dinitro-phenol (picramic acid) and diamido-nitrophenol, the alkaline salts of which are deeply colored. The same coloration is produced by numerous reducing agents, such as nascent
hydrogen, hydroxylamine, acetone, aldehyde, ammonium sulphide and titanium trichloride. Creatinin acts as a powerful reducing agent, and if it is present in excess, the picric acid may undergo reduction and colorless triamido-phenol be formed. The red coloration is due to both the mon-amido and diamido phenol, and solutions of the sodium salt of picramic acid cannot be used for matching purposes. Since the coloration is due to a somewhat complex reducing action, the conditions under which the test is carried out must be fairly closely defined if accurate results are to be obtained. The factor of temperature is of importance, as up to a certain point the color is increased, after which there is a reduction due to the formation of triamido-phenol. With regard to time, slight differences have no appreciable influence. In the cold, and under the ordinary conditions of the test, the presence of dextrose is not prejudicial. The author emphasizes the necessity of working with sufficiently diluted solutions.—Chem. News, Oct. 8, 1909, 175.

**Choline—Possible Errors Regarding its Presence in Animal Fluids and Tissues.**—W. Webster says that several investigators have identified choline as a substance to be found in increased quantities in the blood or cerebro-spinal fluid in animals or patients with degenerative processes going on in their nervous systems. The author points out the various errors on which these and similar statements are based, and shows that with our present methods of chemical analysis there is little hope of detecting the very minute quantities—small fractions of a milligram—of choline that might be set free from degenerating nervous tissue, and so get into the circulating blood of man or of animals, in disease of or after operations on the nervous system. He finds that no choline can be detected in normal blood provided that the lecithin in it is prevented from decomposing. It may be noted that Kauffmann in 1908 could isolate no choline from a liter of cerebro-spinal fluid collected from various patients with nervous diseases. The author further finds that the amount of choline or of potassium salts that might be set free into the circulation by even sudden processes of degeneration in the nervous system would be too small for detection; and that the microchemical reactions given for choline occur irregularly but equally freely by both normal and pathological cerebro-spinal fluid, while it is doubtful whether any of the microchemical tests in use are specific for choline.—Pharm. Journ. and Pharmacist, Aug. 14, 1909, 240; from[Bio.-Chem. Journ, 1909, iv, 117.

**Adrenalin—A New Characteristic Reaction.**—Fränkel and Allers have observed that if solutions of adrenalin are warmed with iodic acid, or with the acid potassium iodate and diluted phosphoric acid, a magnificent rose-red color (or eosine red in extremely dilute solutions) is developed, changing to red-brown on addition of ammonia. The reaction is extremely delicate, being obtained with adrenalin solution 1:300,000, and is
available for its recognition and differentiation from kindred substances which, as determined experimentally, do not give the reaction.—Pharm. Ztg., liv (1909), No. 54, 530; from Biochem. Ztschr., xviii (1909), 40.

Laevo- and Dextro-Suprarenin—Comparative Physiological Action.—According to E. Abderhalden and F. Thies, the physiological action of laevo- and dextro-suprarenin is differentiated as follows: Dextro-suprarenin, when applied to the pupil of the frog's eye, produces no mydriasis; laevo-suprarenin in similar doses produces a marked and characteristic dilatation. Any slight action in this respect that dextro-suprarenine may show is due to the presence of a trace of the laevogyre form. Similarly, dextro-suprarenin fails to produce glycosuria when administered in such doses as cause a marked excretion of sugar in the case of laevo-suprarenin.—Pharm. Journ. and Pharmacist, Dec. 25, 1909, 795; from Nouv. Remédes, 26 (1909), 372.

Parathyroids in Man—Functions.—The "Lancet" (Jan. 8, 1910, 112) makes the following observations regarding the functions of the parathyroids in man: There are usually four parathyroids in man, two on each side, situated in front of the vertebral column just behind the posterior margins of the lateral lobes of the thyroid gland. They are reddish-yellow or reddish-brown in color, and their size and shape correspond to those of a small grain of Indian corn. They are in close relation with the inferior thyroid artery, from which they usually derive their blood-supply. Investigations have shown that when the parathyroids are diseased or injured a peculiar condition of tetany frequently results. The cells of the bodies are different from those in the thyroid, and they form a colloid material which unlike that of the thyroid, does not contain iodine. Professor Ott and Dr. Scott find that removal of the parathyroids causes tetany, that there is a co-operative action between the parathyroids and the pituitary body and that tetany is not due to want of calcium, as some writers have maintained, but to a poison in the blood, the calcium changes being only an epiphenomenon. The tetany can be greatly benefited by pituitary extract, calcium and strontium salts, and by parathyroid extract, and the grafting of a parathyroid is a cure for tetany. A nucleoproteid separated from the bodies is a powerful diuretic, and increases uterine contractions and intestinal peristalsis. The tetany of pregnancy, due to parathyroid insufficiency, can be relieved by parathyroid treatment. A writer draws attention to the difficulty in obtaining sufficient of the extract for investigation, and he insists that satisfactory results can only be obtained by the use of extract made from parathyroid tissue alone, a matter which means that a microscopical examination of every minute gland used in making the extract is absolutely necessary.—Pharm. Journ. and Pharmacist, Jan. 29, 1910, 109.

Tetanus Antitoxin.—In a contribution of John F. Anderson, Assistant
Director of the Hygienic Laboratory of the U. S. Public Health and Marine Hospital Service, he advances some reasons why tetanus antitoxin should be admitted into the next U. S. P., the conditions under which this can be done being identical with those which permitted the admission of diphtheria antitoxin into the present U. S. P. This paper appears in the "Proceedings," 1909, 786-788.

Urine—Direct Detection of Acetone.—Bardash recommends the following direct method for the detection of acetone in urine, which is not interfered with by the presence of albumen, sugar, biliary or urinary pigments, oxalates, etc.: To 3 Cc. of clear urine, 1 Cc. of peptone solution (3 per cent.), 1-2 Cc. of Lugol's solution and 2 Cc. of ammonia are added. On acidulating with hydrochloric acid a precipitate of fine crystalline needles is formed if acetone is present, the reaction being quite distinct in the presence of 0.01 per cent. of the latter.—Pharm. Ztg., liv (1909). No. 81, 798; from Ztschr. f. inn. Med., 1909.

Urine—Detection of Blood.—A. Lejeune recommends the method first proposed by Meyer (1903) for the detection of blood in urine, which depends on the oxidation of phenolphthalin into phenolphthalein by \( \text{H}_2\text{O}_2 \) in the presence of blood. The reagent is prepared by reducing an alkaline solution of phenolphthalein by means of zinc to phenolphthalein as follows: 2 Gm. phenolphthalein and 20 Gm. KOH are dissolved in 100 Gm. water, 10 Gm. zinc powder added, and the mixture stirred or shaken, until with the aid of a small flame it is completely decolorized. It is then filtered hot.

In the examination of the urine for blood, 2 Cc. of the urine and 1 Cc. of this reagent are shaken together and 4 or 5 drops of \( \text{H}_2\text{O}_2 \) (12 vol. per cent.) are added. In the presence of blood, the mixture quickly acquires a rose to a red color, the intensity depending on the quantity of blood present. It is claimed that by this method the presence of blood in dilution of from 1:1000000 to 1:10000000 may be determined with certainty, except in the case of urines having a very high specific gravity. In such cases the method is modified by the addition of 3 Cc. of a 2 per cent. alcoholic solution of acetic acid to 3 Cc. of the urine, then adding 1 Cc. of Meyer's reagent and following this with 3 drops of \( \text{H}_2\text{O}_2 \) as in the previous experiment. In either case the intensity of the red color produced remains for a long time undiminished. Pharm. Ztg., (1910) No. 40, 409.

Urine—Presence of Pentose.—Charles H. LaWall calls attention to a urine recently examined by him for clinical purposes, in which he demonstrated by various tests described the presence of pentose, and the subsequent confirmation by its conversion into and isolation of pentoazone. The comprehensive examination of the urine showed the following: Sp. gr., 1.028; chlorides (as NaCl), 0.94 per cent.; total sulphates (as \( \text{SO}_4 \))
0.31 per cent.; mineral sulphate (as SO₄), 0.30 per cent.; ethereal sulphate (by difference), 0.01 per cent.; phosphates (as P₂O₅), 0.30 per cent.; urea, 3.00 per cent.—Amer. Journ. Pharmacy, July, 1909, 329.

**Urine—Detection of Levulose.**—Reviewing the different methods that have been proposed for the determination of levulose in urine, Dr. A. Jolles, on the basis of careful experiments, recommends the following modification of Ihl-Tchonann’s reaction, which is available in urine containing less than 2.5 per cent. of dextrose. The urine is diluted with 10 times the quantity of water, and to 1 Cc. of the diluted urine 8 to 10 drops of 20 per cent. alcoholic solution of diphenylamine and 1 Cc. of concentrated hydrochloric acid are added, and the mixture boiled for 60 seconds. In the absence of levulose, no coloration results; but if levulose is present in the amount of 0.05 per cent., a distinct blue color is developed within 40 seconds. Urine containing more than 2.5 per cent. and up to 5 per cent. of dextrose, if diluted with 20 times the quantity of water, also fails to produce the color reaction within 60 seconds, but if it contains as much as 0.1 per cent. of levulose the blue color is developed within 40 seconds, as in the previous case.—Apoth. Ztg., xxiv (1909), No. 77, 719; from Rep. of Proc. Germ. Naturalists and Physicians, at Salzburg, 1909.

**Urine—Precaution in Carrying Out Nylander’s Test for Sugar.**—H. Krauss observes that if the urine contains only small quantities of sugar, Nylander’s test may not give a characteristic reaction or may fail altogether. This is due to the simultaneous precipitation of phosphates along with the bismuth precipitate produced on boiling, diabetic urine usually containing an abundance of earth phosphates. The reaction proceeds normally, however, if the urine is first rendered strongly alkaline with NaOH, the precipitate produced is filtered off after a few minutes, the filtrate nearly neutralized with acetic acid, and Nylander’s reagent is then applied in the usual way. A perfectly opaque, deep black liquid is produced, from which the finely divided bismuth precipitate settles very slowly, requiring hours for completion.—Pharm. Ztg., liv (1909), No. 81, 799.

**Urine—Sugar Determination with Orthonitrophenylpropionic Acid.**—Bothe recommends the following as a reliable method for the detection of diabetic sugar if the directions are carefully followed. Using a solution of 3.5 Gm. of orthonitrophenylpropionic acid in 50 Cc. of freshly prepared 10 per cent. solution of NaOH and sufficient distilled water to make 1000 Cc., as reagent, about 8 Cc. of this reagent and 1 Cc. of the urine are mixed in a test tube, and the upper part of the liquid is then carefully heated to boiling. Then, removing the test tube from the flame, a further quantity (about 1 Cc.) of the urine is allowed to flow into the test tube, drop by drop. In the presence of sugar, the mixture assumes a blue color from the top downward, and a greater or less quantity of a blue precipi-
tate, depending on the amount of sugar present, is deposited. In the presence of more than 1 per cent. of sugar, the reaction occurs immediately on applying heat and before the addition of a further quantity of urine.—Pharm. Ztg., liv (1909), No. 81, 799; from Bull de Sc. Pharmacol., 1909, No. 7.

Urine—New Qualitative and Quantitative Method of Estimating Sugar.—The "Journ de Pharm. d'Anvers" describes the following new method for the estimation of sugar in urine: Heat 1C. of the urine, 0.1 Gm. of phenylhydrazine hydrochloride and 0.25-0.3 Gm. sodium acetate to boiling, add 10 Cc. of 3 per cent. solution of NaOH, shake the mixture carefully and set aside. In the presence of sugar the liquid acquires a rose-red to red color, the time varying with the quantity of sugar present and thus making the method available for quantitative estimation. Thus, for example, the presence 1.0 per cent. or more of sugar gives an immediate coloration and 0.5 per cent. in 5 minutes; 0.2 per cent. requires 10 minutes, 0.1 per cent. 20 minutes, 0.05 to 0.02 per cent. 30 minutes for the development of the color. Beyond this time the reaction is no longer characteristic.—Pharm. Ztg., liv (1909), No. 74, 726; from Journ. de Pharm. d'Anvers, 1909, No. 16.

Urine—Detection of Mercury.—F. Glaser and A. Isenburg have made a critical examination of different methods proposed for the detection of mercury in urine. They have obtained particularly good results with the Stuckowenkow-Bardach method, which depends on the precipitation of the mercury by means of albumen from the urine, previously faintly acidulated with acetic acid, heating the precipitate with concentrated HCl in the presence of a copper spiral, and determining the presence of mercury by conversion into HgI₂, in the usual way. Good results were also obtained experimentally by treating the urine with aluminum sulphate and precipitating the alumina by means of ammonia. The alumina carries the mercury quantitatively with it, and this may then be determined by treating the precipitate in the same way as when precipitation is effected with albumen.—Pharm. Ztg., lv (1910), No. 4, 37; from Chem. Ztg., 1909, No. 144.

Urine—Determination of Uric Acid.—Sicuriani recommends the following modification of the Worner-Hopkin method for the estimation of uric acid in urine:—After heating 150 Cc. of the urine, 5 Gm. of ammonium chloride are added, and the mixture is set aside for one-half hour. The precipitate formed is collected on a filter, and washed with 96 per cent. alcohol. To the washed precipitate on the filter 50 Cc. of boiling \( \frac{N}{10} \) potassium hydroxide is then added, followed by hot water, and the filtrate obtained is heated until the vapor evolved no longer reacts alkaline with red litmus paper. After cooling, the solution is then titrated with \( \frac{N}{10} \) sulphuric acid using phenolphthalein as indicator, and the number of
WALRUS BILE. 401–416

Cc. of \( \frac{x}{10} \) potassium hydroxide V. S. consumed, which, when multiplied by 0.056 gives the amount of uric acid in a liter of the urine.—Pharm. Ztg., liv (1909), No. 55, 538; from Arch. d. Farmacol. sperim. 8, 55.

Urine—Presence of Red Coloring Matter.—L. de Jager finds that if urine is treated with hydrochloric acid and formaldehyde, a precipitate of formaldehyde urea is formed, which is of a yellow to brick-red color due to a red urinary coloring matter. The latter may be separated in form of a carmine-red powder by quickly filtering off the first fraction of precipitate. It is insoluble in water, chloroform, ether, benzol, &c., but dissolved when heated with concentrated hydrochloric acid, being again precipitated on addition of water or alcohol. This coloring matter is possibly identical with the "nephrorosein" of Arnold.—Pharm. Ztg., lv (1910), No. 29, 291; from N. Chem. Zentralbl., 1910, No. 10.

Biliary Coloring Matter—Detection.—Emil Abderhalden recommends the following method for detecting biliary coloring matter in body fluids and tissues, as well as biliary calculi, by shaking out the substance in question with chloroform and then adding the chloroform solution to a stratum of Gmelin's reagent (conc. nitric acid containing HNO₃). On careful admixture of the two layers an intense blue-red color is developed, even in presence of very small quantities of biliary pigment.—Pharm. Ztg., liv (1910), No. 29, 294; N. Chem. Zentralbl., 1910, No. 8.

Walrus Bile— Constituents.—In the course of the systematic examination of the bile constituents of Arctic animals, O. Hammarsten has investigated that of the walrus. By fractional precipitation of the gall acids, besides ordinary taurocholic acid, the following acids have been isolated: \( a \)-Phocataurocholic acid, forming fine needles; the barium salt has the formula \( B_{28}H_{41}BaNSO_{8} \), and the free acid, \( C_{28}H_{43}NSO_{8} + 2H_{2}O \). When \( a \)-phocataurocholic acid in 8 per cent. solution of caustic soda is digested for eight hours in a Papin's digester, \( a \)-Phochacholatic acid, \( C_{22}H_{37}O_{9} \), or \( C_{22}H_{36}O_{5} \), is formed, which solidifies on cooling to a crystalline mass. \( \beta \)-Phochacholatic acid was also isolated from another fraction in white needles, sintering at 133° C., and melting between 152°–156° C. A third fraction contained \( \beta \)-phocataurocholic acid, the barium salt of which, and the free acid, were not obtained crystalline.—Pharm. Journ. and Pharmacist, Jan. 1, 1910, 7; from Ztschr. Physiol. Chem., 61 (1909), 454, through Chem. Zentralbl., 1909, 2, 1262.

26
MINUTES

OF THE

FIFTY-EIGHTH ANNUAL MEETING.

The Fifty-Eighth Annual Meeting of the American Pharmaceutical Association was held in the city of Richmond, Virginia, beginning on Tuesday, May 3, 1910, and running through to Saturday, the 7th, inclusive. The headquarters of the Association were at the Hotel Jefferson, on Franklin street, where all the various sessions were held. This was the third time in the history of the Association that it had met at Richmond, the first time being in 1873 and the second in 1900. The members present who had attended one or both of the former meetings were somewhat prepared for the warm-hearted, characteristic hospitality of the capital of the "Old Dominion," but it especially impressed the younger members who were having their first experience of real Southern hospitality. The Governor of Virginia and the Mayor of the city of Richmond, in their welcoming addresses, left no room for doubt as to the sincerity and heartiness of the welcome accorded the Association, and the members present showed every evidence of their appreciation of the generous spirit manifested by their hosts. The meeting was well attended, the increase of membership was encouraging, and the amount of work accomplished was something extraordinary. The number of papers contributed to the various Sections was unusually large, particularly in the Scientific Section, and the interest in the Section meetings was active and sustained. There were several simultaneous meetings of the Sections, and the work of the week was condensed into five days. As was to be expected, the meeting was notable for the discussion of subjects to be brought before the Pharmacopoeial Convention to assemble in Washington City the following week, and a great deal of time and thought were given to the principles which should prevail in the forthcoming decennial revision of the Pharmacopoeia. The entertainment features, though ample and enjoyable, were not permitted to encroach too much upon the valuable time of the Association, and the Richmond meeting of 1910 will go down in the annals of the Association as one characterized by hard work and zeal for the uplift of pharmacy.
FIRST SESSION—Tuesday Morning, May 3, 1910.

The first general session was called to order by President Henry H. Rusby, of New York, at 10:15 a.m., in the convention-hall of the Hotel Jefferson, and the convention was opened with prayer by the Rev. George W. McDaniel, of Richmond.

The President commented upon the fact that it was not often in the history of the Association that it enjoyed the privilege of being welcomed by the Governor of a State, but it had that distinction this morning, and the Honorable William Hodges Mann, Governor of the State of Virginia, would extend a welcome to the Association on behalf of the "Old Dominion."

Governor Mann was fully equal to the occasion, and welcomed the Association to Virginia in an address replete with cordiality, with patriotic fire, and interesting and instructive historic reference. He began by declaring the distinct feeling of pleasure he had in standing before such a body of men to deliver an address of welcome, and with true chivalric spirit proceeded, then, to compliment the ladies and congratulate the members upon having their wives and daughters with them in such goodly number. He remarked that the President had made a mistake in introducing him as the Governor of Virginia; that the real governor he had left behind at the executive mansion—that he was only the lieutenant governor! (Laughter.) He said he recalled that, on one occasion, during the canvass, he had said to his wife, "My dear, if I am elected governor, are you going to be lieutenant governor?" She replied, "I am going to govern you all right." (Laughter.)

Continuing, the Governor said:

"Now I want to tell you something about the State that is bidding you welcome, and I want to say just so much about Virginia as applies to you as well as to us, for much of the history of Virginia—the deeds done in the past, the great men that she has produced—is a part of the history of these United States. And I want you to understand that Virginia is a part of the American Union, and that her sons are going to follow the flag of this great country wherever it goes. (Great applause.) I shall not ask you to share with us in our traditions and in our history to any greater extent than I am willing to share with you in your history and in your traditions, and in the splendid record which your great men of the North have made. I want you to understand that we take pride in the great achievements which have been wrought by Abraham Lincoln, and that the great ability and the splendid magnanimity of Ulysses S. Grant are recognized by us.

"As I have said, much of the history of Virginia is the history of this great country. If you will go down to old St. John's church, on Main Street, you will see the place where Patrick Henry uttered the battle-cry
of liberty which went throughout the length and breadth of this great land, and came back in the echoes from Bunker Hill. If you have time to go down the Potomac river, you will see in Westmoreland county the birthplace of the leader of the army of the Colonies, who was a son of this old commonwealth. And then if you will take the time to read something about the early history of Virginia, and note the struggles which were made for civil and religious liberty—a struggle in which you are just as much interested as we are here, and the results of which you are sharing to-day along with us, you will see how Virginia has wrought in making the history of the American people. It is hard for us to understand in the twentieth century that 156 years ago, everybody, except the people who belonged to the Established Church, had to worship with open doors. They could not be trusted. And when I say outside of the Established Church, I want to be understood as casting no reflection upon that church. The people who settled Virginia were not 'kickers,' they were adventurers. They were satisfied with the conditions at home; they did not come here to change those conditions. They came to better their fortunes, and when they came to settle on the banks of the James river, they brought with them the institutions and the church of the mother country. In England the Act of Toleration was passed. But that Act of Toleration was not considered with the same liberality in the Colonies that it was in England; and, therefore, all those who did not belong to the Established Church were required to worship in that church, unless they were fortunate enough to get license to hold services of their own at certain times and places. But they could not perform the ceremony of marriage in Virginia—and that is a ceremony we have always thought was the greatest, almost, that the church was able to perform.

"Now I have just introduced this subject to show you that there were great struggles in those days, and that there were men of liberal minds in the days of seventy-six. Twenty days before the Declaration of Independence, George Mason prepared and there was adopted in Virginia a paper known as the Bill of Rights. That Bill of Rights declared the principles of the Declaration of Independence, which gave life and vigor to the Constitution of the United States and the Constitution of this Commonwealth; and was the greatest paper ever written, in my judgment, by an uninspired pen; and a paper which had more effect upon the world at large, upon civilized people wherever they lived, than any paper which has ever been written. (Great applause.)

"Gentlemen, I just want to tell you this one incident: After that paper was prepared, the friends and neighbors of Mr. Mason came to him and said: 'Mr. Mason, in recognition of the great work you have done for humanity, we want to send you to the Congress of the United States.' He replied: 'I don't want to go to Congress.' They came back to him again and said: 'Mr. Mason, we are not satisfied: We want the people
of the world to understand that we are grateful to you, and we want to show our gratitude and appreciation by making you Governor of this Commonwealth.' He declined that position. They returned to him the third time and said: 'We want to make you a Senator of the United States.' He declined that. They came to him again the fourth time and said: 'We want to nominate you for President of this great country.' He declined that honor. They then said: 'Mr. Mason, what do you want?' He said, 'I want liberty for my children and my children's children.' (Great applause.)

"About twenty days after the Bill of Rights was adopted, as I say, the Declaration of Independence—prepared by another Virginian—became the great paper, the great foundation stone of our liberties. And just here it may not be improper to remark that the first written Constitution of a free people was adopted in this old Commonwealth. It blazed the way for every other Constitution that has ever been written. And it had embodied in it the great principles of the Bill of Rights of this Commonwealth.

"Then, when we were a struggling nation, and it was necessary for the Constitution to be so construed as to give power to the government to carry into effect the plans and purposes of the fathers, once more the Colonies came to Virginia—the States came to Virginia—and got John Marshall as the great expounder of the Constitution. And in passing I would like to say that all the cases which John Marshall decided, construing the Constitution, with the single exception of the Income Tax, have never been reversed by the United States Supreme Court from that time until this time.

"Just one other thing: When we were a struggling people, when we were weak and almost helpless in the eyes of the world, a Virginian had the courage to stand up and proclaim the Monroe Doctrine—had the courage to say to the European nations, 'You cannot come on this side of the Atlantic and establish your institutions. America is for Americans!' (Great applause.) We do not realize now how much courage it required to make that declaration, but if we look back at the conditions that existed then we can see that it required a brave man to stand up in the face of the European nations and make it.

"I have stated these things to you, my friends, because the history of this Commonwealth is a history in which you have an interest. You have part and lot in what has been done by the glorious sons of this old Commonwealth. I tell you these things because I want you to understand the State to which you are being welcomed. We have made history here in the old Commonwealth, and we are prepared to show to you not only the history we have made, but, thank God, there are some people left who helped to make it. And we want to say to you again that, not only has the old Commonwealth produced great men in the past, but if the time shall ever come in the history of this country when there shall be need to
call upon its manhood for protection or to maintain its glory, the sons of Virginia will answer to that call.” (Great and prolonged applause.)

Continuing, the Governor proceeded to say that he did not mean by all this to omit the ladies; and, to illustrate his attitude, he told a good story of John Hay, late Secretary of State, to the effect that when as a young man he was one of the attachés of our embassy to France, and was called on upon one occasion to make a speech and respond to a toast, “Our Countrywomen,” repeatedly, through habit, spoke of them as “My Countrymen,” and finally excused himself upon the ground that “the latter always embraced the former, anyhow.”

The Governor then went on to say: “Now, it is my pleasant duty to welcome this Association of Pharmacists to old Virginia. Mr. President, I would bring you the keys, but we haven't anything locked. We knew you were coming, and we have just opened everything. Our doors, our city, our hearts and everything are open to you, and you can just come in and take possession. So it is not necessary for me on this occasion to deliver the keys.

“Now I want to say that, from my standpoint,—and I am sure that all thinking men must agree with me,—a body of men such as I am now addressing must be an important factor in the development and welfare and health of this great country. And we have a great country, the greatest that the sun ever shone upon! (Applause.) Somebody has said that even if the hogs that are annually killed in this country were put together in one great hog he could “dig the Panama Canal in two roots and a half.”

The Governor then went on to pay tribute to the great advance made in the practice of medicine in the past twenty years, declaring it to be his belief that medicine led all the other professions. He said he believed that a great deal of the advancement attributed to surgery was due to discoveries in medicine in the way of antiseptics, etc., which enabled the surgeon to do things to-day that he could not do twenty-five years ago. He then continued: “The doctor writes the prescription, based upon his diagnosis of the disease, and it is left to the skilled druggist to compound the remedies to give relief to the sufferer. The doctor writes the prescription; but suppose the druggist makes a mistake in compounding that prescription, what becomes of you? Then if the doctor makes a mistake, the skilled druggist detects it and points it out to the physician; and he won’t put up a prescription which will do positive injury to the man for whom it is intended. I say, therefore, that the skilled druggist is a court of last resort, and we owe much to his integrity and efficiency. They say if the doctor makes a mistake he buries it; but I can truthfully say, in all my lifetime, I have never heard of as many as half a dozen mistakes being made by druggists. I think that is a record of which any profession might be proud.
"Now, the druggists are influential men—they are obliged to be so. They are men trusted in the community. They are obliged to be so, because they have the lives of the people in their custody. They are men of influence with their neighbors and friends. I have very rarely heard of one of them being a candidate for a political office, and as long as I have been Governor of this Commonwealth I have never had one of them apply to me for any position. I take it, therefore, that while they are influential men, intelligent men, worthy men, they are men who do not obtrude themselves upon the community. I will tell you what is a fact: I didn't know what a good set of people the druggists were until I commenced thinking about this address. I don't just believe there are any better people on the face of the earth.

"Now, my friends, I just want to make one statement. Perhaps I ought to have told you in the beginning, but I forgot it. The best part of my speech is always the last, and I have just looked at my watch and I find I have not got time to make it. (Laughter.) So that when you go away from here, if you can think of any good things I have not said, or which would be appropriate, you may know that I had it all ready to say, but just didn't have time to get it out.

"Now I must quit. Here is the Mayor back here, and he is anxious to make you a speech, and it is impossible for him to hold in five minutes longer. So I just want to say in conclusion that the old Commonwealth of Virginia, of which I have the honor to be Governor, extends to you a hearty welcome to her heart and home." (Great and continued applause.)

The President called on Mr. Henry M. Whelpley, of St. Louis, one of the permanent officers of the Association, because of his location in the Central West, and because of his continued attendance for many years at the meetings of this Association, thereby becoming acquainted with members from all parts of the country, to respond to this eloquent, warm-hearted and patriotic address of welcome from the Governor of Virginia.

Mr. Whelpley responded at length. He said, that, having on previous occasions experienced the hospitality of the State of Virginia—a State renowned for its hospitality,—he was prepared to hear the warm words of welcome from the Governor. He declared that nothing that could be said could exaggerate what was meant by hospitality in Virginia. He also felt that it would be difficult to exaggerate the appreciation of that hospitality on the part of the members of this Association. He said that in listening to the eloquent address of the Governor he felt more like sitting in silence and pondering over the instructive information he had given than attempting a response. Referring to the suggestion of the President that he would call upon him to respond as a member of the Association from the Central West, he said that in the Central West they had learned to know and appreciate the citizens of Virginia wherever they had
settled among them. They had always been good citizens, and many of them had been, and were now, among their leading educators. The experience of the Central West in this behalf he declared to be but an echo of what is found as to Virginians throughout the entire United States.

Continuing, Mr. Whelpley said that the American Pharmaceutical Association had discovered the rare hospitality of the State of Virginia as far back as the year 1872, when it was decided to meet at Richmond in the following year, at which meeting in 1873 the late Albert E. Ebert, who was the first to establish an endowment fund for the Association, presided as President. He then briefly traced the history of this fund, starting at the sum of $500, and doubling itself since that time by accretions of interest. Starting with this small nucleus, the total invested funds of the Association had now grown to something like $30,000, the interest upon which sum only could be used. Mr. Whelpley referred to the election of Mr. John F. Hancock, of Baltimore, as President at this meeting, and paid high tribute to his character as a man, and characterized his annual address at the succeeding meeting as one of the ablest papers of its class that had ever been delivered before the Association. Mr. Whelpley went on to say that the Association was so impressed with Virginia and the city of Richmond, that along about the year 1898 it began to think of making a return visit, upon the hearty invitation extended by Mr. T. Ashby Miller and his associates, whose "On to Richmond" cry was too potent to be resisted. So the Association met again in Richmond in 1900, and the presiding officer that year was the late Albert B. Prescott, of Ann Arbor, Michigan, whose name would ever stand out in the history of the Association as that of a man distinguished for his scientific attainments and for his long life of usefulness in the cause of pharmacy. At that meeting of 1900, Mr. John F. Patton, of York, Pennsylvania, was elected President for the ensuing year; and who, like Mr. Hancock, of Baltimore, was present at this meeting—returning again to the historic city of Richmond.

Continuing, Mr. Whelpley assured the Governor that the American Pharmaceutical Association appreciated the privilege of being once more in the capital of the "Old Dominion." He said this Association was the broadest organization of pharmacists in the world. No other organization included every class connected with or interested in pharmacy—the retailer, the wholesaler, the manufacturer, the physician, the editor, the chemist, the clerk—every individual interested in pharmacy being eligible to membership in it. He said the Association had come to Richmond for work, and that it was not an organization of speech-makers. It was in no way akin to the young lawyer who thought in multiplicity of words there was strength, and when he had put the judge and jury to sleep, apologized to the court for trespassing upon its time, eliciting the retort, that "to trespass upon time was one thing, to encroach upon eternity was quite
another." He concluded by saying that the members could easily en-
croach upon eternity in expressing their appreciation of the good things
set before them, but they would desist and make use of their opportunities
for enjoyment.

The President stated that the Association was doubly fortunate this
morning, in that it not only had the Governor of the State to welcome the
members, but that his Honor D. C. Richardson, Mayor of the City of
Richmond, was also present, and would extend a welcome on behalf of
the municipality which he represented.

Mayor Richardson came forward amid the applause of the members,
and delivered an eloquent address. He started out by saying that after
the able and witty speech of his Excellency the Governor, and the re-
response made thereto, he felt that his duties and privileges were somewhat
curtailed. He said that as he sat and listened to the speech of the
Governor, abounding as it did in wisdom and wit, and noted the laughter
evoked by his witticisms, he could not but ask himself the question, "Is it
really true that the Chief Executive of Virginia, who is thus addressing this
audience, is the dry Governor that he is said to be?" He was constrained
to believe this was a mere newspaper slander. He was forcibly reminded
of the advice given to a young but overtrusting barrister by an old and
very practical justice of the peace, before whom he had made a somewhat
startling statement, and who, when called upon for his authority, said he
got it out of the newspapers, that it was a safe plan for a man "to believe
only half that he saw, but very little that he heard, and not a darned thing
that he has seen in the newspapers." The Mayor then proceeded to throw
some "bouquets" at the pharmacists of the country, whom he declared he
had known for forty years "as the best people on the face of the earth." He
also proceeded to compliment the ladies, denying that they were along
to watch their husbands, as the Governor had facetiously intimated in his
remarks, and declared that the pharmacists had gladly brought their wives
because they wanted to show the people of Richmond the beautiful and
accomplished women they had for their life companions. The Mayor
then proceeded, in the warmest terms, to welcome the Association to the
city of Richmond, a city which he declared had no keys and no need of
keys, for it had neither locks nor walls for this Association, but everything
was wide open—except on Sunday. The Mayor then waxed eloquent as
he proceeded to dwell upon the history of Virginia and the city of
Richmond.

"We welcome you to our city—to this historic city of ours; the oldest
with one exception,—and I can hardly make that an exception,—the
oldest settlement on the American Continent. There was a temporary
settlement at Jamestown, but in the result it can hardly be called by that
name. On the 24th day of May, 1607, eleven years before the landing of
the Pilgrims at Plymouth Rock, a band of adventurers who had sailed across the unknown seas sailed up our beautiful river, and here, within half a mile of where we stand, upon an island in the river, planted the Cross, the symbol of Christianity, and in the name of their sovereign, King James I of England, then and there took possession of the country and established a settlement here at Richmond—a settlement which, with but slight interruption, has existed until the present day; the little town, in due time, giving place to the city which succeeded it. This settlement passed through as many vicissitudes as any settlement, town or city on the American Continent. Here within the sound of my voice, almost, rang out the war-whoop of the Indians in deadly contest with the settlers, and the little stream on the western border of our city ran red with the blood of the savage and the British, and still bears the name of 'Bloody Run', in memory of that sanguinary conflict. It was here during the Revolutionary War that the tocsin of war was sounded in a building which still stands, and in which the worshipers gather each Sunday to send up their prayers of thanksgiving to Almighty God. It was here that many of the distinguished men of the Colonies in early days lived and worked and endured. It was here in this city—and the building is still standing—in which that great chief justice, John Marshall, for more than thirty-five years, lived and labored and loved; and while he did not die yesterday, in one of our cemeteries, beside those of his beloved wife, his ashes now repose. It was around our city that contending armies fought and bled. It was here that a mighty effort was made to disrupt this Union. It was here that devoted men, equally earnest in their ideas of right, opposed determined front, those without seeking to capture the city, those within opposing with all their might the beleaguering host. It was here that devoted women went through our streets and into our homes and hospitals, ministering to the suffering and dying. It was this devoted city that suffered frightful disorder and destruction by fire and sword, and all the horrors of war. But, my friends, I want to say that Richmond, although she was crushed down and destroyed, has arisen from her ashes, and has taken her place again among the cities of this great Union. She has turned her face to the east, and is keeping step with the great onward march of Progress. (Great applause). And, my friends, we who live here,—we who endured the trials and privations and dangers of those days,—while we cherish with affection all the reminiscences of the past, have buried all the hate and animosities of those days, and the flag of this Union is our flag, and this country is our country; and if the foreign foe menaces us, the men of Virginia and the men of Richmond will march side by side with the men of any other State or city in the Union, to uphold the glory of our country and the honor of our flag. (Great applause).

We welcome you to Richmond, ladies and gentlemen. I know that these words of mine are superfluous, for already men who are members of
this Association, and who reside here, have given you the warm grasp of fellowship, and you have seen in their bright faces that welcome of which that warm grasp and that pleasant smile are the assurance. Ladies and gentlemen, I thank you.”  (Great applause.)

The President called on Mr. James H. Beal, of Scio, Ohio, to respond to the address of welcome delivered by the Mayor.

Mr. Beal discharged this duty handsomely, and assured the Mayor of the sincere appreciation of the members of his warm words of welcome. He said the members would bear with them for many a day after leaving the precincts of the municipality of Richmond, and the borders of the “Old Dominion,” a happy recollection of the sentiment that had been so eloquently voiced. Continuing, he said in part: “We not only concede to the ‘Old Dominion’ a glorious history and a heritage of many great men, but we claim and demand it as our right to participate in these glorious recollections, as a part of the heritage of the American nation. We teach it in our schools, and the first name of American citizenship which our children are taught to lisp and to love with veneration is that of a great Virginian. You realize, and we realize, that there is scarcely a great principle of American jurisprudence to-day that did not originate or receive a strong vitalizing impulse from the citizenship of Virginia. We recognize that, and we pay our grateful homage to the “Old Dominion” —a name which we utter with love and respect, as we think of what we have received from this grand Commonwealth.”

Mr. Beal referred to the former meetings of the Association at Richmond, and said that each time the Association had borne away with it an appreciation of the hospitality and the excellence and the worth of the citizenship of the city and State, and the part which they had played in American civilization. He thanked the Mayor very heartily for his welcome, and assured him that the acceptance of the members would fully measure up to the warmth of his greeting.  (Applause.)

By invitation of the Chair, Mr. E. H. Ladish, of Chicago, as the accredited representative of the National Association of Retail Druggists, next addressed the Association in words of greeting from that body. Not being accustomed to make extemporaneous remarks, Mr. Ladish had reduced what he had to say to writing, and he spoke as follows:

“Our delegation have the pleasure of bringing the warmth and interest of the N. A. R. D. We wish you continued success and trust your convention will yield the usual good crop. Your fifty-seven years of usefulness stand out very prominent in matters of pharmaceutical import, your accomplishments have been many, and we are very proud of the daddy of the pharmaceutical associations of America. We are looking forward with interest to the issuance of the new edition of the National Formulary, and I want to pledge our association to again help you to place this little
grant if possible in every drug store in the United States. Mr. President, I have the distinguished honor of wishing your Association a long and useful career, and now with a Godspeed I must say Auf Wiedersehn."

Also, by invitation of the Chair, the Association was addressed by Mr. Edgar D. Taylor, of Richmond, as the accredited representative of the National Wholesale Druggists Association. Mr. Taylor said the National Wholesale Association extended their heartiest greetings, and hoped that the meeting would result in great good to this noble Association. He said if he mistook not, his association was next in years to this. He welcomed the Association to Richmond again, and said that not only the National Wholesale Druggists Association, but that every druggist and jobber and retailer in Richmond wished for the Association an indefinite stay. (Applause.)

The President next called on Mr. M. I. Wilbert, of Washington City, to address the Association on behalf of the Public Health and Marine Hospital Service. Mr. Wilbert extended the felicitations of Surgeon General Wyman, of the Public Health Service, and assured the Association that General Wyman had repeatedly expressed his appreciation of the public-health work that this great Association was doing, and thoroughly appreciated its efforts in that direction. Mr. Wilbert said that the pharmacists of the country were not, as a rule, aware of the great extent and importance of the work being carried on by that department of the Public Service; and he wanted to ask the privilege of presenting to the Secretary a short outline of the work that was being done, so that the members might, at their leisure, study over the possibilities of their work, and the possibilities of cooperation with the Public Health Service, and learn something of the meaning of its present-day activities. He said that the assertion had often been made that the Public Health Service did not extend to pharmacy the recognition that was its due. This assertion, he said, was unfounded, and would be proven to be so to the satisfaction of those who would take the time to thoroughly study the work that was being done by that bureau. He spoke of the scientific research work that was being done and carried on as a division of the work of Public Health and Marine Hospital Service, and the several branches into which the scientific work was divided. One of these was the Division of Bacteriology and Pathology, which is devoted to work along pharmacy lines. That division had the care of the standardization of serums. In his judgment, no more important product or medicine is used in this country than serums. Then the Division of Chemistry was also doing work along pharmaceutical lines. The Division of Biology, which had done so much to call attention to the diseases peculiar to the Southern States, was doing work of interest to pharmacists, and he thought the pharmacists of this country should get in touch with work being done under the auspices of this division and the
Rockefeller Foundation in connection with the work on hook-worm. He advised the southern pharmacists, especially, to procure a copy of a late bulletin on soil pollution. Also, that the members generally should secure a list of the publications of this Public Health Service, and send for such publications as appealed to them, and thereby learn how much of really valuable work the Service was doing at the present time, and how much more it could do if the pharmacists of the country would take an interest in that work and cooperate with it. (Applause.)

PHARMACY AND THE U. S. PUBLIC HEALTH AND MARINE HOSPITAL SERVICE.*

Despite the fact that for upwards of a decade representatives of the Public Health and Marine Hospital Service have regularly attended the meetings of the American Pharmaceutical Association there appears to exist, even among pharmacists, a lack of appreciation of the varied and far-reaching efforts to protect the health of the American people that are now being made through the several divisions of the Service.

The Public Health and Marine Hospital Service, as now organized, is a bureau of the U. S. Treasury Department, and had its origin as the "Marine Hospital Service" in 1798. This Service was reorganized in 1870 and in 1902; its duties were materially augmented and its name changed to "Public Health and Marine Hospital Service." The varied activities of the Service are in a measure reflected by the titles of the administrative divisions, which include: Marine hospitals and relief, domestic quarantine, foreign and insular quarantine, sanitary reports and statistics and scientific research.

More detailed information regarding the activities of these several divisions is obtained from the Service publications, which are classified under five heads: 1. Annual Reports, 2. Weekly Public Health Reports, 3. Public Health Pamphlets and Brochures, 4. Bulletins of the Yellow Fever Institute, and 5. Bulletins of the Hygienic Laboratory.

The importance of the work done in connection with quarantine service at domestic ports is evidenced by the fact that during the fiscal year ending June 30, 1909, no less than 8,266 vessels were inspected and 520 were disinfected as a precaution against yellow fever or plague. Foreign quarantine work includes investigations into the sanitary history of vessels destined for ports in the United States, the inspection of vessels' crews and passengers and the fumigation or disinfection of ships when necessary.

The Division of Sanitary Reports and Statistics of the Public Health and Marine Hospital Service collects information regarding the existence and prevalence of quarantinable diseases, and the nature and effect of sanitary measures adopted by other countries.

* This essay, submitted by Mr. M. I. Wilbert, is inserted here as germane to the remarks previously made by the author. (The General Secretary.)
Much of the scientific research done in connection with the Public Health and Marine Hospital Service is carried on in the hygienic laboratory. The original building of this laboratory, located at 25th and E Sts. N. W., Washington, D. C., was occupied in 1903, and the more recent extension was completed in 1909. It is a brick and sandstone structure, 230 feet long, two stories in height, with a basement and attic, and contains 41 rooms.

The personnel of the Hygienic Laboratory, at the close of the last fiscal year, comprised a total of 55 persons: A director, an assistant director, 3 chiefs of divisions, 8 commissioned medical officers, 2 pharmacists, 11 technical assistants, an artist, and 28 attendants. To facilitate the pursuance of the scientific work, the laboratory is divided into divisions more or less distinct and independent of each other. These divisions include:

1. Division of Pathology and Bacteriology.
2. Division of Zoology.
3. Division of Pharmacology, and
4. Division of Chemistry.

The work that has been done in connection with the several divisions of the Hygienic Laboratory has attracted widespread attention, and is generally recognized as being of great scientific value.

As a practical illustration of the appreciation of this work by individual citizens, it is but necessary to call attention to the recent gift of $1,000,000 by Mr. John D. Rockefeller, for the purpose of eradicating hookworm disease from the Southern States. This gift is not alone a recognition of the scientific character of the work done in the Hygienic Laboratory, but is also a tribute to the ability and worth of the chief of the Division of Zoology, who was the first to call attention to the now recognized prevalence of hookworm disease in the Southern States.

In addition to hookworm disease the Public Health and Marine Hospital Service largely in, or under the auspices of the Hygienic Laboratory, has carried on extensive investigations on the causative factors and the possible prevention of tuberculosis, yellow fever, plague, leprosy, typhoid fever, pellagra, diphtheria, tetanus, rabies, and other infectious and contagious diseases.

The Hygienic Laboratory is by law entrusted with the supervision of the manufacture and sale of sera, vaccines and similar products, and the Division of Bacteriology has evolved and perfected standards for antituberous serum and for antitetanic serum that have been accepted without question by the manufacturers of these products, and have been favorably commented upon and endorsed by bacteriologists and scientists generally.

The Public Health and Marine-Hospital Service has been repeatedly accused of not giving to pharmacy the recognition that it rightfully de-
serves in public health work. That this accusation is unfounded and is, in fact, based on a misconception of what pharmacy itself is, or should be, is evidenced by the work in connection with the Division of Pharmacology of the Hygienic Laboratory.

Even at the present time this division is exceeded in size and importance only by the Division of Bacteriology and Pathology, and the scientific work that has been done under the direction of its chief, Dr. Reid Hunt, is widely recognized as being of great scientific value. This work is particularly interesting in that it is of prophetic import; being representative of the future of pharmacy and indicative of the work that can be, and very properly should be, done, by the professional pharmacist if he is to continue as the accepted authority on information relating to drugs and medicines.

Much of the work that has been done up to the present time relates more or less directly to the materials included in the Pharmacopoeia of the United States.

One of the earlier bulletins emanating from the Division of Pharmacology, included a discussion of the changes in the U. S. P. VIII, particularly the nature and properties of the new remedies that were included in that book.

More recent bulletins deal largely with compilations of comments on the Pharmacopoeia of the United States and the National Formulary. These compilations are being prepared at the request of the Board of Trustees, and, it is expected, will be of material assistance in the forthcoming revision of the U. S. P.

While much routine work is done in connection with the examination of chemicals and pharmaceutical supplies, the possibility of making original investigations is not lost sight of and the hours devoted to such investigations are by no means limited to the working hours prescribed by the Government regulations.

The publications emanating from the Division include communications on the study of the various suprarenal preparations, the standardization of preparations of the thyroid gland, the toxicity of acetylsalicylic acid reactions, the variability and methods of standardization of preparations of digitalis, the solubility of pharmacopoeial compounds, the melting points of chemical substances and the reduction of the U. S. P. analytical methods to the purity rubric.

Even this meagre record should suffice to convince the most skeptical that in at least one of the Government Medical Services, Pharmacy, "Pharmacia Vera" has received proper recognition and that the work now being done in the Division of Pharmacology of the Public Health and Marine Hospital Service is destined to open up for true pharmacy a field of activity that is as yet but imperfectly occupied.

The President said he thought the Association should value very highly
these remarks of Mr. Wilbert, as it was a practical, valuable communication to pharmacists. He thought it was not possible for the people of this country to know too much about the work that was being done at Washington by the different departments. He also reminded the members that it was absolutely impossible for the federal government to make headway in its work along pharmaceutical lines without their co-operation and assistance. He then called on Mr. Lyman F. Kebler, of Washington, to present a synopsis of the work being done along these lines by the Department of Agriculture.

Mr. Kebler began by saying he regretted to have to state that Dr. Wiley, the chief chemist of the Department of Agriculture, could not be present, but it would give him pleasure to explain the nature of the work being done by the Department. He said that the Bureau of Chemistry in that Department looked to this Association for support and sustenance in many ways. For instance, in the Bureau of Chemistry they have a Division of Foods, which looks to the food questions of the country. There is a Division which looks after such things as mineral waters. Then there is a Division of Drugs, which is placed in the hands of one wholesaler and one retailer, who are charged with the ascertainment of the genuineness of the product. The Department has laboratories in all of the large cities of the country—New York, San Francisco, Seattle, Portland, Galveston, Cincinnati, Philadelphia, Baltimore, Chicago, Detroit, Savannah, etc. These laboratories are watching the character of goods that are brought into this country and examining the articles that are sent from the adjacent countries in which they are located. Mr. Kebler said he hoped that those who proposed to attend the Pharmacopœial Convention at Washington next week would make it a part of their pleasure and duty to go to the Department of Agriculture and inspect for themselves some of the work they were doing, the actual results being accomplished, by inspecting some of the reports of the results obtained there.

Mr. Murray Galt Motter, of Washington City, was next called upon to convey the greetings of the American Medical Association to this body, and he did so at some length, saying that at a meeting of the Section on Pharmacology and Therapeutics of the American Medical Association, held in Atlantic City in 1909, the chairman of the delegation from the American Pharmaceutical Association requested that the Section on Pharmacology and Therapeutics appoint a committee to cooperate in the revision of the National Formulary, and that in compliance with that request the Chairman appointed a committee consisting of Doctors Robert A. Hatcher, Torald Sollman, Lyman F. Kebler and Reid Hunt. The Chairman of that Committee had signified his intention of being present at this meeting to make report for the Committee. It must be obvious to all that the work that had been done in the last four years, and notably in the last two years, towards increasing a knowledge of the United States Pharma-
copœia among the medical profession had been very great. He referred the members to the significant reports made at the last meeting of the American Medical Association on the part of the Sub-Committees and Sub-Sections. The Section on Practice, the Section on Obstetrics, the Section on Ophthalmology and the Section on Pharmacology and Therapeutics had given much attention to this subject. This work was undertaken at the suggestion of, and in many ways by the direction of, the Chairman of the Committee on Pharmacology. All these reports were evidence of a growing community of interest between the two professions. Never before, perhaps, have the times and conditions been so opportune for efficient, practical cooperation between the medical and pharmaceutical professions.

This ended the oral addresses of welcome and greeting, and the General Secretary was given opportunity to read a telegram of cordial greeting and good wishes from the Los Angeles Retail Druggists’ Association, as follows:

LOS ANGELES, CALIF., May 2, 1910.

Dr. H. H. Rusby, Pres. A. Ph. A., Care Hotel Jefferson, Richmond, Va.:

Los Angeles Retail Druggists’ Association sends its greetings, and wishes each member health, happiness and good cheer. May God crown and prosper your good work.

W. R. DICKINSON, Pres.

On the motion of Mr. Philip Asher, of New Orleans, it was understood that the General Secretary would make an appropriate response to this telegram.

The General Secretary next read a communication from the Women’s Auxiliary of the National Retail Druggists’ Association, as follows:

April 29th, 1910.

The American Pharmaceutical Association, Richmond, Virginia.

Dr. H. H. Rusby, President.

Dear Sir: The Woman’s Organization of the National Association of Retail Druggists sends you hearty greetings, and best wishes for a most successful meeting upon this your fifty-eighth gathering. For over a half a century your organization has stood for the highest ideals in American pharmacy and has rendered services which have been of lasting benefit to our calling: we congratulate you. We hope that the future will bring you still greater honors; we hope that the future will bring honors also, to all the pharmaceutical organizations of this country, and that all may co-ordinate their efforts, and make their work for the uplift of American pharmacy and the betterment of the conditions of pharmaceutical practice, more effective; and in this work we wish to assist, not as pharmacists, but in our own sphere, as members of a woman’s pharmaceutical organization.

Sincerely and fraternally yours,

NELLIE FLORENCE LEE, President.
ESTALLENE A. FORBRICH, Secretary.

EMILY M. MORRISON, Chairman of Fraternal Relations.

The President stated that, as far as he recalled, this was the first time
the Association had ever had greetings of this kind from the members of the Women's Association. He called for action upon the communication.

On motion of Mr. Thomas P. Cook, of New York, the letter was received, and the Secretary was directed to send an appropriate response thereto.

The Chair here gave opportunity to Mr. T. Ashby Miller, Local Secretary, to make a statement, and Mr. Miller proceeded at length to outline the various features of entertainment provided by the Local Committee for the visiting members and their ladies during the week of the Convention. This program, he said, was in print, but the members had not seen it as yet. The Chair stated that, at the proper time, he had no doubt the Association would formally express its appreciation of the work done by the Local Committee, but he wanted to take this opportunity to express his own personal appreciation and gratification at the program of entertainment that had been mapped out for the members. He said he thought it was due to the Secretary, Mr. Miller, and his committee of ladies and gentlemen, to make preliminary acknowledgment of the program which had been provided for the entertainment of the members of the Association.

The President announced that the time had now arrived for the reading of the President's Annual Address, and he would ask that Mr. C. B. Lowe, of Philadelphia, First Vice-President; take the chair, while he read this paper. He thought it was proper to preface the reading by a brief statement: The American Pharmaceutical Association ought to number in its membership a majority of the pharmacists of America. But the great majority of pharmacists will not join the Association, unless they have some good reason for doing so. It cannot be expected that they will seek out the Association and ask to connect themselves with it, unless the Association itself can show them it is going to do them some good. That is human nature. The general thought that had been in his mind, therefore, throughout the preparation of his address, had been the vital question of membership, and coupled with that the query: What can we do to make it worth while to the many thousands of pharmacists in America to become members of the American Pharmaceutical Association? This, he said, had been the thought which had been uppermost in his mind during the whole time he had given to the preparation of his address, and it was a subject to which he asked the earnest attention of the members this morning.

Vice-President Lowe took the chair, and President Rusby proceeded to read his address as follows, interspersed with numerous explanatory and amplifying remarks:

28
Fellow Members: It has seemed to me that nothing could be more fitting on the present occasion than a plain, practical discussion of the work of the Association, and the best methods of its performance. Two reasons, among others, have especially influenced me in this decision. The fact that the recommendations made last year by President Oldberg for rather sweeping changes in our working organization are this year to be presented by the Council for your consideration will impart an unusual value to a discussion of this subject. I have, moreover, long been impressed, and more strongly so since my election as President has called me to a more careful study of the Association's history and welfare, with the feeling that we are relatively failing in the accomplishment of our mission. Lest this statement may be construed as indicating a want of appreciation of what we have done, I desire to express the high satisfaction with which I have scanned our Proceedings of previous years. These volumes are replete with useful scientific information, much of it originally contributed by our own members, and with sound views on professional subjects. It remains true, however, that we have failed to gather in much, if any more than five per cent. of the eligibles in this country, and that the principles which we espouse rule but the majority of our profession. In countries where such societies are official, and where membership exists by virtue of the profession, numbers mean nothing; but where, as here, membership and activity are voluntary, the extent of membership does have much force in determining conditions. Briefly stated, it is the mission of this Association to establish the practice of pharmacy in this country upon the ethical and professional basis that we approve, and to do so in a way not inconsistent with business success. But two ways are open for accomplishing this object, namely, the increase in our membership and the extension of our influence among non-members. It is with this in view that I speak of a relative failure in the accomplishment of our mission.

It is in no Utopian sense that I remind you that our Association and the profession that it represents are but means to an end, and that end, ultimately, an unselfish one. I that our Association, profession and individual business exist for the welfare of those whom we serve is asserted in the statement of our objects, set forth in the constitution to which we have all subscribed. Attention to this truth should therefore be the consideration that determines the handling of every question that arises regarding the policy and proceedings of the Association. Your speaker can conceive of no other basis of consideration of the problems which to-day confront us, and his official advice and recommendation on the present occasion are determined wholly in the light of professional duty, and of experience as determining the most successful method of its performance.

It is thus the object of the A. Ph. A. to advance the profession of pharmacy in such ways as shall most fully and perfectly fit it for benefiting its dependents and patrons, and to strengthen its own organization so as to increase its means for performing this service.

My distinguished predecessor in this office stated some unwelcome truths regarding conditions in American pharmacy. It was their unwelcomeness, and not a want of accuracy of statement, which chiefly excited hostility. Now, eight months after their promulgation, they are looked upon in a far more kindly spirit than that in which they were originally received. The extent of this difference is one measure of the year's advance of this Association. Flattery is sweet, but faithful are the wounds of a true friend. Little advance is to be made through the repetition of already accepted truths. Real progress is accomplished by those who struggle for the recognition and acceptance of the worthy new.

I shall not here dwell upon the errors and shortcomings of pharmacy. They have
been set before you over and over again, from many sources and in many ways. But few of us will recognize and realize them all. Most of us will do so with regard to most of them, and none will fail to do so as to all of them. Set your thoughts upon any one of them that you may select, and answer whether the constitution of this Association is not directed straight toward its correction. You cannot answer "nay." Survey the field of retail pharmacy, in the light of what it should be, judged by your individual pattern, and we shall all be united in our desire and effort to improve it, whatever may be the particular line of work that appeals to our respective individual idea.

How the Association can best accomplish these results is the problem which has specially occupied my attention during the past year, and it is the resulting views which are now submitted for your consideration. Of necessity, these considerations apply to the professional side of our work. Quite as necessarily they apply to the material side, not because the two are at all coordinate in rank, or worthy to be compared in their ultimate importance, but because our material prosperity contributes the only possible basis for the performance of our professional duties.

It may be here remarked that as my ideas concerning the functions of our more important committees, and the necessities for their administration crystallized, I deemed it proper to communicate them to the respective chairmen. In some instances, these chairmen have seen fit to apply my ideas in the work of the present year, and from them you will doubtless hear expressions of approval, or the reverse. The most careful study that it has been possible for me to make of the conditions in and the relations of our Association has convinced me that the key to our success lies in the extension of our membership. This conclusion rests upon two facts. First, the need of funds for carrying on our work; second, the influence of membership upon the members and upon the communities in which they live and which they ought to represent in the Association.

Although the Association has some other sources of income, the principal and almost the only source to which it can look as a certain permanency, is its membership dues. The Treasurer is authority for the statement that these dues alone would be insufficient to support its present activities, yet it is true that the success of these activities is even now curtailed by the want of funds. Those of us who have kept in close touch with the Association's activities through a series of years can recall not a few propositions for the performance of good and important work which have been rejected because we had not the money requisite for their execution.

That the good influence of membership in the Association is immeasurable can be seen by observing its effects, either upon the individual members or upon the community. It is impossible for any man to come within the sphere of influence of our annual meetings, or of our publications, without becoming thereby a worthier member of the guild; and no one can travel over this land, observing and contrasting the conditions of pharmacy in the sections which are and are not well represented in our membership, without seeing that the former are, other things being equal, of a higher type, regarded from almost any point of view.

These and similar considerations have convinced me that the important field of operations, around which all others should cluster, is that of increasing our membership, the most efficient and beneficial methods of doing which is therefore my principal topic. The highest member is the one who has as his object no personal advantage other than that of gratifying a desire to aid in the Association's work. Such people require no inducement, but their number is not great, so we must make it our business to provide all the inducements possible to secure members.

To shift this responsibility upon a membership committee is little short of fatuous. That committee can do very little unless its efforts are supplemented, or rather preceded, by numerous other influences in creating which all must unite. Our membership committee may be compared with an agent who books the orders for which the advertising
department has made wise preparations; with the president who awards diplomas to those who have been qualified to receive them; with the minister who baptizes the sinners who have been converted by the Salvation Army.

Probably the two most important attractions which we can offer are those of attendance at our annual meetings, and our publication of interesting and valuable information, regarding each of which I venture a few suggestions.

As to the former, it may be said that a small percentage of attendance at our annual meetings must be always looked for. It is doubtful if many members would absent themselves if they could—or felt that they could be present; this is certainly true of those who have ever attended the meetings; but conditions of time and expense must ever be expected to prevent a large majority from being present.

In just so far as we can remove these adverse conditions we can increase our attendance, so that even the humble question of transportation and hotel rates becomes well worthy of a place in the presidential address. I believe that on various occasions a more insistent course on the part of the committee of arrangements might have succeeded in securing better rates from the hotels that we have patronized. In other cases, accommodations equally as good in their essential features might have been secured by the selection of less expensive headquarters. It is always possible for those who desire it to stay at a more expensive hotel than that selected for the headquarters, but it is not so easy or agreeable to leave the headquarters' hotel for one that is less expensive.

It is especially desirable that there should be an increased attendance by the members of our families, and several possibilities for bringing this about suggest themselves. Perhaps the most important is that the headquarters' hotel should be induced to make a really liberal concession to additional members of a family occupying the same room. It does not admit of dispute that the additional expense of the occupation of a room by an additional person is quite trifling, and that a good hotel management should be ready to make concessions for securing an additional guest in this way, a concession which is of considerable importance to our members and to our meetings. It has, however, become a very common practice for hotel clerks to refuse such terms unless insisted upon. It would be well for future committees of arrangements to make a special feature of securing such rates and to insist upon them as one of the conditions of the contract. Such an arrangement would certainly tend to increase the attendance of our families, especially of those living near the meeting place, with great consequent advantages to the social features of our meetings.

It is not impossible, moreover, that some similar concession might be secured in transportation rates. May not the railroads be induced to offer a material reduction in rates to the wives and children of attending members? It would seem that the advantages to the roads of such increased attendance would amply justify such action, and it should not be difficult to devise a satisfactory plan by which the Association would become responsible for any abuse of the privilege by its members. It seems worth the while of our Committee on Transportation to endeavor to work out some such an arrangement with the railroad companies next year. Very likely this would require some general ruling by the federal commission, but this would only add to the value of the result.

This inherent difficulty regarding attendance at meetings has been most wisely met by the provision of local branches, at the meetings of which may be considered not only local subjects, but those relating to the general affairs of the Association. To encourage and support these branches, the Association should go to the limit of its possibilities. Undoubtedly the branches should ultimately become more than self-sustaining, and they should engage in a competition as to which can be most useful to the parent body; yet it seems certain that branches which would ultimately become important may be
unable to establish themselves except through the aid of the Association, and provisions for rendering such aid should be considered in advance. No other agency should be so effective in securing new members as that of the local branches. The committee having that subject in charge should select those localities where branches ought to be established, without regard to their present Association membership, and suit the method to the present respective conditions, institute a sustained line of effort that will not cease until the object is attained.

For the supplying of interesting and valuable information to our members, we have two agencies, the annual volume of Proceedings and the "Bulletin." Each performs a function, and an important one, that is impossible for the other; wherefores, I am not prepared to endorse the view of my predecessor, that one should replace the other. The history of success in all similar organizations is that they add one publication to another, but never abandon any. In my opinion, the "Bulletin" should be so conducted as to make it largely self-supporting through its outside subscription list. As its value increases and its subscription price is correspondingly raised, it would tend more and more to convert its subscribers into members. I recognize the danger of converting it into a competitor of the regular pharmaceutical journals, which are justly entitled to their subscription field without interference from us; yet it is clear to me that we could accomplish our object while rigidly restricting the "Bulletin" field to that of an Association organ, and thus reduce such objectionable competition to an insignificant minimum. In any case, we should allow no other consideration to restrain us from pursuing that policy toward the "Bulletin" which will make it most effective in building up our membership.

I therefore recommend that the most liberal policy that our circumstances permit be pursued toward the Bulletin, because (1) such a policy will ultimately yield a profit, from the Bulletin account alone; (2) there will result a bonus in the way of membership, which will tend toward a geometric increase.

This discussion should be supplemented by reference to the important relations between the Bulletin and the local branches. Every local branch should feel that it has a claim upon Bulletin space for everything of value that it can offer. Our editors, should, at the same time, be rigid in excluding anything that is not of sufficient value to reflect credit upon the Association. Let us never degenerate into a mutual admiration society, or seek support through the medium of flattery. It is quite possible, without yielding to such a tendency, to make our Bulletin a most powerful magnet for attracting membership to the branches, and thence to the parent body.

It is believed that the work of some of our committees, especially those on the Establishment of Local Branches, on Drug Reform, on Publicity and on National and State Legislation, should be organized on a more systematic basis, and conducted by more sustained methods. Very few of the subjects sought by these committees are likely to be accomplished in a single year. They mostly require persistent and long-continued effort, based on thorough investigation. The work of each year should be performed with a view to its continuation by the committee's successors, and these successors should thoroughly familiarize themselves with the plans under way and with the work that has already been performed. To facilitate this process, the committee should inaugurate a more systematic and formal method of performing their work, preserving a secretary's or chairman's minute-book, with the discussions and motions duly recorded in form for future consultation. Each retiring member should turn over to his successor all his copies of the preceding documents.

The obligations of the Committee on Local Branches have already been referred to. Those of the Committee on Drug Reform have been carefully studied, and the results submitted to its chairman. If this committee is to accomplish anything useful, it must have complete detailed information concerning existing evils relating to drugs and their
abuse. It must know what steps are necessary to correct them and to what extent such means are now being employed and how they should be supplemented. Here its results are taken up by the Committee on State and National Legislation, which should have on file all existing pharmacy statutes and all changes in them. It should have such general instructions from the Association as would enable it to act in influencing legislation, in at least many cases, without waiting for specific instructions. It should adopt some model law, and then endeavor to bring about as much uniformity as possible in national and state statutes, in line with this model. It is obvious that to accomplish such results its organization must be greatly changed. It should have sub-committees in every state for carrying on local work, and the members of these sub-committees should be those who are active in their respective state associations, so as to insure co-operation so far as may be possible, between these associations and ourselves. Provisions should be made for meeting such expenses of this committee as are inevitable in the performance of such important work.

The services of the Committee on Publicity will here be in demand. Our preceding discussion of the influence of the Bulletin demonstrates that without an outside subscription list such influence is chiefly restricted to our own membership, while even with it that influence will extend but little outside of pharmaceutical circles. Now a little consideration will make it clear that the progress for which we are striving must depend ultimately on the outside public. It is that public from which our profession derives its support, and it is axiomatic that any successful advertiser must reach the source whence his patronage is derived. All signs of the times point to the coming rule of the people in all things, in this country. It is inevitable that many mistakes must be made during the process, but it is through these mistakes alone that real progress can be made, and it is the basic principle of a democratic form of government that it secures public progress by casting responsibility upon the people. He is indeed a dullard who cannot see that our people are rapidly acquiring greater discretion, better judgment and more stability as a result of this responsibility. It is the wise course, indeed the only permanently successful one, to take the people into partnership, and the American Pharmaceutical Association can in no other way hope to accomplish good and lasting results in establishing a successful basis for professional pharmacy. In no other line of work does this principle apply so closely as in that of securing legislation. While the vestiges of ring rule will doubtless persist, this practice, as a dominating method of government, is dead, and there will be increasing difficulty in the future in enacting and maintaining any important legislation not first sanctioned by the people.

Upon these considerations depends the necessity of our maintenance of a genuine work of publicity, through the public press, and in other ways. My views on this subject have been communicated in detail to our present committee and some work has been already based upon them, an account of which will doubtless be submitted to you in regular course.

Much of the work of these committees, in order to produce useful results, necessitates expenditures of money, sometimes in considerable amount. To this my personal experience has borne eloquent testimony. During the last year I have pursued the policy of permitting no needed work to go undone through the want of any money that I could supply. The cost of this procedure has not been inconsiderable, notwithstanding that the work was purely of a preliminary character. What I know of the limitations in the past work of our committees convinces me that one of the chief causes of unsatisfactory results has been the want of necessary funds, although, as might naturally be expected, committees have not been free in publishing this fact. Something should certainly be done to correct this difficulty.

Doubtless many minds are now following me with the question, possibly sarcastic, "Where is the money to come from for carrying out the liberal financial policy that is
being recommended to us?" I have previously quoted our Treasurer as saying that our membership dues are not alone sufficient to support our present activities. I am convinced that some of the more important of the expenditures herein recommended will yield a cash profit after a time. In the meantime, where is the capital for the proposed investment? I reply, first, from the invested funds. I am not in favor of the policy of allowing the income of the Ebert bequest to accumulate until it reaches a fixed amount. If up to one fixed amount, then why not up to a greater one? On what basis are we to fix the limit to which the process of accumulation is to go? We need that income now more than we shall hereafter, and its increase, expended as I have suggested, will be greater than that which will result from compounding its interest. It has always been found that the best way for such bodies as ours to get more money is to judicially expend, in good work, all that they can afford of what they now have. It is not specially encouraging to a liberal policy on the part of those from whom we draw our income, to know that we have a considerable sum of money on interest and accumulating. It by no means follows that your President recommends that a point should be made of expending our income. The recommendation is rather a negative one, to the effect that, while we do in a general way favor the policy of accumulation, we should not refrain from any expenditure that is likely to do the Association more good than would result from the act of hoarding. The case of the Endowment Fund is quite a different one. There we have a fund originally established for a different purpose. To continue this process indefinitely, in relation to other funds; to establish a drain upon our membership wholly for the relief of those who come after us, is going too far in a good direction. It would be far more valuable to bequeath to our successors a well-organized and successful working policy, than any amount of cash in the treasury of a weak and inefficient organization.

There is, however, a much more efficient method of adding to our annual working funds, and one by no means difficult. This is the establishment of a new class of members, to be known as "Sustaining Members." Such members would be those voluntarily undertaking to pay into the treasury an annual fee in addition to that paid by ordinary members. They might be annual or life members, or those of any class whatever, who felt that they could afford such an annual contribution to our working funds. They should enjoy no special rights or privileges, and they should be free at any time, on notification to the Council, to retire from the proposed class. This plan has been found to work excellently in every society where I have seen it tried. There can be no question that there are many members of our Association who would not suffer at all from a contribution of ten dollars or more per year in addition to their regular dues. I believe, indeed, that if such a class of members were now organized, more than a hundred would be found just as soon as the fact became generally known. I, therefore, recommend that the Council be instructed to provide for such a class of members.

It is probable, and it is certainly to be hoped that our proceedings at this meeting will deal largely with pharmacopoeial matters. Indeed, it was with this hope and expectation that the date of the meeting was so changed as to bring it before that of the U. S. P. convention. In relation to this subject, our Association has a duty of high importance to perform in the interest of the citizens of this nation. It is not to be expected that any body of specialists will be equally well informed on all sides of so great a subject as that of the functions and influence of the Pharmacopoeia, and it is therefore the more important that each such body shall insist upon and stand for the recognition of those facts and principles of which, through its specially favorable position, it has knowledge, lest other bodies not in a similar position, should, through such specific ignorance, influence unwise action. As illustrations in point, I will remind you of some of the recommendations which have been published during recent months. One is that hydrastis should be dismissed from the Pharmacopoeia because it is not used to any ex-
tent. Another is that when two drugs have essentially the same action, one of them should be dismissed. The most typical case of this kind that could be suggested is that of veratum and aconite. Another is that when an active constituent fully represents the medicinal action of a drug, the latter should be dismissed. Probably the suggestion is meaningless, as there are no such cases, but if there are any, they would be found in nux vomica and strychnine, in aconite and aconitine, so that the suggestion calls for dismissing nux vomica and aconite and their preparations. Another is to reduce the number of preparations of a single drug. Although the idea here involved is not a bad one, the suggestion comes from sources which consider only the preference of a prescriber, and which wholly ignores the requirements that are made upon the practicing pharmacist. It is probable that all of the above suggestions will find strong support at the convention.

It is to be remembered that in this question concerning admissions to and deletions from the Pharmacopoeia, the real issue between physicians and pharmacists is the unwillingness of the former to permit the Pharmacopoeia to afford those provisions which are absolutely essential to the convenient, successful and safe performance of the pharmacist's duty, and to the welfare of great numbers of patients of those physicians whose practices in the selection of drugs differ from those of the objecting body. Let us deny to the more conservative element of the medical profession nothing that it asks in the performance of its proper functions. If it desires that the Pharmacopoeia should make a point of indicating in some emphatic manner which drugs and medicines have the approval of the wiser members of the profession, we will join hands with them in an attempt to secure such action; but let us unite in refusing any demands or requests which are based upon the assumption that our own interests are not entitled to proper consideration by them, or that any considerable number of people should be made to suffer a penalty because they chance to be the patients of less competent medical advisers. It therefore becomes our duty to express ourselves upon this subject, so that the Pharmacopoeia Committee may understand that we represent the belief and determination of our profession as a whole. I therefore direct your attention to a few fundamental facts and principles bearing on this subject.

1. It is a fact, perfectly well established by fifty years of official experience, that the admission to or the deletion from the Pharmacopoeia of an article has scarcely a perceptible influence upon the extent of its use. When dismissed from the Pharmacopoeia because the very best professional judgment regards it as therapeutically valueless, it will continue to be used as before, the only effect being to deprive pharmacists and their patrons of official standards for its control.

2. Many articles of little therapeutic activity, yet in common use, whether wisely or not, may, through their contained impurities, seriously affect the physical, chemical or therapeutical properties of prescriptions into which they enter, so that it becomes necessary for their purity to be safeguarded.

3. The primary object of the Pharmacopoeia is not to teach therapeutics, to influence therapeutical practice or to create an incorrect, however creditable impression regarding it, but to respond to the demands of such practice by providing suitable information and standards for rendering it as safe and efficient as the conditions permit.

4. All preceding revisions of the Pharmacopoeia have been based upon the declared principle that it is the actual use of an article that is to determine its recognition in the Pharmacopoeia, in spite of considerations as to its therapeutical merit.

It would be out of place in a presidential address to discuss Pharmacopoeial revision per se, and these suggestions are made in order to impress the importance of the duty of this Association to take definite action in applying that knowledge and judgment which especially pertain to it.

One more direction in which such duty applies may well be pointed out, namely, the
necessity for more definite standards. One of the most baneful possible conditions as to its power to cause errors of judgment, or to provide for unjust discrimination, or an accusation of it when it does not exist, is a want of definiteness in the expression of a standard. The Pharmacopoeia is now replete with defects of this class. Many of its definitions are absolutely meaningless and a larger number of its descriptions and directions are incapable of enabling a positive decision to be reached.

I therefore recommend that the Association reiterate, as its conviction, a statement found in the sixth revision of the Pharmacopoeia, and which has governed all subsequent revisions, that it is "best to refrain from dropping drugs and preparations which are, on inquiry, found to be in rather more than purely local use," also in another proposition, submitted by Professor Oldberg and adopted by the Committee of Revision in 1890, to the effect that the primary consideration in the recognition of a medicinal article by the Pharmacopoeia is the fact that it or its preparations is in common occurrence in the pharmacy, rather than consideration of its therapeutical importance or value.

That it is the opinion of this Association that the definitions, descriptions and tests of the Pharmacopoeia should be so fully and definitely stated as to insure as far as is practicable against misunderstanding or failure in interpretation by those employing the book.

It is doubtful if any subject has ever engaged the attention of this Association that is more complex and difficult, and yet of such far-reaching importance, as our relations to and attitude toward the National Formulary. Without introducing any discussion of the test of that work, reference may be made to a fact regarding which all will doubtless agree, that there is a peculiar danger that the influence of this work will be abused, and that the results of such abuse may widen instead of closing the breach between the two professions. If it shall appear to the medical fraternity that the professed campaign of the pharmaceutical profession against the abuse of nostrums is in reality only a concealed attempt to transfer this abuse, and in an exaggerated form, to other hands, it cannot be expected to, and should not, sympathize with it. It thus becomes highly important that the treatment of articles admitted to the Formulary be most carefully considered as to their influence upon medical practice, and upon the administration of the law. The legal recognition of the U. S. P. rests upon certain well-defined and securely established facts and principles. In its revision are directly represented, upon an absolutely equal footing, all branches of both professions, while to these are indirectly added all branches of theoretical and applied science which are contributory to the work of the two professions, and all state and national departments which have to do with the work of these professions. It is eminently proper that such a work should receive government recognition. On the other hand, without suggesting a criticism of the N. F. as to its character and origin, the very best that could possibly be said of it is that it emanates from one of these two professions only, and that it is wholly controlled by one of the organizations within that profession. It therefore does not rest upon the same broad foundation as does the U. S. P. and should not, by even the most liberal possible interpretation be accorded an equal standing. Be it noted again that this conclusion is not based upon any criticism of the work whatever, but upon the most favorable view that its best friends can take of it. To me it has become clear that if the N. F. is to retain its place as a legal and professional authority, its revision and control must be assumed by the same body that controls the Pharmacopoeia, and it must be given place as a supplement to that work. I hesitate to risk weakening the force of a conclusion thus based upon principle alone, by adding any discussion of matters of expediency; yet there are considerations of this character which are also of great weight. The public demands which have been made during the last year for the great extension of the range of the pharmacopoeia are of such a nature, and so powerful that they should not, cannot and will not be disregarded by the government of this country. One of two things will happen; either the two professions will yield to the demand, and devise a method tending most fully to con-
serve all interests, or one will be forced upon them that may show little regard for their special interests and views. Considerations of expediency, therefore, force us in the same direction as considerations of principle. This demand upon the Pharmacopœia Convention is incompatible with the views of an important element of the medical profession, and an important minority of the pharmaceutical profession, so that we see, with certainty, a conflict impending. The N. F., in the capacity of a supplement to the U. S. P., provides a perfect medium for acceding to this compelling demand without exacting any undue concession from those who oppose it. Therefore recommend that a committee, of which the Chairman of the Formulary Committee be a member, be appointed by the President immediately at the close of the reading of this address, to consider the desirability and the practicability of the publication of the National Formulary by the U. S. Pharmacopœia Convention, and, in case they approve, to submit to us before the close of this convention, a plan for bringing about the change recommended.

It may be added that such a disposition of the Formulary would not in any way prevent this Association from continuing to publish a work containing any articles the legal importance of which is not deemed by the U. S. P. Convention to be sufficient to justify their admission to either the Pharmacopœia or the Formulary.

Our Association should never lose sight of its relation to pure food and drug legislation and to the enforcement of its provisions after their enactment. We have wisely refrained from offering opinions or advice concerning the physiological properties of articles in dispute, feeling that, however strong the opinion which we entertained, we should be careful not to intrude upon the domain of the medical profession. Once a statute is enacted, however, our attitude is necessarily changed, for it is one of the solemn obligations upon which we have entered, to lend our aid in enforcing provisions thus established. Not alone are we interested in the provisions relating to drugs. A food and drug act is one entity, and its integrity in one part is dependent upon its integrity as a whole. It is the duty of this Association, and its appropriate committees should be so instructed, to observe and inquire into the administration of the Food and Drugs Act. It is a standing reproach against American citizens that they are in the habit of securing the enactment of statutes and then failing to take any interest in their enforcement. This is a reproach which should never be allowed to lie against the American Pharmaceutical Association.

I believe that one of the most important considerations to which we can devote attention in this connection, especially at a meeting which is held upon the eve of the assembling of the Pharmacopœia Convention, is the growing tendency of scientific experts to sell their services as witnesses without regard to the merits of the case or even the truth of the statements to which they are testifying. It is not a mere question of the commission of naked perjury; there are many ways of giving testimony outside of the witness-stand. The real offense is the sacrifice of that sense of responsibility to the cause for which all scientific effort should ultimately be put forth—the establishment of absolute truth. It is deplorable that so great and general a laxity in this direction should have come to exist. It is to such people as ourselves that the great uninformed body of the people look for an example of their own course of action, and the influence upon them of seeing us disregard our duty is ruinous to the public morals. What is to be expected from the students of an institution who see the professor to whom they look for an example go upon the witness-stand and, for a fee, swear to the exact opposite of that which he has been teaching them as the truth in his instruction course? Can it be expected that such influences will tend toward the training of pharmacists bent upon a conscientious discharge of their professional duties?

I do not know that any specific action by our organization toward amending this defect is possible, but it is quite practicable for us to keep it in mind whenever we are called upon to consider problems in which this influence enters as a factor.
The most serious danger which has ever threatened our profession now looms comparatively near at hand. I refer to the enlistment of vast amounts of capital in the crushing out of individual enterprise, in the elimination of professional responsibility, in the reduction of professional employees to a state of serfdom, and in the destruction of an honest means of livelihood on the part of great numbers of people engaged in pharmaceutical pursuits. That this attempt will become successful unless effectively opposed is manifest when we note that the same means are being employed which have already proven successful in other lines, and which are now applied to ours with the additional advantage of successful previous experience. The interests engaged in this work are the most deadly possible enemies of all the objects of our Association and of all other institutions in which educational and professional ideals are cultivated.

How shall we meet this stupendous danger? To this question I have been able to see but one answer and that is through the strength of union. We must in this instance fight fire with fire. While it is not appropriate for me at this time to discuss either the merits or demerits of the American Druggists' Syndicate, or to enter into any discussion of its past history, I feel that I should not refrain from directing your earnest and studious attention to the plan by which it proposes to fight this common danger. I am convinced that this plan, or some modification of it, is the only one which promises any hope of success. Without submitting any recommendation in the premises, I offer the opinion that it would be a most happy consummation to discover some satisfactory ground for a community of action, between two institutions whose interests harmonize in so many ways as do those of the A. Ph. A. and A. D. S.

The Association is to be congratulated upon the completion and publication of the National Pharmaceutical Syllabus, in the preparation of which it took an active and important part. Although this Syllabus is doubtless imperfect, and is to be regarded merely as the foundation stone of an important future structure, it must yet serve, even in its present condition, as a most important means for bringing about harmonious desire and effort, even if not at once harmonious action, between instructors and examiners.

In connection with the subject of education and legislation, I would direct your attention to the great desirability of the imposition of some educational and professional requirements, with a corresponding license, for engaging in commerce in drugs and medicines. If we go no farther than to institute a comparison between the extent of the danger of errors and offences committed in a wholesale way with those referring to the retail pharmacy, it would follow logically that there is a greater need of safeguards against the former than against the latter. The reasons, however, which appeal to us are of a far more definite and specific nature. It is unquestionably true that a vast majority of the collisions between importers and wholesale dealers in drugs and administrative officers of the government result directly from the ignorance of the former as to the nature and final effect of the imperfections in their stocks, of which the latter complain. Is it not the height of absurdity to assume that a dealer whose information regarding the nature, composition and properties of a drug, consists of little more than an accumulation of errors, would be likely to take a correct view of the proper requirements concerning such an article? As a matter of fact, it is an every-day occurrence for such dealers to submit requests, or more frequently to make demands, upon the authorities which are radically opposed to all professional interests in the article under consideration. It is my firm conviction, based upon a very long experience and a careful study of this subject in all its relations, that a special course in pharmacognosy, with a subsequent examination and license, should be required of every person having immediate charge of an importing or trading business in drugs and chemicals, and I recommend that our Committee on National and State Legislation be instructed to make suitable inquiry into this subject.
Our annual meetings should be made as attractive as possible. I have passed through the stage where I grudged the time taken from the working program for the social entertainment, and I have come to place a very high estimate upon the value of the latter as furthering the success of the former. The problem of providing fully for both has proved a difficult one, but I believe that it is solved, in principle, by the recommendation made last year by President Oldberg, looking toward the more extensive performance of work by the Council. A danger is here involved which must be thoroughly safeguarded. The Association should never lose its grip upon the proceedings of the Council. Whatever is done by the Council should be considered, and intelligently considered, by the Association, before being approved; yet it is possible to reach the best results in a vast majority of cases, in the transaction of business, by leaving the Council to perform the bulk of the work of study, discussion and deliberation.

A Council bearing these enlarged responsibilities should embody a pretty full representation of ex-presidents, and it seems to me desirable to renew a recommendation once made by President Whelpley that a retiring president should become, ex-officio, a member of the Council, either permanently or for a considerable period. Only one who has filled the office of president can comprehend the increased knowledge and enlarged view that the position must bring to him who makes any proper attempt to perform his duty. The presence in the Council of those who have thus been educated in the Association's affairs, cannot fail to be of the greatest value to us. Having myself already been elected to the Council for the ensuing three years, I am enabled to make this recommendation without the delicacy that might otherwise be felt.

In my use of the alphabetical list of members printed in the Proceedings, I have often been greatly embarrassed by my inability to find recorded the professional titles of the members. Ordinary rules of courtesy require that persons be addressed, especially in correspondence, by their appropriate titles, and it is very humiliating for an officer of the Association to be unable to ascertain how he ought to address his correspondent. Many years ago objections were made upon the floor of this Assembly to having members addressed by their titles. There was no concealment of the motives promoting the objection. Those who had no titles regarded it as invidious that others should be accorded them. The sentiment always appeared pitful to me, and I am happy in the belief that it finds few supporters in these more liberal times. Certainly such a restriction should not extend to a printed directory which is maintained solely for information and convenient reference. I therefore recommend that the Secretary be instructed, so far as he possesses the necessary information, to append to the names of members in our official directory, their proper academic and professional titles.

Hearty applause followed the reading of the President's address.

The Vice-President said that all had listened with a great deal of interest to this able and comprehensive address of the President. He asked whether it should be referred to a committee for consideration and report at a later session.

Mr. W. C. Anderson, of Brooklyn, moved that the recommendation of the President that a Committee be appointed by the Chair immediately after the close of the reading of the address, to consider the desirability and practicability of the publication of the National Formulary by the U. S. Pharmacopoeial Convention, be concurred in, and that the remainder of the address be referred to a committee of five, for consideration and report at a later session. This motion had a second in Mr. H. L. Taylor, of Albany, and the motion was put to vote and carried.
Under the motion as passed, Vice-President Lowe appointed the following as a Committee on President's Address: James H. Beal, of Scio, Ohio; Charles Holzhauer, of Newark, N. J.; Henry C. Blair, of Philadelphia; F. C. Godbold, of New Orleans, and Caswell A. Mayo, of New York. The Vice President stated that the President would appoint the Committee on National Formulary provided for under the resolution just adopted.

President Rusby resumed the chair.

The General Secretary said that he felt that he voiced the sentiment of the members present in offering a motion that he be instructed to send by wire the cordial fraternal greetings and best wishes of the officers and members of the American Pharmaceutical Association to Samuel A. D. Sheppard, of Boston; Charles E. Dohme, of Baltimore, and Oscar Oldberg, of Chicago, three prominent members who were prevented by illness from being present at the meeting to-day. President Rusby suggested that the name of F. J. Wulling, of Minnesota, be added to that list, for a telegram of condolence and sympathy, stating that Mr. Wulling had come to the Richmond meeting, but shortly after his arrival received telegraphic information announcing the death of his father. He said he felt sure Mr. Wulling would appreciate an expression from the Association under the circumstances. Mr. Henry M. Whelpley, of St. Louis, moved to add to the list for a telegram of kindly greeting the name of the venerable Enno Sander, of his city, Mr. Sander being the oldest living ex-president of the Association, and having recently celebrated his 88th birthday. Mr. R. H. Walker, of Texas, suggested the addition of the name of Doctor John B. Bond of Little Rock, Arkansas, who was reported quite sick. The motion of the Secretary as so amended was put to a vote and carried.

The President asked the Secretary if he had any other business to which to call the attention of the Association at this time, and the Secretary stated that it was in order now to call a list of the various standing and special committees as notice to their chairmen to have their reports ready by to-morrow morning's session for presentation and discussion. He thereupon called the following list of committees, with the names of their chairmen:

Committee on the U. S. Pharmacopæia—Geo. M. Beringer, Chairman.
Committee on National and State Legislation—Samuel L. Hilton, Chairman.
Committee on Transportation—Caswell A. Mayo, Chairman.
Committee on Time and Place of Next Meeting—T. W. Jones, Chairman.
Committee on Organization of Local Branches—Caswell A. Mayo, Chairman.
Committee on Pharmaceutical Collection at Washington—Murray Galt Motter, Chairman.
Committee on Reorganization—C. S. N. Hallberg, Chairman.
Committee on the William Procter, Jr., Monument Fund—John F. Hancock, Chairman.
Committee on Publicity—Francis B. Hays, Chairman.
General Committee on Membership and Reception—William B. Day, Chairman.
Committee on Patents and Trademarks—Thomas V. Wooten, Chairman.
Committee on the Bulletin—F. J. Wulling, Chairman.
Committee on Weights and Measures—Henry Kraemer, Chairman.
Committee on Status of Pharmacists in Government Service—George F. Payne, Chairman.
Committee on Parcels Post—W. S. Richardson, Chairman.
Committee on Drug Reform—L. E. Sayre, Chairman.
Committee on the Drug Market—E. L. Patch, Chairman.
Committee on the National Formulary—C. Lewis Diehl, Chairman.
Committee for Standard of Non-Official Drugs, Pharmaceutical Preparations and Chemical Products—Geo. M. Beringer, Chairman.
Delegates to the National Association of Retail Druggists—C. Lewis Diehl, Chairman.
Delegates to the National Wholesale Druggists' Association—Harvey W. Wiley, Chairman.
Delegates to the Section on Pharmacology of the American Medical Association—Jos. P. Remington, Chairman.

President Rusby here named the following as the Committee provided for upon the recommendation of the President's Address, to consider the desirability of the publication of the National Formulary by the U. S. Pharmacopoeial Convention: Joseph P. Remington, of Philadelphia; W. C. Anderson, of Brooklyn; George M. Beringer, of Camden, N. J.; C. Lewis Diehl, of Louisville; Lyman F. Kebler, of Washington City.

The Chair here gave opportunity to Mr. Beal, of Ohio, to submit some proposed amendments to the By-laws, to be voted on at the next session. Mr. Beal thereupon offered the following:

Amend Chapter X, Article I, line 1, by changing the word "ten" to "eleven;" insert after the sixth word, line 3 (members), the clause "a committee on the pharmaceutical syllabus of seven members."

Add Article XII, Chapter X, the Committee on the Pharmaceutical Syllabus shall be appointed by the President of the Association as follows: One member shall be appointed for seven years, and one for six, five, four, three, two and one years respectively; each vacancy occurring from expiration of term shall be filled for a term of seven years; other vacancies shall be filled at the annual meetings of the Association for the unexpired terms. This committee shall report to the Association through the Section on Pharmaceutical Legislation and Education, shall be members of the National Committee on the Pharmaceutical Syllabus and shall recommend to the Association its proportionate share of the current expenses.

Mr. Beal explained that the sole purport of these proposed amendments was to create a new committee of seven members, which should be known as the Committee on Pharmaceutical Syllabus, and to define the length of their terms, the manner of their appointment and their duties.

The Chair explained that this motion to change the By-Laws would, under the rule, have to go over to the next session for action.

The Chair then called on the Committee on Time and Place of Next Meeting for report, and explained that the acting Chairman of that Committee, Mr. Sayre, of Kansas, had reported to him that he was the only
member of the Committee present, and he had authorized him to complete the Committee by appointment from those present at this meeting. The report was not ready to be presented at this time.

The Chair then declared a recess of five minutes under the By-Laws, to give the members present from the various States and Territories an opportunity to select their representatives upon the Nominating Committee, now in order to be appointed. At the expiration of the recess, the Secretary called the roll of the various States, Territories, Island Possessions and Provinces of Canada, and the Nominating Committee was made up as follows:

For Arkansas—Wm. L. Dewoody.
For Colorado—S. L. Bresler, Chas. M. Ford.
For Florida—Ernest Berger, Wm. O. Richtmann.
For Georgia—Geo. F. Payne.
For Idaho—John Pulse.
For Illinois—Wm. Bodemann, C. S. N. Hallberg.
For Indiana—F. W. Meissner, E. G. Eberhardt.
For Iowa—W. F. Teeters.
For Kansas—M. Noll, L. E. Sayre.
For Louisiana—F. C. Godbold, Philip Asher.
For South Dakota—E. C. Bent, D. F. Jones.
For Tennessee—W. R. White, J. O. Burge.
For Texas—Miss V. Brookes, R. H. Walker.
For Maryland—J. F. Hancock, A. R. L. Dohme.
For Minnesota—W. A. Frost, A. D. Thompson.

For Missouri—J. M. Good, H. S. Merrill, Jr.
For Nebraska—Mrs. Belle Heilman.
For New Jersey—Chas. Holzhauer, E. B. Jones.
For New Mexico—A. J. Fischer.
For New York—Thos. P. Cook, O. Raubenheimer.
For Oklahoma—J. C. Burton, W. F. Dodd.
For Oregon—Geo. C. Blakeley, C. W. Huntley.
For Pennsylvania—J. L. Lemberger, John F. Patton.
For Vermont—W. F. Root, A. O. Austin.
For Virginia—A. G. Briggs, J. L. Avis.
For Washington—P. Jensen, C. W. Johnson.
For West Virginia—W. E. Dittmeyer, W. C. Price.
For Wisconsin—Otto Boberg.

There being no other business before the Association at this session, on motion of Mr. Payne, of Georgia, the Association stood adjourned until to-morrow (Wednesday) morning at 10 o’clock.

SECOND SESSION—TUESDAY AFTERNOON, MAY 3, 1910.

No business was transacted by the Association previous to the first sessions of the Section on Commercial Interests and the Section on Scientific papers.
MINUTES OF THE THIRD SESSION.

Third Session—Wednesday Morning, May 4, 1910.

The third general session was late in assembling, on account of a prolonged session of the Council, and was not called to order by President Rusby until 10:50 a.m., when the Secretary read the minutes of the first session, which the Chair stated would stand approved as read, without objection, and it was so ordered.

The Chair called for the report of the Nominating Committee as the next business in order, and Mr. Whelpley, of that Committee, presented the same as follows:

RICHMOND, VA., MAY 4, 1910.

To the Officers and Members of the A. Ph. A.:

The Nominating Committee met at 8:30 p.m., May 3rd, with fifty-three members present and nominated the following officers:

For First Vice-President—W. A. Frost, St. Paul, Minn.; Wilhelm Bodemann, Chicago, Ill.; George C. Blakeley, The Dalby, Oreg.

For Third Vice-President—Ernest Berger, Tampa, Fla.; J. O. Burge, Nashville, Tenn.; Chas. Holzhauer, Newark, N. J.

Respectfully submitted,

J. P. Remington, Chairman,
H. M. Whelpley, Secretary.

The Chair called for action upon the report of the Nominating Committee just read, and Mr. Cook, of New York, moved that the report be received and adopted as the sense of this Association. There were several seconds to this motion, and it was carried unanimously.

The Chair called for the reading of the minutes of the Council as the next order of business, and Mr. J. W. England, Secretary of the Council, read the minutes of the second session of that body, as follows:

Minutes of Council of A. Ph. A.

The second meeting of the Council of the American Pharmaceutical Association for 1909-10 was held May 2, 1910, at the Hotel Jefferson, Richmond, Va., at 3:30 p.m., Chairman Godbold presiding. Present: Messrs. Godbold, Koch, Whelpley, Eliel, Hallberg, Raubenheimer, Rusby, Chas. Caspari, Jr., C. E. Caspari, Asher, Bowman, Miller, Eberle, Wilbert, Motter, Diehl, LaWall, LaPierre, Johnson, Thomas, Meissner and England.

Chairman Godbold made the following opening address:

To the Members of the Council: After looking through the proceedings of the past five years, in search of an address made by one of my predecessors, and finding none, I concluded that it was not customary for the Chairman to make an annual address, and while I feel that I had something that I would like to say to the members, concluded to follow
the custom. Later, however, I read the following from Emerson, "Of no use are the men who study to do exactly as was done before, who can never understand that to-day is a new day."

I concluded that I would take advantage of the opportunity to say that when I was elected Chairman of the Council, I was so impressed with the drubbing that I would necessarily have to undergo, in being broken in as Chairman, that my whole thought was, how much I would have preferred that my opponent had been elected; and I so expressed myself at the time, neglecting to express my thanks to the members for the honor they had conferred upon me. So I want to say at this time that I fully appreciate the honor and the confidence implied by my selection as your Chairman, and I thank you all most heartily.

It has been very gratifying to me to note how promptly the members have voted upon the Council questions sent out in letters.

For a number of years I have thought it would be a good plan for the Association to issue a monthly journal, and I understand that the Committee on Bulletin of the Association has been considering the question, and while I do not wish to anticipate the report of the Committee, I want to call your attention to the subject, for I certainly feel that it would be of great value to our Association if we could have an official organ reporting, each month, on all interests of the Association. Whether it is practicable or not, at the present time, to do this, will doubtless be reported upon by the Committee on Bulletin.

Respectfully submitted,

F. C. GODBOLD.

Secretary England presented the following synopsis of the business transacted by the Council, by mail, since the last session held at Los Angeles, Cal., August 20, 1909:

Motion No. 10—That T. Ashby Miller, who served in a very satisfactory manner as Local Secretary for the 1909 meeting, be elected Local Secretary for the 1910 convention at Richmond; and also to be Chairman of the Committee on Arrangements, with power to appoint his associates.

Motion No. 11—That the Treasurer be authorized to invest five thousand dollars of the current funds in municipal or state bonds, the investment to be made on approval of the Committee on Finance and the Chairman of the Council.

Motion No. 12—That the By-Laws of the Association, relating to the number of sessions of the Section on Scientific Papers, be suspended, and that the Section be permitted to hold a sufficient number of adjourned sessions to consider and discuss all the communications that may be presented to it.

Motion No. 13—That the Committee on Publication be instructed to print in the volume of Proceedings each year, under the heading, "General Rules," all motions and resolutions adopted by the Council of the Association that remain in force for more than one year, but do not amend the Constitution, By-Laws nor Rules of Finance. The General Rules are to be printed on a page following the Rules of Finance.

Motion No. 14—That Jacob Jesson, of Ontario, Cal., on payment of $25.00, be made a life member, to receive the Proceedings.

Motion No. 15 (Committee on Invested, Savings and Trust Funds).

Whereas, The various permanent funds of the Association are mainly invested in public bonds which mature from time to time, thus necessitating reinvestment, and

Whereas, The Albert E. Ebert Legacy will shortly be paid into the treasury, and

Whereas, The investment of said permanent funds, legacy and other trust funds held by the Association should always be made with due caution, and only after careful deliberation, therefore be it moved by E. G. Eberle and seconded by M. G. Mutter that the following be adopted as Rules of Finance:

29
The Chairman of the Council is instructed to appoint three members of the Association who, together with the Treasurer, shall be known as the "Committee on Invested, Savings and Trust Funds."

Of the three members first appointed, one shall be appointed for one year, one for two years and one for three years. Each year thereafter, one member shall be appointed for three years.

Members of the committee need not be members of the Council.

It shall be the duty of the said committee to carefully consider the nature and status of all invested, savings and trust funds of the Association, and to make an annual written report upon the same to the Council, which report shall be read (in full) at one of the general sessions of the annual convention of the Association, and published in full in the annual "Proceedings" thereof.

The present custody of the funds shall not be affected by the adoption of these resolutions, neither shall the committee have power to invest or re-invest any of such funds, except as instructed by the Council or the Association.

Motion No. 16 (Election of New Members)—Applicants for membership Nos. 1 to 14 elected.

Prof. J. P. Remington advises the Secretary of the decease on October 7, 1909, of Prof. William M. Searby, of San Francisco, a member of the Council.

Resolutions on Death of W. M. Searby.

Whereas, The American Pharmaceutical Association has suffered a severe loss in the death of one of its most earnest and zealous members, Ex-President William Martin Searby, of San Francisco, Cal., therefore, be it

Resolved, That we place on record our deep appreciation of his sterling worth and unflinching honesty, and

Resolved, That we bear testimony to his able services on behalf of American Pharmaceutical Association, and

Resolved, That we mourn his demise as the loss of one whose work and worth as a man and fellow Pharmacist will live long in our memories.

The Chairman of the Council received a communication from C. Lewis Diehl, Chairman of the Committee on the National Formulary, regarding reports on work in National Formulary.

The Nominations of Committee Members, as made by the Chairman of the Council, approved by the Council members.

Motion No. 19. That Charles E. Whilden of 135 Stockton St., San Francisco, Cal., be nominated as a member of the Committee on Transportation to succeed W. M. Searby, deceased.

Motion No. 20. That the sum of Fifty Dollars ($50.00), be appropriated to cover the expense of the Committee on U. S. P., Geo. M. Beringer, Chairman.

Motion No. 21 (Election of New Members). Applicants for membership: Nos. 15-18 elected.

Motions Nos. 10 to 16, inclusive (Council Letter No. 1), all carried.

At the meeting of the Baltimore Branch, held October 21, 1909, John B. Thomas was elected to represent the branch in the Council, succeeding D. M. R. Culbreth.

Motion No. 22—That the time for holding the fifty-eighth annual meeting be changed from May 16-20, inclusive, to May 3-7, inclusive, which will give ample time for sightseeing in the city of Richmond and its surroundings on Sunday and Monday, May 8th and 9th, and to reach Washington, D. C., in time for the opening session of the United States Pharmacopœial Convention on Tuesday, May 10, 1910.
Motion No. 23—That a further appropriation of two hundred dollars ($200.00) be made for miscellaneous expenses for the current fiscal year.

The following communication has been received:

"The Committee appointed to nominate members for the Committee on Unofficial Standards reported as follows:

For the Term of One Year.

George M. Beringer, Camden, N. J. Chas. E. Caspary, Jr., St. Louis, Mo.

For the Term of Two Years.

H. P. Hynson, Baltimore, Md. Geo. B. Kauffman, Columbus, Ohio.

For the Term of Three Years.

For the Term of Four Years.

The Committee further nominates George M. Beringer for Chairman of the Committee on Unofficial Standards.

It is further recommended that the Nominating Committee be continued and empowered to present nominees to any vacancies in the above list caused by the refusal of any of those named to serve.

J. H. Beal,
J. A. Koch,
Philip Asher,
Committee.

Motion No. 24—That the above report be accepted and the recommendations agreed to.

Motions 17 to 21, inclusive (Council Letter No. 2), all carried.

The Council is advised under date of November 8, 1909, that Frederick J. Wulling, of Minneapolis, has been re-elected as a member of the Council to represent the Northwestern Branch.

Chairman Godbold announced that in accordance with Motion No. 15 (Council Letter No. 1) he appointed the following "Committee on Invested, Savings and Trust Funds": J. H. Beal (three-year term), Chairman; Thomas P. Cook (two-year term) and Treas. H. M. Whelpley, ex-officio (one-year term).

Motion No. 22—Providing that the time of holding the fifty-eighth annual meeting be changed from May 16-20, 1910, inclusive, to May 3-7, 1910, inclusive, carried by a large majority, only two votes being negative.

Motion Nos. 23 and 24 have carried also.

Chairman Godbold has appointed E. G. Eberle as the member for the one-year term of the Committee on Invested, Savings and Trust Funds. The other members of the Committee (Council Letter No. 3) are J. H. Beal (three-year term), Chairman; Thomas P. Cook (two-year term), and Treasurer H. M. Whelpley, ex-officio.

The nominations as made under Motion No. 24 (Council Letter No. 23) having been approved, the following motion is offered:

Motion No. 25—Do you vote for the Committee on Unofficial Standards as nominated?
H. P. Hynson declines nomination for Committee on Unofficial Standards; name withdrawn.

Motion No. 26 (Election of New Members)—Applicants for membership from 19 to 28 elected.

Treasurer Whelpley writes under date of November 5, 1909, that the St. Louis Branch is not doing sufficient work to be entitled to a Council member. Therefore, erase name of Otto F. Claus from list of A. Ph. A. Council members for 1909-1910.

Motions Nos. 25 and 26 have carried.

Chairman C. H. LaWall, of the Committee on Pharmaceutical Education and Legislation, has named John C. Wallace, of Newcastle, Pa., as a member of the Committee on Opium Legislation, to take the place of H. P. Hynson, of Baltimore, Md. (who has declined to serve), and Lyman F. Kebler, of Washington, D. C., to succeed the late Mahlon N. Kline, of Philadelphia; this was subsequently approved through Motion No. 27.

Treasurer Henry M. Whelpley has, in accordance with Motion No. 11, Letter No. 1 (October 12, 1909), and on "approval of Committee on Finance and of the Chairman of the Council," invested $5,000.00 current funds in bonds. The purchase was made on November 15th from A. G. Edwards & Sons, of St. Louis, of one registered St. Louis City Public Buildings and Public Works, Registered 4% Gold Bond, No. 717, due July 1, 1928, at $101½, netting about 3.90 per cent. interest. This amounted to $5,075.00, with $74.44 interest, making a total of $5,149.44. The bond is in the name of the American Pharmaceutical Association and placed in the Association's safe deposit box. This was approved through:

Motion No. 28 (Approval of Investment of Current Funds in Bond).

Motion No. 29—That the sum of $25.00 be appropriated to pay the additional premium on the treasurer's bond.

This additional appropriation is made necessary by the fact that at the last annual meeting the bond of the Treasurer was increased from $5,000.00 to $15,000.00, while the budget of appropriations adopted at Los Angeles covered but $12.50 for the premium, which latter under the present conditions amounts to $37.50.

A safe deposit box for the Treasurer has been provided.

The General Secretary, the Local Secretary, and the Secretary of the Council, submit program to the Council for consideration.

Motion No. 30—Applicants for membership Nos. 29 to 54 elected.

Motions Nos. 27, 28, 29, and 30 (Council Letter No. 5) have carried.

Permission is asked by the National Association of Retail Druggists to use for comment parts of the text of the National Formulary in an edition of "The Modern Pharmacist" (which the organization is about to issue), as per specimen of formula in abstract submitted.

Motion No. 31—That permission be granted to the National Association of Retail Druggists to use the text of the National Formulary in abstract form in "The Modern Pharmacist," as submitted in application, such permission for similar form having been already granted to the American Medical Association, the U. S. Dispensatory, the National Standard Dispensatory, and others.

To the Chairman and Council: Thomas P. Cook, of New York City, nominated to fill the vacancy on the Committee on Unofficial Standards occasioned by the resignation of Henry P. Hynson by Nominating Committee of J. H. Beal, J. A. Koch, Philip Asher.

Motion No. 32—Do you approve the nomination and elect Thomas P. Cook to succeed Henry P. Hynson as a member of the Committee on Unofficial Standards?
Communication from Chairman Godbold presented to the members of the Council that
the Chairman had received a letter from Prof. C. Lewis Diehl, Chairman of the Commit-
tee on National Formulary, to the effect that the work is progressing, and that if it is
not interfered with, he has reason to hope that a final report can be presented at the
annual meeting in Richmond.

Motion No. 33—Applicants for membership Nos. 55 to 80 elected.

Motions Nos. 32, 33 and 34 (Council Letter No. 6, p. 13), have carried.
Communication received from Otto Raubenheimer relating to Motion No. 31, against
giving permission to the National Association of Retail Druggists to use, for comment,
parts of the text of the National Formulary in an edition of the “Modern Pharmacist”
(which the organization is about to issue).

George P. Hitchcock made a protest, also, to the Secretary of the Council, against
Motion No. 31, asking that the motion be withdrawn.
This the mover of the motion declines to do.

George M. Beringer votes yes on Motion No. 31, with the suggestion that only ap-
proved formulas be abstracted.

Under date of January 27, 1910, the Secretary of the Council is advised by Secretary
Day of the Chicago Branch of the A. Ph. A., that at the annual election held on the 25th,
the Chicago Branch elected C. A. Storer, Rush and Ohio Streets, Chicago, Ill., repre-
sentative of the Branch in the Council of the American Pharmaceutical Association.
The Chairman of the Committee on Bulletin submits a report on the additional
expense growing out of the publication of the N. F. Reports in it, and urges that an
additionaal appropriation be made to meet the exigencies of the case, and that it be
paid out of the National Formulary Fund.

In this connection a statement was submitted by the editor suggesting that:
(1) The “Bulletin” for March, April and May be limited to 32 pages, in which case
much of the Branch proceedings will have to be omitted, or
(2) To ask the Council that the entire appropriation, $2,000.00, be allowed for the
nine months of the “Bulletin” instead of twelve months, as intended by the Council
when made at the annual meeting.

Motion No. 35—That as much as may be required of the two thousand dollars that
have been appropriated for the “Bulletin” for the ensuing year be expended for the
“Bulletin” up to and including May, 1910.

“That will relieve the Council of the immediate necessity of allowing an additional
sum. The expenses of the “Bulletins” after May may be taken into consideration
together with the recommendations that the Committee on Bulletin proposes to make
to the Council at the Richmond meeting.”

Motion No. 36—Applicants for membership Nos. 81 to 91 elected.

The Committee on Invested and Trust Funds of the Association submits the following
recommendations:
(1) That the money received from the Ebert Legacy be kept separate from the present
Ebert Fund, and converted into a fund to be known as the “Ebert Legacy Fund.”
(2) That the Ebert Legacy Fund be invested in municipal or other public bonds ap-
proved by the Committee on Invested Funds and the Finance Committee, and that it be
kept intact and the income added thereto until the fund and its accumulations shall
together amount to a total of $10,000.
(3) That after reaching that sum the income derived from the fund shall be devoted
to such purposes as will, in the opinion of the Council, best commemorate the founder
of the fund and his services to pharmacy.
(4) That until such a fund has been established by the Council the receipts from the Ebert Legacy shall be deposited by the Treasurer in the International Bank of St. Louis, or other St. Louis bank, upon interest-drawing certificate or account.

(5) That the name of the present "Ebert Fund" be changed to the "Ebert Prize Fund," and that the Ebert Prize of $25.00 be continued upon the same terms as heretofore. Any excess of interest above the amount awarded in prizes shall be added to the principal until the same shall amount to $1,000.00, after which the entire annual interest upon the same shall constitute the "Ebert Prize."

The reason for the committee's suggestion that the old Ebert Fund and the Ebert Legacy be kept separate is, that the first was given by Mr. Ebert for a specific purpose, while the latter was given to the Association practically without restriction and with the evident intention that the Association should use it in the manner which it deemed best. It is evident that if the Ebert Legacy be added to the present Ebert Fund the rules covering the latter would apply to the whole, while the income would be much greater than was intended by the donor as a prize for the character of paper specified in the donation.

In case the preceding recommendations are agreed to by the Council, the committee recommends:

(6) That the Committee on Finance be authorized to invest all of the foregoing funds and also the General Endowment Fund of the Association in bonds of the city of Cairo, Illinois, to net 5 per cent. income or better, or in other municipal bonds of the same grade and amount of income return.

Such an investment would increase the net return over that now received from the aforesaid funds to the extent of not less than 25 per cent. annually.

(7) That we recommend to the Council and Association (at the next annual convention) the making of such changes in Article four of the Constitution as will permit the investment of the Life Membership Fund in municipal or other public bonds, as well as in Federal and State Bonds.

(8) We recommend that the Procter Monument Fund, of which the A. Ph. A. is trustee, be continued on interest-drawing deposit with the International Bank of St. Louis.

J. H. BEAL,
THOS. P. COOK,
E. G. EBERLE,
H. M. WHELPLEY.
Committee.

Communication received from C. Lewis Drehl, Chairman of the Committee on National Formulary, reciting the methods of communication to the sub-committees and members of the Committee through the Bulletin and personal correspondence.

With the assistance of Mr. Wilbert, the circulation of correspondence with the members by means of mimeograph circulars, of which a sufficient number is to be mailed to the members of the Committee has recently been adopted. This circular, designated as "Bulletin of the Committee on National Formulary," is to be issued semi-monthly, and as much oftener as exigency requires.

The expense will be very light, and since it will not increase the cost very materially, if any, it is suggested therefore, that a preliminary appropriation of $50.00 be made by the Council for preparing and issuing a Bulletin of the Committee on N. F., in mimeograph as above explained.

Such appropriation to be made from the fund accruing from the profits on the sale of the N. F.

Motion No. 31 (Permission to use parts of National Formulary in the "Modern Pharmacist" as per specimen formulas in abstract submitted) being still pending, a number of communications upon it were received, protesting against any use of such text as would interfere with the sale of the book.

No action has been taken on the program for the fifty-eighth annual meeting (1910) at Richmond, Va., submitted in Council Letter No. 5, and the General Secretary, the Local Secretary and the Secretary of the Council offer a revised program, as a substitute.

Motion No. 37—The program as modified will appear in the notice of the annual meeting.

Letter received from C. Lewis Diehl, Chairman of Committee on N. F., on resignation of Henry P. Hynson from the Committee on National Formulary.

Letter received from Francis B. Hays, Chairman of the Committee on Publicity of the American Pharmaceutical Association.

Associated Press representative at the Richmond meeting.

Motion No. 38 (Election of Members)—Applicants for membership Nos. 92 to 108 elected.

Motion No. 39—that the By-Laws of the Association relating to the number of sessions of the Section in Practical Pharmacy and Dispensing be suspended, and that the Section be permitted to hold a sufficient number of adjourned sessions to consider and discuss all the communications that may be presented.

The chief object of the motion being to obtain sufficient time to hold a "Symposium on the Pharmacopeias of the World" on Friday evening, May 6, 1910.

Motion No. 40—that Friday, May 6th, 9 a.m., be designated as the time for the reorganization of the Council, and that this information be inserted in the regular program for the Richmond meeting.

Motion No. 41—that the Council make an appropriation of $50.00 to the Committee on N. F. for the expense of issuing bulletins to the members of the Committee.

Communication received from G. M. Beringer moving that the Council do not accept the resignation of Professor Henry P. Hynson as a member of the N. F. Committee.

Motions Nos. 35 and 36 (Council Letter Nos. 7, 18), 37 and 38 (Council Letter Nos. 10, 21 and 23), 39, 40 (Council Letter Nos. 11, 24), have all carried.

The vote on Motion No. 31 (Council Letter Nos. 6, 13) granting permission to use parts of the National Formulary for comment in "The Modern Pharmacist" has carried by a majority vote.

Communication received from Otto Rauhenheimer on resignation of Professor Hynson as a member of the N. F. Committee.

Motion No. 42—that the Council do not accept the resignation of H. P. Hynson as a member of the Committee on National Formulary.

Motion No. 43—that the recommendations of the Committee on Invested and Trust Funds be adopted.

Motion No. 44—Applicants for membership Nos. 109 to 116 elected.

Motions Nos. 42, 43 and 44 have carried.

Communication presented from Chairman Godbold on resignation of H. M. Whelpley as a member of the Committee on the Reimbursement of George M. Beringer; also letter from H. M. Whelpley, resigning.
Motion No. 45—That the resignation of H. M. Whelpley as a member of the Committee on Reimbursement of George M. Beringer be accepted.

Motion No. 46—That the membership of the Committee on Reimbursement of George M. Beringer be increased from three to five in number, and that the Chairman of the Council be authorized to appoint three members on the committee to act with the remaining members.

Motion No. 47—That $20.00 be appropriated to cover expense of certificates of membership on parchment.

Motion No. 48—Applicants for membership Nos. 117 to 129 elected.

Motion No. 41 has carried, the proposed expenditure having been approved by the Finance Committee.

Motions Nos. 45, 46, 47 and 48 have carried.

In accordance with Motion No. 46, Chairman Godbold has appointed the following as the three additional members on the Committee on Reimbursement of George M. Beringer: J. F. Beal, E. G. Eberle and J. L. Lemberger, to act with the two previous members, H. H. Rusby and M. I. Wilbert. The appointments have all been accepted.

Motion No. 49—That the General Secretary be instructed to have thirty gold badges made, and also forty gold bars, for the Richmond meeting.

Communication received from Henry Kraemer asking that Prof. Arthur Meyer, of Marburg University, be elected an honorary member of the American Pharmaceutical Association.

Motion No. 50—Applicants for membership Nos. 130 to 158 elected.

Mr. England next read the minutes of the third session of the Council, held at Richmond, on Tuesday morning, May 3, 1910.

Minutes of the Third Session of the Council.

The third meeting of the Council for 1909–10 was held May 3, 1910, at 9 a. m., Chairman Godbold presiding. Present: Messrs. Godbold, C. Caspari, Jr., Eberle, Whelpley, C. E. Caspari, Asher, Johnson, Day, Lowe, Raubenheimer, Motter, Koch, England and Bowman. The minutes of the previous meeting were read and approved.

Applicants for membership Nos. 196 to 205, inclusive, were elected.

Charles Caspari, Jr., reported for the Committee on Publication on the subject of a Decennial Index.

Mr. Whelpley moved, seconded by Mr. Wilbert, that the next Decennial Index cover volumes 51 to 60, inclusive. Carried.

The Committee on Revision of Mailing List of the Proceedings reported progress.

The request of Henry Kraemer (contained in Council Letter No. 14) that Prof. Arthur Meyer, of Marburg University, be made an honorary member of the Association was, on motion of Mr. Wilbert, seconded by Mr. Rusby, agreed to, and Prof. Meyer was elected.

On motion of Charles Caspari, Jr., seconded by Mr. Motter, Prof. Alexander Tschirch, of Berne, Switzerland, was elected an honorary member of the Association.

Mr. Remington read a communication addressed to William H. Taft, President of the United States, inviting him in the name of the American Pharmaceutical Association, to be present at the opening of the U. S. Pharmacopoeial Convention, on May 10, 1910, at Washington, D. C. The sending of the communication was approved.

The annual report of the Secretary of the Council was presented and accepted. It was as follows:

To the Chairman and Members of the Council:

The Council of 1908–09 held six sessions in Los Angeles last year. The Council of 1909–10 held one session and an adjourned session, and has transacted business by mail since the Los Angeles meeting.
Fourteen Council Letters have been issued, covering 32 pages and conveying 50 motions.

The members elected during the year, to date, number 195, with no applicants rejected. This number is less than last year (379), but there have been only about six months since the Los Angeles meeting.

A synopsis of the minutes of the Council will be submitted, and become a part of the published records. The minutes have been published in the Bulletin.

The membership of the Council now numbers 35; of these 12 are members from branches.

Respectfully submitted,

Motions Nos. 49 and 50 (contained in Council Letter No. 14) were reported as having passed.

Applicants for membership Nos. 159 to 195, inclusive, were elected.

Moved by Charles Caspari, Jr., that the Committee on Membership be requested to submit all names of applicants for membership to the respective state representative on the Committee for approval before sending the applications to the Secretary of the Committee on Membership for submission to the vote of Council, or if they be sent direct to the Secretary of the Committee on Membership they shall be sent by him, first, to the state representative, for approval. Seconded by Mr. Wilbert. Carried.

Moved by Mr. Whelpley, seconded by Mr. LaWall, that the above motion be made a General Rule and published in the Proceedings.

Moved by Mr. Whelpley, seconded by Mr. Koch, that the following resolution be made a General Rule: “The resignation of a member may be accepted during the first six months of the fiscal year for which his annual dues are payable.”

Application was made by J. O. Burge, Nashville, Tenn., for permission to form a Nashville Branch of the A. Ph. A. Permission was granted on motion of Mr. Whelpley, seconded by Mr. Raubenheimer. Mr. Burge presented applications for membership from 21 new members, which together with 10 older members, makes the Nashville Branch number 31 members. The list is as follows:

List of members of Nashville Branch of A. Ph. A.:

E. A. Ruddiman, Max Bloomstein, Ernest John Schott,
J. T. McGill, Lucius Polk Brown, Frank Leslie Smith,
E. F. Trolinger, Moses Cook, Clarence Caery Young,
W. R. White, Lucius Junius Desha, Billie Calvin Wright,
Ira B. Clark, Myer Ernest Hutton, David Harold Zbinden,
R. L. Eves, David Jacob Kuhn, Wm. Marshall Blackman,
L. H. Holt, Jr., Andrew Joseph Martin, W. Benson Rippetoe,
D. H. Neil, James David McGinnis, Jerome Bonaparte Sand,
J. O. Burge, Stephen William Moore, Harold Felix Zbinden,
George T. Wilson, Luther Smith Pully,
Kenley Glass Austin, Roy Rascoe,

On motion of Mr. Rusby, seconded by Mr. Hallberg, a rising vote of thanks was passed to Mr. Burge for his work in the formation of the Nashville Branch.

On motion of Mr. Hallberg, seconded by Mr. England, William R. White, who has been selected by the Nashville Branch to be Council member, was given the privileges of the floor.

Mr. Eberle reported progress for the Committee on Mexican Membership.

On motion of Mr. Koch, seconded by Mr. Hallberg, the committee was continued.

The Committee on Credentials was appointed by Chairman Godbold, consisting of Messrs. Koch, Johnson and Asher.
The report of the Committee on Publication was presented by Chairman Caspari, as follows:

**Report of Committee on Publication.**

Your Committee on Publication beg leave to report that the "Proceedings" of the fifty-seventh annual meeting have been published, and a copy of the same delivered in March of the present year, and since that time to every member entitled thereto, according to the Treasurer's accounts, besides the usual number (about 100) of complimentary copies to the honorary members, state libraries, the pharmaceutical press, educational institutions and foreign bodies. Of the total number of books (2,400) printed, 350 copies remain on hand in flat sheets, 2,000 having been bound in cloth and 50 in paper. It was also found necessary during the year to bind in cloth 75 copies of the 1907 volume and 150 copies of the 1908 volume of Proceedings, the stock having become exhausted and demand arising for the same. The cost of publication and delivery for the nine months, July, 1909, to May, 1910, is shown by the following items:

**Total** $5,260 54

For the Committee, Chas. Caspari, Jr., Chairman.

Baltimore, May 2, 1910.

The report was accepted.

General Secretary Caspari reported an opinion by Gans & Haman, of Baltimore, on the legal liability of the Association, if any, should it reimburse G. M. Beringer for the expense of the suit against him by the "Farbenfabriken" of Elberfeld Company. The opinion reads as follows:

*The American Pharmaceutical Association:*

At the request of your Secretary, Charles Caspari, we have given consideration to the question whether, if your society reimburses George M. Beringer, of Camden, N. J., in whole or in part for the expenses incurred by him in the suit against him by the "Farbenfabriken" of Elberfeld Company, it will thereby render itself liable to a suit by the "Farbenfabriken" Company. The suit referred to was for libel and slander by the "Farbenfabriken" Company against Mr. Beringer, based on the reading by him before the Association at its fifty-third annual meeting held in September, 1905, of a paper entitled "Why the Mann Bill should be Enacted," followed by a publication of the paper in the volume entitled, "Proceedings of the American Pharmaceutical Association, 1905, Volume 53." We have read the article referred to and also the opinion of the United States Circuit Court of Appeals for the Third Circuit, which affirmed a judgment of the Circuit Court of the United States for the District of New Jersey in favor of Mr. Beringer.
The opinion is reported in Volume 158, "Federal Reporter," page 802. We have also read the certificate of incorporation of your Association, and note its corporative purposes. We further understand that it is an Association not organized for profit and not conducting any profitable business, having no capital stock and having a revenue derived principally from dues paid by members.

As a result of our consideration of the matter we are quite clearly of the opinion that your company will not incur any liability to the "Farbenfabriken" Company by making the payment proposed. The entirely sufficient reason for this opinion is that the contribution you are asked to make is for the defense of a suit by Mr. Beringer in which it was finally determined that the plaintiffs had no cause of action against him, because the publication referred to did not constitute a libel upon the plaintiff. The result of the case, to the expense of which you may possibly decide to contribute, was a judicial determination that there was no libel committed against the plaintiff. By making the contribution a non-libelous article could not be converted into a libelous one.

Even if the article could be considered a libel upon the "Farbenfabriken" Company, still we do not think that the contribution you are asked to make would make your Association any more liable to the "Farbenfabriken" Company than it now is by reason of the publication of the paper among your proceedings. The paper was prepared by Mr. Beringer at the request of your Association, and published in due course among the proceedings. According to the practice of your body, we understand that papers when read before the Association can either be repudiated or vetoed, or allowed to take their usual course, which means, as we understand, their publication. In this case we understand the paper was allowed to take its usual course and published. If the article had been libelous, as a matter of law your Association would have been civilly liable by the reason of its publication. The payment of Mr. Beringer's expenses would have no importance with regard to determining the question of your liability, except by way of a ratification by your Association of his statements.

This, however, is not an important consideration in the present case, where you have already adopted his statement by publishing the same among your proceedings. We do not mean by this expression that your body is necessarily committed to the views expressed by Mr. Beringer in his paper, but it is a familiar rule of the law of libel, that one who spreads a slanderous or libelous publication is civilly liable, even though he does not originate it. In this case, therefore, if the article had been libelous, its publication by your Association would have established your responsibility, which would not be legally increased by making the payment to Mr. Beringer, except in so far as this might be an additional consideration for a jury in estimating the damages.

We appreciate that it is possible that the "Farbenfabriken" Company might still proceed against your Association for the publication of this paper, and contend that the decision in its suit against Mr. Beringer would not be conclusive in its suit against the Society, because the proceedings are between different parties, and for that reason the first case would not constitute an absolute legal bar to the prosecution of the second. But if such a suit were brought it would have to be based upon the publication of the article by you in the first place, and not upon your contribution to Mr. Beringer's expenses.

In our examination of the question submitted by Dr. Caspary, we have given consideration to one or two other matters which may be of interest to you, although they are not necessarily involved in the decision of the particular question.

The points that we have in mind are, whether your Association is civilly liable at all for the publication of any paper which may be read before it, provided the publication is made in good faith and without malice. There is some authority in favor of the proposition that such a publication is of a privileged character, but we do not think that the cases have been sufficiently numerous to be decisive on this point. Another question that we had in mind was whether an Association such as yours can be made civilly liable at all in an action for a wrong.
MINUTES OF THE THIRD SESSION.

There is a well-known doctrine of the law that charitable associations, such for instance as hospitals, cannot be successfully sued at all for torts. The reasoning in support of some of the decisions to this effect is perhaps broad enough to include in this exemption many other classes of organizations which are not organized or conducted for profit. The extent of the application of the doctrine is, however, uncertain. It has been applied in Maryland to the House of Refuge, to a county school board and on several occasions in the city courts to the Johns Hopkins Hospital. We are not able to say that this doctrine of exemption from liability could successfully be invoked by your Association, although the question will be an interesting one of law if it should arise. It is, perhaps, of not much practical importance to you in view of the fact that if the Association were not civilly liable for a publication such as we mention, doubtless the officers of the Association who participated in the publication would be personally liable.

At the request of your Secretary, we are enclosing our bill for services in this matter.

Yours very truly,

GANS & HAMAN.

Baltimore, November 13, 1909.

On motion of Mr. Eberle, seconded by Mr. Whelpley, the report was accepted.

Treasurer Whelpley reported that he had prepared a statement as Treasurer for the period to April 1, 1910. He would prepare, later, a report to the end of the fiscal year, June 30, 1910.

On motion of Mr. England, seconded by Mr. Koch, the Auditing Committee was directed to audit the Treasurer's report for the fiscal year to June 30, 1910.

Treasurer Whelpley made an explanation with reference to a bill of H. D. Knisely for $32.40 for Committee expenses. The bill was approved by the Committee on Finance, and ordered paid.

Mr. Rusby, seconded by Mr. Meissner, moved that whenever an appropriation was made by the Council, the Secretary of the Council should notify the parties who were to expend the appropriation, as well as the Chairman of the Committee on Finance.

moved by Mr. LaWall, seconded by Mr. Whelpley, that the above resolution be made a General Rule and published in the "Proceedings."

Communication was received from Dr. V. E. Wiechmann, of Lawrence, Mass., asking for permission to publish the National Formulary in the Italian language.

On motion of Mr. Hallberg, seconded by Mr. England, the request was referred to the Committee on National Formulary to report back to the Council.

Chairman Meissner, of the Committee on Finance, suggested that before bills are sent to the Committee on Finance they should be first approved by the party contracting them, and marked by the name of the items to which they should be charged.

Editor Hallberg presented the report on the "Bulletin," as follows:

REPORT ON THE BULLETIN BY THE EDITOR.

Expenditure monthly from September, 1909, to May, 1910, inclusive:

Total: $1,725.50
The Council voted at the last annual meeting that the "Bulletin" may be increased from 32 to 48 pages, as required, to more completely report the Branch meetings and other Association activities, and appr-priated $2,000 to defray such expenses for the year, including the $200 salary of the editor.

The September "Bulletin" consisted of 48 pages, devoted chiefly to a report and review of the annual meeting. The publication of the Report of the Committee on the National Formulary required an increase to 64 pages for the October "Bulletin," as did the report of the Committee on the U. S. Pharmacopeia also require 64 pages for the November "Bulletin;" the December "Bulletin" was 48 pages.

The publication of these reports having consumed considerable space required that most of the "Bulletins" after the first of the year would have to be kept within the original limit of 32 pages, so as not to exceed the average of $150 per month appropriated. Since this would have been a sore disappointment in that the program of devoting more pages to the Branch reports would have to be largely abandoned, the Committee on the Bulletin asked the Council to permit as much of the appropriation for the year to apply to the nine months, intervening the annual meetings this year, which the Council promptly granted. The result was the increased monthly allowance of $200 instead of $150, sufficient to defray the expenses of a 64-page "Bulletin" for the five months remaining to this meeting.

As will be seen the expenditures for these nine months amounts to $1,725.50, averaging little less than $200 per month, owing to the fact that two "Bulletins" contained 48 pages. The editor's salary adds $124 for the period of nine months, thus making a total of $1,850, leaving a balance of $150 within the limit of the appropriation.

The "Bulletin," particularly during the past five months, has tried to give the fullest reports of the Branch meetings, and when possible also has published many papers read at those meetings. It has also endeavored to present such reports, resolutions, etc., from the annual proceedings as would be desirable for reference to members actively engaged in Association work without awaiting their publication in the annual volume.

It is believed that this feature is appreciated and should be continued and extended.

The work of the Association will always be hampered and delayed unless those interested are furnished promptly with complete information on the many subjects considered at the annual meetings in order that they may continue the work intelligently and promptly.

There are a great many other features which suggest the advantages of an extended and enlarged "Bulletin."

This, however, is a subject which the Committee on the "Bulletin" will no doubt bring to your attention.

The editor has endeavored as far as his time permits to make the "Bulletin" useful to the Association, and has made the May "Bulletin" a complete program for the annual meeting, as well as our affiliated Associations, the Conference of Faculties, the National Association of Pharmacy Boards and the United States Pharmacopeial Convention.

In the hope that his efforts may have been of service in creating more interest in the Association and in its work and increasing the membership, this report is respectfully submitted.

C. S. N. HALLBERG, The Editor.

Chicago, April 30, 1910.

The resolution of Mr. Whelpley, passed at the meeting of the Council on May 2 relating to the resignation of members within six months after election, was referred to a special committee consisting of the Treasurer, the Secretary of Council and the General Secretary to prepare an amendment to Article VII, Chapter VIII, covering the resolution.
On motion, L. E. Sayre was given the privilege of the floor and presented the following communication from Albert Schneider for the Committee on Drug Reform:

**RESOLUTIONS ON DRUG REFORM.**

Whereas, The national and the several states' pure drug laws have placed upon the pharmacists of the United States greater obligations regarding the supplying of drugs of standard quality, and

Whereas, The quality of the more important vegetable drugs now on the market is very inferior, and

Whereas, Adulteration of crude as well as powdered vegetable drugs is practiced to an alarming degree, and

Whereas, The vegetable drugs intended for percolation are not reduced to a suitable or uniform fineness, and

Whereas, The United States Pharmacopoeia is the legally recognized standard of the quality and purity of drugs, be it therefore

Resolved, That the following recommendations be submitted to the Council and General Assembly of the American Pharmaceutical Association for approval, and be it further

Resolved, That upon approval by the A. Ph. A. the recommendations be submitted to the Revision Committee of the United States Pharmacopoeia, with the request that immediate steps be taken by that body to carry out the suggestions embodied in the recommendations.

I. FININESS OF POWDERS AND MESH OF SIEVES.

The U. S. P. should give the required fineness of vegetable powders, specifying the diameter of the mesh of the sieve to be used. In giving the diameter of the sieve mesh the material used should not be included, that is, the measurements should give the diameter of the free opening only. Powdered vegetable drugs of which the fineness is not in accord with the pharmacopoeial requirements should be declared not up to standard.

II. AGE LIMIT OF VEGETABLE DRUGS.

Wherever possible the U. S. P. should state the age limit of vegetable drugs for crude as well as for those that are powdered. The U. S. P. should further give a table of corrections for variation in the activity of vegetable drugs, due to aging within the stated limit.

III. DIAGNOSTIC MICROSCOPICAL CHARACTERISTICS OF VEGETABLE DRUGS.

Every vegetable drug included in the U. S. P. should have a brief diagnostic description based upon its microscopical appearances, as per the following examples:

Under Rio ipecac should be given: "Starch granules simple to compound, simple granules not exceeding 13 in diameter: hili centric; polarizing phenomena not marked, acicular crystals and tracheids present. Ducts, base and sclerenchyma cells should be wholly absent."

Or under belladonna root: "Starch granules simple to compound, hili distinct more or less eccentric; simple granules from 6 to 17, polarizing phenomena marked, in direct ratio to size of granules. No acicular crystals, sclerenchyma cells or spiral ducts present."

IV. MAXIMUM PERCENTAGES OF IMPURITIES IN VEGETABLE DRUGS.

The U. S. P. should state the maximum amount of impurities permissible in vegetable drugs. For this purpose the vegetable drugs should be classed as follows:

Class A. Only a trace (1 per cent. or less) of impurities permissible, as ergot, kamala and lycopodium.

Class B. Impurities to not exceed 2 per cent., as most seeds, some fruits, ipecac, many barks, etc.
Class C. Impurities not to exceed 5 per cent., as some barks, some leaves, stems, flowers, flowering tops, etc.

Class D. Impurities not to exceed 10 per cent., as some roots, rhizomes, some barks, etc. Any vegetable drug with more than 10 per cent. of impurities (as sand, pebbles, dirt, foreign tissues, etc.) should be rejected as being below standard.

Respectfully submitted,

ALBERT SCHNEIDER.

Richmond, Va., 1910.

On motion of C. Caspari, Jr., seconded by Mr. Wilbert, the communication was referred to the Committee on U. S. Pharmacopoeia.

On motion of Mr. Whelpley, seconded by Mr. Wilbert, the Committee on Publication was directed to insert the pictures of P. C. Candidus and W. M. Searby in the 1911 Proceedings.

Adjourned to meet Wednesday, May 4, 1910, at 9 a.m.

J. W. ENGLAND, Secretary.

In answer to a question by Mr. H. P. Hynson as to the General Index, the General Secretary stated that the Association had on hand a stock of both bound and unbound copies—that it had quite a large number of unbound copies. Responding to further inquiry by Mr. Hynson, he stated that the Decennial Index would be printed in connection with the volume of Proceedings for that year, as had been the case in the past, and he did not think the suggestion made by Mr. Hynson that the Decennial Index be bound in with the unbound sheets of the Semi-Centennial Index was practicable, as it would involve an extra expense to members buying the Semi-Centennial Index, unless the Association desired to present a copy of the Decennial Index to members. Mr. Hynson said that his idea in making the suggestion was, that it would add very materially to the value of the Semi-Centennial Index, and it would save time and would cost very little, and he believed the Association could well afford to do that. He thought it would be well to refer the matter to the Council for consideration, and he so moved. Responding to a suggestion by Mr. C. E. Caspari, of St. Louis, that a great many of the members had already received copies of the General Index, and that provision should be made for the publication of the Decennial Index in the Proceedings also, Mr. Hynson replied that he had no desire to interfere with the publication of the Proceedings in any way. The Chair stated that without objection this matter would be referred to the Council for further consideration, and it was so ordered.

Secretary England read the minutes of the fourth session of the Council, held Wednesday, May 4, 1910:

Minutes of the Fourth Session of the Council.

The minutes of the previous meeting were read and approved.
The communication from Dr. V. E. Wiechmann, referred by the Council to the Committee on National Formulary, was referred back to the Council by the latter as having no power to grant the permission asked.

Moved by Mr. Caspari, seconded by Mr. Wilbert, that the Secretary of the Council write Dr. Wiechmann that the Council, at the present time, is not in a position to authorize the translation, and request fuller information as to the nature and extent of the translation to be made.

Moved by Mr. Wilbert, seconded by Mr. Lowe, that the Secretary of the Council write to the Chief of the Copyright Division, Library of Congress, asking for full information regarding international copyright laws, and the rights and privileges of American citizens and corporations under the same.

On motion of Mr. Whelpley, seconded by Mr. Lowe, it was decided to amend the by-laws so that the Board of Canvassers shall count as votes, in the annual election, only the votes of those members whose dues have been paid up for the current year.

Moved by Mr. Beringer, seconded by Mr. Lowe, that permission be granted Local Secretary Miller to post cards announcing an exhibit by the American Druggists Syndicate. This was not agreed to.

Applicants for membership Nos. 206 and 207 were elected.

J. W. England, Secretary.

The Chair directed attention to the fact that the work of the Council during the whole year had been of very great importance, and ought to be of great interest to the Association. He said the Association was to be congratulated upon having another Branch at Nashville, and that the indications were that it would be a strong one. This Branch, he said, had been established largely through the efforts of Mr. Burge, of that city, who had come before the Council with the names of 21 new members from Nashville, and has since added two more. He said he was sure the Association wished the new Branch the greatest success.

On motion of Mr. Hynson, seconded by Mr. Eliel, of Indiana, the minutes of the Council were then approved as read.

The Chair here called for action upon the proposed amendments to the By-Laws submitted at yesterday's session. He said he gave this matter precedence at this time because certain other work to be done by one of the Branches of the Association could not be approved until this amendment of the By-Laws was adopted.

The Secretary read the first proposed amendment, to Article I of Chapter X of the By-Laws, proposed by Mr. Beal at the first session, to change the word "ten" in the first line to "eleven," and to insert after the sixth word in line 3 (members) the words "a Committee on Pharmaceutical Syllabus of seven members;" the effect of the amendment being to make an additional Standing Committee, as indicated.

Mr. W. L. Scoville, of Detroit, wanted to know why a Syllabus Committee was considered necessary, and what its work was to be. President Rusby thereupon made the following explanation:

The Pharmaceutical Syllabus consists of a syllabus of instructions which it is considered as appropriate that schools of pharmacy should adopt;
and it is also hoped that not only will this become the basis for pharmaceutical instruction, but that it shall become the basis of examination by the Boards of Pharmacy. It is, in short, an attempt to promote harmonious action between those giving instruction in the colleges and those who are to determine the fitness of candidates for license because they have had that instruction. There is nothing binding about it, but something to indicate the ideas of this Association as to what pharmaceutical instruction and examination should be. The Syllabus has already been published. We have done this, not under the sanction of a standing committee, but through our Section on Education and Legislation, in combination with the Conference of Pharmaceutical Faculties and the Association of Boards of Pharmacy. We have been working on this for two years past. That Syllabus has now been published, as I say; but it is a tentative Syllabus—a beginning, a foundation. It is probable there are weaknesses in it which we will want to change, and it is indeed expected that all the Boards of Pharmacy and all the Colleges of Pharmacy will take that Syllabus and send in their ideas as to changes that should be made in it, so that at the end of five years we may republish that Syllabus in revised form, so as to thoroughly represent the ideas of the Boards of Pharmacy and Colleges of Pharmacy. We could do this without action by this Association, but there is some small expense attached to it, some $10 or $15 a year for each of the three branches of the Association; and, as you know, it is impossible for a Section of the Association to appropriate money, except by consent of the Association in general session.

Further answering an inquiry by Mr. Scoville, the President stated that this proposed Committee on Pharmaceutical Syllabus would take the place of the Committee which had gotten out the present Syllabus, and this matter would hereafter be the action of the Association—would express the views of the Association, instead of one of its Sections.

Thereupon the Chair put the vote upon the motion to amend Article I, Chapter X of the By-Laws in the way indicated, and it was carried.

The Secretary read the next proposed amendment of the By-Laws as offered by Mr. Beal, to add to Chapter X, Article XII, as follows:

Article XII—The Committee on Pharmaceutical Syllabus shall be appointed by the President of the Association as follows: One member shall be appointed for seven years and one for six, five, four, three, two and one years respectively; each vacancy occurring from expiration of term shall be filled for a term of seven years: other vacancies shall be filled at the annual meetings of the Association for the unexpired term. This Committee shall report to the Association through the Section on Pharmaceutical Education and Legislation, shall be members of the National Committee on Pharmaceutical Syllabus and shall recommend to the Association its proportionate share of the current expenses.

On motion of Mr. F. W. Meissner, of La Porte, Ind., duly seconded, this proposed amendment to the By-Laws was also adopted.
The Secretary gave notice of a proposed amendment of Article III, Chapter III, of the By-Laws, made necessary by some amendments to the By-Laws last year. His motion was to eliminate the last sentence in Article III, referring to the General Secretary—"He shall notify every member at least two weeks in advance of the time and place of each annual meeting;" and to insert in lieu thereof the sentence "He shall publish in the Bulletin a notice of the time and place of next meeting at least four weeks prior to the date of the next meeting." The Chair stated that this would be acted on at the next session.

Mr. Hynson, of Baltimore, said he also wanted to offer a proposition to amend the By-Laws. He said that the Commercial Section of this Association was either a benefit or a detriment to the Association; that it had been presided over since the days of the "immortal Jacobs," of Atlanta, by Messrs. Rapelye, Hopp, Anderson, Mason and others, including himself, and all of these had worked zealously to make something out of that Section, but without much result to show for it. His proposition was, therefore, to change the name of the Section from that on Commercial Interests, to the Section on Ethics and Practice, and his motion would be open for discussion at the next session.

The Chair called on the Secretary to read the proposed amendment, which he did as follows:

**PROPOSITION TO AMEND BY-LAWS.**

Chapter IX, Article II, line 3. Strike out the words "Commercial Interests" and insert the words "Ethics and Practice" in their places.

Article V, line 1. Strike out words "Commercial Interests" and insert the words "Ethics and Practice" in their places.

Chapter X, Article I, line 4. Strike out the words "Commercial Interests" and insert the words "Ethics and Practice" in their places.

Article II, line 1. Strike out the words "Commercial Interests" and insert "Ethics and Practice" in their places.

H. P. HYNSON.

The Chair asked if there were any other proposed amendments to the By-laws, but none were offered.

The Secretary said he would like here to call attention to two short communications which he thought the Association would be glad to hear. He said the General Secretary had been instructed at yesterday morning's session to send telegrams of fraternal greeting to the former Treasurer of this Association, Mr. Samuel A. D. Sheppard, of Boston, now at Pinehurst, North Carolina, on account of his health. He had received reply by wire from him, which he would like to read:

**PINEHURST, N. C., May 4, 1910.**

*To American Pharmaceutical Association:*

Warmest thanks for kind remembrance; only hard necessity keeps us from the meeting. May you do your usual good work, and thus keep true pharmacy in the front rank.

S. A. D. SHEPPARD.
The Secretary said the next communication was from an honored ex-President, Mr. William Saunders, of Ottawa, Canada, and he would read his letter, omitting the personal parts of it:

**DOMINION OF CANADA.**

*Department of Agriculture.*

*Ottawa, Ont., March 7th, 1910.*

THOS. F. MAIN ESQ., 164 Chambers St. New York, N. Y.

_Dear Friend:_ I thank you for your very kind letter of March 3rd which is just received. The work I have been doing for twenty-five years past has been most interesting and one which has given me a great deal of enjoyment in carrying out. It is very gratifying to have so many friendly compliments passed on one's work and I value such kind expressions very fully when they come from my old pharmaceutical friends.

I should like very much to be present at the meeting in Richmond, Va., in May, but it would be quite impracticable, as I am starting a new Experimental Farm at Charlottetown in Prince Edward Island, and will necessarily have to be there about that time, and from that point I shall go off to do similar work in Saskatchewan. I hope you will be good enough to remember me kindly to any of my friends who may ask for me, and express my regrets that I shall be unable to be present in person.

With kind regards, yours very truly,

WM. SAUNDERS.

Mr. Thomas F. Main, of New York, moved that the Secretary send a telegram of fraternal greeting to Mr. Saunders, and also the hearty congratulations of the Association on the magnificent work Mr. Saunders was doing in the establishment and extension of what is known as "experimental farming" in the Dominion of Canada.

Mr. John F. Hancock, of Baltimore, also paid tribute to Mr. Saunders as a man of ability, and said he had done a great service for Canada—as one of the recent journals had put it, "he has been of more use than all the politicians of Canada to that Province." He said he was a man worthy of the highest regard by the members of this Association, and he took pleasure in seconding the motion of Mr. Main.

Mr. F. E. Stewart, of Philadelphia, moved to amend by sending a written communication instead of a telegram, so that the Association might express itself a little more fully. Mr. F. M. Apple, of Philadelphia, suggested a "night letter" by wire.

Mr. Main paid further tribute to the valuable work Mr. Saunders was doing, and said that if any of the various members visited Ottawa at any time, he would advise them by all means to go to the "Experimental Farm" there, whether Mr. Saunders was present or not, and let it be known they were members of the American Pharmaceutical Association, and he said they would be heartily received and conducted over the grounds. Mr. Saunders, he said, had established these farms all over the Dominion of Canada, as he understood, and he would earnestly advise any of the members who happened to be in the vicinity of one of these farms not to miss the opportunity to visit it.

The Chair then put the motion to send the greetings and congratulations of the Association to Mr. Saunders by letter, and it was carried.
The next report called for was that of the Treasurer of the Association, Mr. H. M. Whelpley, of St. Louis.

Mr. Whelpley said that perhaps as the members had observed by the reading of the minutes of the Council, the annual report of the Treasurer would not be complete until the end of this fiscal year, June 30, 1910. He said he had prepared a summary of the financial condition of the treasury, but even this was likely to be misleading, on account of the relation between the receipts and expenses not corresponding with each other when taken for the first eight months of the year. There were, however, other things about the Treasurer's work which could be stated with more accuracy, especially as to the invested funds of the Association, which increased little by little, month by month, and concerning which a statement might be made at any time during the year.

Mr. Whelpley stated that one matter which was of particular importance was that of the collection of dues. Two years ago there were members carried on the books who were in arrears of dues as much as five years, and quite a number owed for four years, while there were many delinquents for three years. At the present time, however, the Association had no members who owed for more than two years. At the annual meeting in Los Angeles last year he read a list of those who were to be dropped for non-payment of dues, and the reading of that list had saved quite a number of these members to the Association, because of the interest taken by certain persons present to see that the delinquent members did not permit their names to be dropped from the rolls. The list of those delinquent for two years was now 146, and Mr. Whelpley said he was particularly anxious to find members present who would co-operate with him in an effort to save as many as possible of these to the Association, and avoid the necessity of the publication of their names in the volume of Proceedings as having been dropped for non-payment of dues.

After the reading of this list, and the eliciting of various responses and inquiries by members, Treasurer Whelpley said that he had, in his efforts to collect these dues, mailed fourteen different communications to those whose names had been given—eight of them bills and six of them letters.

Mr. Hynson noted the fact that a number of members of the various Boards of Pharmacy on this list were delinquents, and suggested that they, at least, should see to it that their names should not appear in the printed list of those dropped.

Treasurer Whelpley next took up in abstract a statement of the invested funds of the Association, and pointed out how they had grown in the past year. For instance, the Life Membership Fund, the largest fund of the Association, had increased from $16,629.90 on July 1, 1909, to $17,141.68 at this date. The Endowment Fund had increased from $3,634.35 to $4,934.70, the largest item of which increase was the munificent gift of Mr. Charles E. Dohme, of Baltimore, of $1,000, just before the Los
Angeles meeting. Mr. Whelpley also showed $2,822.90 in a new fund known as the "Ebert Legacy," the Ebert Fund proper standing at $938.36, and that the Centennial Fund had increased from $2,329.67 to $2,386.25; the total amount of the invested funds to date, as shown, being $28,223.89. These figures are comprised in and are a part of the detailed report of the Treasurer as of July 1, 1910, appearing a little further on.

Mr. Murray Galt Motter, of Washington City, arose to a point of personal privilege, and asked that his name be not used in connection with the fund held in trust for the National College of Pharmacy, referred to in the Treasurer's report, which fund was given with the distinct understanding, he said, that his name was not to be attached to it. He said the reason he had not made this motion at the Los Angeles meeting was because he was not present and could not do so. The Treasurer responded that the name had been used as found upon the books of the former Treasurer that had come to him, and suggested that it would take formal action of the Council to justify a change in the record. He said he would be glad to accede to the request, if properly authorized. Thereupon Mr. W. L. Cliffe, of Philadelphia, moved that Mr. Motter's request be referred to the Council for action, and this motion was seconded by Mr. Godbold, of New Orleans, and carried.

Mr. C. S. N. Hallberg, of Chicago, expressed the opinion that only individual names should be appended to the contributions to such funds, and called attention to the fact that a name was attached to a contribution of $10 to one of these funds, which, in his opinion, was in conflict with the Constitution of the Association. He moved, therefore, that the Treasurer be instructed to either return the money or credit it to an individual, and not to an anonymous chemical corporation. The Treasurer explained that this was a fund that the Association held in trust, and that the money came to the Treasurer of the Association from the treasurer of the Committee on the Procter Monument Fund, and that perhaps all he could do was to make the entry of the remittance as it came to him, and he suggested that the motion be modified in such a way as that it might be directed to the Committee, rather than to the treasurer. The Chair held, however, that this motion was out of order at this time, and would properly come up when the report of the Committee on the Procter Monument Fund was brought up for consideration.

Thereupon, upon the motion of Mr. L. E. Sayre, of Kansas, seconded by Mr. Philip Asher, of New Orleans, the report of the Treasurer as made was received.

The Treasurer's completed report, as of July 1, 1910, here follows:
MINUTES OF THE THIRD SESSION.

REPORT OF THE TREASURER OF THE AMERICAN PHARMACEUTICAL ASSOCIATION, JULY 1, 1909, TO JULY 1, 1910.

PROSPECTIVE ASSETS.

Not counting the amount due from members who will probably be suspended this year for the non-payment of dues nor from the members whose residences are unknown, there is outstanding on the books of the Association, July 1, 1910:

Annual dues for 1909 (290 members) ........................................ $1,450 00
Annual dues for 1910 (1,309 members) ...................................... 6,545 00

$7,995 00

This does not make an allowance for about 125 of the members who now owe $10.00 each, and are likely to be suspended for the non-payment of dues in 1911.

Respectfully submitted,  
HENRY M. WHELPLEY, Treasurer.

July 1, 1910.
ADDENDUM TO THE TREASURER'S REPORT, 1909-10.

The meetings of August 10, 1909, and May 3, 1910, both came within the fiscal year, just closed, and this report will appear in the Proceedings without being submitted at an annual meeting in the usual manner.

The increase in membership has been about the same as last year when the comparative lengths of the administration years are considered.

*The Special Funds* on July 1, 1910, are as follows:

This is my second annual report as Treasurer, and I appreciate the co-operation of my associate officers in my effort to keep the Association in as good a financial condition as possible. The number of members to be suspended for the non-payment of dues is larger than I anticipated, in spite of systematic and persistent efforts to reduce the number to a minimum. Among those to be suspended I find the names of many who recently joined, and evidently do not appreciate membership in the Association. The number of older members to be dropped is gratifyingly small. This indicates that some are willing to join and pay one or two years' dues and then be suspended for the non-payment of dues. I must particularly thank the officers, the members of the Council and
the members of the General Committee on Membership for their co-operation in preventing delinquent members from remaining on the suspension list. Letters from personal acquaintances and calls by local associates have saved quite a number who would otherwise have been suspended this year.

Very truly,
HENRY M. WHELPLEY, Treasurer.

July 1, 1910.

The report of the General Secretary was called for as the next order of business.

The Secretary stated that, as in the case of the Treasurer, his statement of the financial accounts in his care was only a partial one, and that a complete report for the year would be ready on July 1st. He then proceeded to make a summary of his accounts for the past nine months. His report complete for the fiscal year ending June 30, 1910, here follows:

REPORT OF THE FINANCIAL ACCOUNTS IN THE CARE OF THE GENERAL SECRETARY.

A. RECEIPTS AND EXPENDITURES ON ACCOUNT OF THE NATIONAL FORMULARY FROM JULY 1, 1909, TO JULY 1, 1910.

I. Receipts.
From Sales and Payment of Bills due July 1, 1909 .................. $4,154 91

II. Expenditures.
Paper and Press Work, 3,100 copies at 8.55 cts. .................. $265 08
Binding 3,300 copies in cloth at 11 1/2 cts. .................. 379 50
Binding 450 copies in sheep at 28 1/6 cts. .................. 128 25
Rebinding 14 copies .................................. 2 00
Expressage, $108.07; Postage, $25.16 .................. 133 23
510 Mailing Cases .................. 7 65
38 Packing Boxes at 25 cts. .................. 9 50
Typewriting done at office of Chairman Diehl .................. 106 80
Typewriting for the Committee .................. 3 00
Stationery for the Committee .................. 8 48
Mimeograph Supplies, $18.95; Paper, $6.95 .................. 25 90

Cost of 40 Gold Bars, received April 30, 1910 28 00
Registration Fees 18

Total $1,556 27

Baltimore, July 1, 1910.

Chas. Caspari, Jr., General Secretary.
The Chair stated that, without objection, the report of the Secretary would be accepted and placed on file, and it was so ordered.

REPORT OF THE AUDITING COMMITTEE.

Dr. James H. Beal, Chairman Council A. Ph. A.:

Dear Sir: We have examined the books of Henry M. Whelpley and Charles Caspari, Jr., respectively Treasurer and General Secretary of the American Pharmaceutical Association, for the fiscal year 1909-10 and compared the records with the vouchers and found them correct. We have found a proper accounting for all the funds of the Association. The cash balance on June 30, 1910, corresponds with the book of the International Bank of St. Louis and the registered bonds in the hands of the Treasurer.

F. G. Uhlich, Chairman,
Otto F. Claus,
L. A. Seitz, Auditing Committee.

St. Louis, Mo., July 30, 1910.

REPORT ON THE INVESTED FUNDS OF THE ASSOCIATION.

St. Louis, July 30, 1910.

To the Officers and Members of the American Pharmaceutical Association:

We, the undersigned, have in accordance with Rule 6 of General Rules of Finance, examined the securities contained in the Association Box (4227) at the Title Guaranty Trust Co., St. Louis, and found the following:

A. Ph. A. General Fund Bonds.

5 St. Louis City Reg. 4 per cent. Bonds, Nos. 705, 706, 707, 708, 709 $5,000 00
1 St. Louis City Reg. 4 per cent. Bond, No. 717 5,000 00

Total $10,000 00

A. Ph. A. Centennial Fund Bond.

1 Mass. State Reg. 3 per cent., No. 1705 $1,000 00

A. Ph. A. Life Membership Fund Bonds.

1 Mass. State Reg. 3 per cent., No. 1701 $10,000 00
3 Mass. State Reg. 3 per cent., Nos. 1702, 1703, 1704 3,000 00

Total $13,000 00

A. Ph. A. Procter Monument Fund.

Certificate of Deposit No. 57,115, July 1, 1910, International Bank of St. Louis $3,894 92

H. M. Whelpley, Treasurer,
F. G. Uhlich, Chairman Auditing Committee.

Subscribed and sworn to before me this 30th day of July, 1910. Witness my hand and notarial seal.

[Seal]

My term expires June 13, 1913.

An opportunity was here given Mr. Remington, Chairman of the Special Committee, to consider the desirability of the publication of the National Formulary by the U. S. Pharmacopoeial Convention, to make report, and he presented the following:
REPORT OF COMMITTEE TO CONSIDER THE DESIRABILITY OF CHANGE IN PUBLICATION OF THE NATIONAL FORMULARY.

Your Committee to whom was intrusted the duty of reporting upon "the desirability and practicability of turning over the publication of the National Formulary to the United States Pharmacopœial Convention," respectfully report that after due consideration this recommendation of our honored President is not approved.

The National Formulary is an inheritance of the American Pharmaceutical Association, upon which much labor has been spent by this body, and the National Food and Drugs Act designated the National Formulary as one of its standards, and this without any solicitation on the part of this Association. It is believed by your Committee that every effort should be made to improve the National Formulary by eliminating its shortcomings and introducing standards, but they believe that it should remain the property of this Association and given the heartiest support of all of its members. There should be co-ordination between the U. S. Pharmacopœia and National Formulary Committees to prevent duplication or confusion in the standards.

Joseph P. Remington,
William C. Anderson,
L. F. Kebler,
C. Lewis Diehl,
George M. Beringer.

Mr. Hynson, seconded by Mr. Meissner, moved to accept the report of the committee as read, and the motion prevailed.

The Chair called for the report of the Committee on Reorganization as the next business in order, and Mr. Hallberg, chairman of that committee, presented the following report:

REPORT OF THE COMMITTEE ON REORGANIZATION.

To the American Pharmaceutical Association:

The committee has carefully considered the recommendations made by President Oldberg in his address at the last annual meeting as to changes in the By-Laws, etc. These were referred to the Committee on Reorganization by the Council, to which this committee has reported.

There are a few additional suggestions that this committee would like to make as recommendations, as follows:

1. That when a member is in arrears in dues more than one year that he be notified, and that unless such dues are paid within thirty days his name be stricken from the rolls.

The reason for this suggestion is the conviction that according to our present plan members fall behind in their dues without realizing the seriousness of their position, and when they owe an amount of from $10.00 to $15.00 it is very difficult to get them to pay up, and the result is that their names are dropped any way. It is our belief that not as many members will be lost if this rule is enforced, as it is in all other organizations. One hundred and twenty names have been dropped for non-payment of dues since the last annual meeting.

2. That the Treasurer issue a little pocket-card as a membership receipt for the current year, and that every member on registering at the meeting must show this card or receive a duplicate from the Treasurer in order to qualify him to register as a member.

3. That to only such registered members the badge, program, invitations and such other matter as is usually given to members be issued.

4. That provision be made for the families of the members and other visitors by providing them with a visitor's badge and such other matter as may be decided by the Local
Committee of Arrangements; that a blank be devised to be filled out for such members' families and visitors, signed by a member recommending him. Also the following:

5. That the "Bulletin" of the A. Ph. A. of the month preceding the annual meeting be a complete program of such meeting or a separate program be published; that it contain the programs of all the Sections, abstracts of papers and all similar matter desirable as information to the members concerning the meeting.

6. That the Chairman of each Section be required to transmit to the editor of the "Bulletin" such program or abstracts not later than thirty days prior to the meeting, or within time sufficient for its publication.

7. That papers may be printed in advance, but that the original paper be given to the Secretary of the Section to be certified by him and the retiring Chairman of the Section.

8. That such papers are eligible as publications of the A. Ph. A. only when thus certified.

9. That such papers be turned over to the General Secretary and become the property of the Association, but papers printed in advance may, when certified, become public property.

The question of concurrent sessions of the different Sections seems to be solving itself through the only method satisfactory, namely, experience. Since this was regarded as the most important change desired, there is no further change proposed except the wish that in the very near future the Association may be able to concentrate its meetings within four days.

Respectfully submitted,

E. G. Eberle, Dallas, Tex.,
M. I. Wilbert, Washington, D. C.,
C. S. N. Hallberg, Chairman, Chicago, Ills.

Chicago, April 27, 1910.

Mr. Mayo, of New York, duly seconded, moved to accept and adopt the report just made.

Mr. George M. Beringer, of New Jersey, asked if the passing of that motion carried with it the ruling of the Association, and upon being answered by the Chair in the affirmative, moved that ninety days be substituted for the thirty days' notice to delinquent members provided in the report.

Mr. Hallberg objected to this motion, and stated that the reason the Committee had put it at thirty days was because the Committee believed that would give the delinquent ample time to collect the money to pay his dues, and he would not be likely to forget it, whereas he would be likely to forget it if he were given three months' notice. He said the By-Laws specifically provided that the Treasurer was to notify the delinquent that he would be required to pay within thirty days, and, failing to do so, his name would be reported to the Council, and the Council might hold him up until such time as it saw fit.

At this point Mr. Hynson asked Chairman Hallberg if he would not like to have this matter referred to the Council, and Mr. Hallberg responded that there would be no objection to that. The Chair, however, suggested that there might be a practical objection to this, if it involved a change in the By-Laws, as, if the Association waited on the Council to act, there might not be time then to make the necessary changes in the By Laws.
The motion to refer to the Council was seconded by Messrs. Apple and Sayre.

Mr. Beringer renewed his objection to the thirty days' clause, and argued for three months as entirely reasonable, particularly as that was a great curtailment of the time for dropping delinquents as compared with the present status. He reminded the members that the question of membership was a vital one to the Association, and the proposition of maintaining the membership at anything like a respectable proportion of the many thousands of pharmacists of America was a serious one. He felt that so short a time might perhaps do an injustice to members who were ill or away from home at the time, and he considered it a matter of simple justice to all the members that the time of notice should be at least three months before dropping a member from the rolls.

Mr. Harry B. Mason, of Detroit, suggested that a word from the Treasurer on this subject might be of value.

Treasurer Whelpley said that he did not quite understand this feature of the proposed amendments. He wanted to know from what date the thirty days' notice was to apply. Mr. Hallberg said it was to run from the end of the fiscal year for which the dues accrued. Mr. Whelpley said he understood this to mean that those who might now owe for the fiscal year beginning the first of July last would be dropped after the first of August next for non-payment of dues. Mr. Hallberg answered in the affirmative, stating that if such delinquent members did not pay within thirty days from the first day of July next their names would be presented to the Council.

The Chair agreed with Mr. Beringer that a change to three months would be desirable, as a large number of members might be away on their vacations at that particular time and would not get the notice until their return.

Continuing, Treasurer Whelpley stated that the plan of referring to the Council did not appeal to him as a very practical one. He said he thought the matter should be left as largely as possible in the hands of the Treasurer, as he came in personal contact with the members through correspondence, and the Council was not in a position to judge, except on the advice of the Treasurer. At one time the Association had made it exceedingly difficult for a member to get out of it, and almost as difficult for him to get back again after having once gotten out. There was a time when delinquent members were carried on the books for six years, and if a member fell behind one year, and desired to be dropped, he was carried on the books for three years—because the By-Laws said at the end of three years a member should be dropped or suspended for non-payment of dues. But now the By-Laws and rules and customs have been changed, and if a member desires to be dropped for non-payment of dues, and he owes for only one year, he can be dropped, and don't have to be carried
for three years. There was also a time when, in order to get back into the Association, it was necessary for delinquent members to pay up all the dues owing at the time they were dropped, but now the delinquent is taken back without paying any of such dues, and comes in as a new member. Mr. Whelpley said that the Association was gradually working down to the point where the energies of the Treasurer would be devoted to the first twelve months of delinquency. He said that, personally, he would like to see what could be done along these lines, before a radical change was made in the present system.

Mr. J. L. Lemberger, of Pennsylvania, was in favor of moving very slowly in the matter of dropping members. He said that in the Pennsylvania Association they had found it was much better to move along conservative lines than to act rashly. The Chair suggested that they were "slower in Pennsylvania" than in this Association. Mr. Lemberger agreed that "Philadelphia was slower," but reiterated his doubts of the wisdom of adopting such a radical change as that set forth in the report of the Committee. He asked if this question had been considered by the Council, and the Chair responded that the substance of it had been—that the general idea of dropping after one year had been considered and approved. Mr. Lemberger said that some of the changes as indicated by the report seemed to him severe, and that an experience of thirty years along these lines led him to feel that the Association ought not to act so hurriedly, so rashly, in this matter, and he hoped that this part of the report would be modified.

Mr. Thomas F. Main, of New York, said that he thought the differences of opinion on this proposition had been drawn out in a way to inform the Council that there was a difference of opinion as to the time that should elapse after notification before dropping a delinquent member, and that he was in favor of so referring the report.

The motion to refer to the Council was then put to a vote and carried. The next committee report submitted was that of the Committee on Parcels Post, which, in the absence of the Chairman, the Secretary presented as follows:

REPORT OF COMMITTEE ON PARCELS POST.

To the American Pharmaceutical Association Convention, assembled:

Your Committee on Parcels Post has very little to report at this time, as up to three weeks ago there seemed to be no prospects of any hearing at this session on any Parcels Post Bill, either rural or general. The committee kept posted during this time, and it did seem as if there would be nothing to do. But the Committee on Post Offices and Post Roads decided to have a hearing on the Parcels Post Bills so that all persons interested, for or against it, might be heard. The hearing began on April 25 and continued for five days. Your committee appeared and strongly opposed the adoption of a Parcels Post. Representatives of nearly all the retail interests of this country also appeared before the committee in opposition to the adoption of any form of this bill. The combined retail interests of this country put up very good reasons why the government
should not adopt a Parcels Post. It looked to the chairman of your committee as if the real promoters of the bill were interested in mail order business. At this time it is unknown whether or not the committee will make a report at this session, as there is probably not enough time to go over and formulate any kind of a report, as it is quite late in the session.

Respectfully submitted,

W. S. Richardson, Chairman.

On motion of Mr. Sayre, seconded by Mr. Eliel, the report as read was accepted and adopted.

F. L. Hilton, Chairman, read as follows the report of the Committee on National and State Legislation:

REPORT OF THE COMMITTEE ON NATIONAL AND STATE LEGISLATION.

To the Officers and Members of the American Pharmaceutical Association:

In offering this annual report on behalf of the Committee, I feel that as Chairman of the Committee I should offer apologies to the other members of the Committee, at this time, for the reason that I have been unable to present to them for their consideration, this report previous to the meeting.

The time elapsing since last meeting being so short, Congress still in session, and the fact that the Chairman, by sickness was compelled to lose a month, it has been impossible for me to prepare a report until practically the last minute. The report now may fail to bring out some important matters enacted by Congress the past few days.

Before presenting a resume of what has been accomplished the past year with respect to legislation of a national character only, I desire to call the attention of the President and members of the Association to the fact that the report of this Committee at the Los Angeles meeting contained recommendations which were adopted, namely, that this Committee be made a committee on National Legislation and transfer all matters pertaining to State legislation to the Section on Education and Legislation and concentrate its efforts on legislation proposed to Congress and thereby eliminate the multiplication of committees dealing with legislation. (See Proceedings 57, p. 529).

On looking over the proceedings this committee as named remains the same, the Committee on National and State Legislation, and numerous other committees have been appointed to take charge of special legislation, thus again a multiplication of committees to handle this subject, therefore the past year in each and every case where bills have been introduced or hearings held on matters pertaining to legislation for which a special committee had been appointed, the Chairman of this Committee did not take any part, consequently this report does not contain any reference whatever to legislation for which a special committee had been appointed.

The recommendations adopted at the Los Angeles meeting with respect to having a bill passed by Congress empowering the Interstate Commerce Commission to regulate the express charges of the country has not been taken up by the Committee for the reason, the chairman was not aware of such recommendations until he received his copy of the "Proceedings" about ten days ago.

During the two sessions of the sixty-first Congress, the second of which has not as yet adjourned, over 33,000 bills have been introduced, many of which affected the interests of the pharmacist, only one of which has as yet become a law, the bill known as the Insecticides Bill.

Of all the bills introduced and now pending that is most obnoxious to both the practice of medicine and pharmacy, and the bill that requires close observation, is the one introduced by Congressman Coudrey, providing for the government editing and publishing the U. S. Pharmacopoeia. This bill is poorly drawn, and in its present form is ab-
solutely ambiguous and absurd. With the changed conditions in Congress that have been recently brought about, it is an exceedingly difficult matter to predict what may or may not occur in the future, what has heretofore seemed likely to receive no consideration is now being pushed forward with the evident purpose of gaining as much advantage as possible, and is clearly demonstrated by the fact that the Committee on Post Offices and Post Roads decided to grant hearings on all Parcels Post measures April 25th, after previously stating no hearings would be held this session; not knowing what forces are pushing the Coudry bill, we do therefore then recommend that this bill be kept under close observation, and that the American Pharmaceutical Association concentrate every possible effort to defeat it.

Following the recommendations of last year we have purposely omitted all comments pertaining to state legislation, believing that the Section on Education and Legislation will discuss the subject fully, as has been the custom.

The most important bills affecting the pharmacist and now pending are as follows: bills establishing a department of Public Health, bills amending the statutes relative to trademarks and patents, bills to prohibit the transportation and the sale of spirituous, vinous and malt liquors, in states having prohibition laws, a bill to regulate the manufacture of smoking opium, a bill imposing a tax upon and regulating the production, manufacture and distribution of certain habit forming drugs in interstate commerce, a bill to regulate the transportation of habit-forming drugs in interstate commerce, a bill to regulate the practice of pharmacy and sale of poisons in the consular districts of the United States in China, numerous bills proposing amendments to the Food and Drugs Act, and a bill to prevent the manufacture, sale and transportation of adulterated or misbranded paint.

The bills proposing to establish a Department of Public Health have not been fully considered by the Committee having the matter in charge, while these bills affect a few of the pharmacists in the government service only, they are for the public good and if the pharmacists are properly cared for they should receive our endorsement. Some provision should be made to amend the bill so as to provide for a bureau of pharmacy. This Committee has taken no action owing to lack of knowledge of the position of the Association with reference to the proposition.

Of the many bills relating to amendments to the trade-mark and patent laws, several of minor importance have been reported, placed on the calendar, but none have been acted upon by either house of Congress. Our aim with reference to amending the patent laws should be along the same lines as recommended last year, that is, not to grant any more rights and privileges to a citizen of a foreign country than what the respective foreign country grants to a citizen of the United States: any bill with this purpose in view should have our support.

The bills relative to aiding States in preventing the sale of spirituous, vinous or malt liquors where said State laws prohibit such sales should have our support, provided provision is made whereby druggists can procure their alcohol for use in manufacturing medicinal pharmaceutical preparations. The time has arrived when it is necessary for pharmacists to divorce from their business the sale of all alcoholic beverages. We should be pharmacists and not rumsellers, and relinquish to licensed dealers the sale of all alcoholic beverages even although the demand should be by prescription.

The bill to regulate the manufacture of smoking opium is of so little importance to the drug trade, the justice of same so apparent and the necessity for stringent laws so urgent for governing it, we should unhesitatingly support any measure that has for its purpose the abolishment or the better control of such practices.

The bill imposing a tax upon and regulating the production, manufacture and distribution of habit forming drugs, known as the Cullom bill, should have our support. This bill requires all dealers to be licensed and the internal revenue laws are to be amended
so that this branch of the government service will have complete charge of the enforce-
ment of the provisions of the bill, if it should become a law. It prescribes to whom
licensed dealers may sell in interstate commerce. It does not interfere in any way with
the State controlling such matters within its borders, but such a measure will prohibit
the promiscuous sale of habit-forming drugs to every one except licensed dealers in in-
terstate commerce. The recent exposé of the deplorable conditions existing in one of
our large cities, clearly shows that the same conditions exist in nearly, if not every one
of our large cities and the honest pharmacist should use every power at his command in
assisting the authorities to put a stop to such practices for the sake of humanity and
thereby help to save the lives of thousands of persons. The bill to regulate the sale of
habit-forming drugs in interstate commerce would seem to control the situation, yet in
the judgment of the Chairman of this Committee, it will not secure the results as well as
the previous bill that has been discussed compelling the licensing of all dealers; there-
fore I would recommend that this Association lend its support and direct its efforts to-
ward securing the passage of the bill known as the Cullom bill.

The bill to regulate the practice of pharmacy in consular districts of the United States
in China does not need any consideration other than to see that the provisions thereof
are in conformity with the same provisions usually followed in this country

Of the bills proposing amendments to the Food and Drugs Act, the one providing for
the editing and publishing of the U. S. Pharmacopoeia by the U. S. government has been
noticed, and requires no further comment.

The amendment compelling all drugs recognized by the U. S. P. and N. F. to be of
the standard provided for by the U. S. P. and N. F., and if where no standard is pro-
vided, giving authority to the Secretary of Agriculture to establish standards, should be
carefully considered before any action is taken.

The pure paint bill while not affecting the retail drug trade to any extent should be
supported; there is no reason whatever why we should not have pure paints as well as
pure drugs.

Before bringing this report to a close I desire to call the attention of the Association
to what has been accomplished the past year by the careful and judicious enforcement
of the Food and Drugs Act by the department having this duty in charge. The depart-
ment has secured since January 1, 1910, decisions from the courts in 135 cases, 29 of
which were drug cases, and has lost but one case. In conjunction with the Treasury
Department they have prevented the introduction of many lots of spurious or adulterated
drugs from entry.

The work performed with reference to lemon oil is most exhaustive and will prove of
much benefit to the people of the United States. Many other investigations have been
made that will prove valuable at this time to both medicine and pharmacy. Food In-
spection Decision 112, amending regulation 28, the labeling of derivatives has caused
some uneasiness in certain quarters; under this regulation as amended, it is now neces-
sary not only to specify the substance on the label, but to clearly state from what sub-
stance it is derived, as for example, codeine, derivative of opium. While this decision
was promulgated early in January, it did not become effective until April 1st, thereby
giving sufficient time to make necessary changes in labels.

In conclusion, the Chairman desires to extend his most sincere thanks to the members
of the committee, and on behalf of the committee, to thank the officers and members of
the Association for the confidence and trust placed in them to look after the Associa-
tion's interests and to carry out its wishes.

In completing the year's work the Chairman personally desires to thank the officers
and members for the confidence placed in him. I have served as a member of this Com-
mmittee for three years, and as Chairman the past two years; I fully believe in rotation
in office, and on the advice of my physician I have informed the newly-elected President
of my inability to again serve as Chairman of the Committee. While I have found this work exceedingly pleasant, it is now necessary for me to relinquish this charge; I will always have the interests of this Association at heart, and I assure you whenever an occasion should arise whereby I can be of assistance, I will do all within my power to advance its interests.

Circumstances over which I have no control compel me to take this step and to decline to serve any longer on the Committee.

Respectfully submitted,

S. L. Hilton, Chairman.

The Chair said he wished to express his thanks to the Chairman of this Committee and his colleagues for the valuable work they had done. He said there were two recommendations in the report.

Mr. Hallberg said there were several recommendations in the report that he thought should be very carefully considered: That some things had transpired since the report of the Committee was drawn which were not included in it. He believed that the Association was scarcelyly in a position this morning to discuss the recommendations of the report, and expressed the opinion that if it were referred to the Section on Education and Legislation it could be discussed much more intelligently. He moved to so refer it, and the motion was seconded by Mr. Sayre.

The Chair asked Mr. Hallberg if it was his idea that such reference meant that the Section would have power to act upon the recommendations for the Association and approve them, or whether they would come back to the Association for final action. Mr. Hallberg replied that whatever action might be taken in the Section would be reported back to the Association in final session.

The Chair said he would put the motion to refer to the Section on Education and Legislation for consideration, with the understanding that that Section should report back to the Association in general session its recommendations. He said he would suggest that it might be well when this was done for the Chairman of the Committee to submit to the Section on Education and Legislation copies of the two bills to which reference was made in the report. He said the report recommended that every effort should be made to pass the Cullom Bill, and that every effort should be made to defeat the Coudrey Bill. He happened to know, however, considerable about the latter bill, and while there were some features about it that pharmacists could not approve, there were other features that he thought the Association would be very glad to approve.

Mr. Hilton said he would be glad to submit copies of the bills in question to the Section, but unfortunately had no such copies with him, and could not do so at this time.

Mr. Hallberg suggested that the bills were already printed in the "Bulletin."

The motion to refer to the Committee on Education and Legislation was then put to a vote and carried.
The Secretary said he had been requested to call for the report of the Committee on Time and Place of Next Meeting at this time.

Mr. Sayre, of the committee, said that the Committee on Time and Place of Next Meeting were pleased to report that they had received very cordial invitations for the 1911 meeting from St. Louis, Missouri; Rochester, New York; Boston, Massachusetts; Saratoga, New York; Chattanooga, Tennessee; New Orleans, Louisiana; Kineo, Maine; and Cedar Point, Ohio. Mr. Sayre said that he wanted to say in regard to the last-named place that no official communication had been received, but the committee understood that an invitation was extended, and parties were present here distributing badges and asking that the members of the Association vote for Cedar Point, and the committee thought it was best to include that point among the number submitted. He said that the committee further recommended that those persons present that were interested and were prepared to make statements on behalf of their respective localities should be heard at this time. He asked that the committee's report be received without expression of preference as to place of meeting, leaving the Association to decide this matter.

Mr. F. W. Meissner, of LaPorte, Indiana, moved that the report of the Committee on Time and Place be received, and, further, that the Association proceed to choose by ballot the place of next meeting.

Mr. Charles M. Ford, of Denver, said this would take considerable time, as each point named had its advocates and they would want to make speeches. He moved that the report of the committee be referred back to it, and that the committee take it upon themselves to listen to the speeches and present a recommendation.

The Chair stated that, on behalf of the committee, he wanted to say that when Mr. Sayre arrived on the ground he was the only member of the committee present, and most of the communications now before the committee had not been received; that Mr. Sayre stood alone, and it was only last evening that the other members of the committee had put in an appearance. He thought, therefore, the Association should extend some consideration to the committee, for "they certainly were in hard lines."

Mr. H. L. Taylor, of Albany, New York, said he would like to second the substitute motion of Mr. Ford if the mover would allow him to enlarge it. He said Mr. Ford's motion was to refer back to the committee, with instructions to recommend a place of meeting. He would like to add to that, that the President, or the Association, proceed to complete the committee, by naming other members in place of the absentees, so that the Chairman might have a complete committee to act with him. Mr. Ford said he would be glad to accept this suggestion.

Mr. Sayre stated that if it was insisted upon, the committee was ready now to make a recommendation: that he had made this very statement to his colleagues, that a vote without a recommendation would be objected to.
Mr. F. C. Godbold, of New Orleans, said he thought it was proper to state that the papers received by the Chairman of the Committee, Mr. T. W. Jones, of Los Angeles, had been sent to Mr. Sayre, with request that he act as Chairman.

The Chair here suggested that, in view of the statement by Mr. Sayre that the committee was ready now to make a recommendation, if insisted upon, it would be unnecessary to put the motion to refer back to the committee.

Mr. Caswell A. Mayo, of New York, favored the original motion of Mr. Meissner, and said he hoped the substitute motion of Mr. Ford would be voted down. It would require a little time and trouble to ballot, but there were many interests involved, and each member should have an opportunity to express his individual opinion. If the report was sent back to the Committee and it made a recommendation, there would be no choice between places. The mission of the Association was to select a place, and the only way to do that was to have the names from which to select before the members, and let each individual say where he thought the Association should go.

The Chair expressed the opinion that this could be done just as well after the recommendation of the committee was made as any other way—that if the substitute motion was passed, the Chairman of the committee would then recommend a place, and the Association could take any action it saw fit.

Mr. Hallberg, of Chicago, expressed the view that it was the special province and duty of the Committee on Time and Place to consider the advantages and conditions attaching to the several places of meeting proposed, and to see that the proper railway facilities and rates were secured, as also the proper hotel accommodation and rates. These were matters that the Association at large naturally could not go into, and they should carefully sift these things and guarantee the Association against being "held up," as it had been on some former occasions. He thought it was the duty of the committee to make a recommendation, and that it had no right to shift the responsibility on the Association.

The Chair thereupon put the vote on the motion of Mr. Ford to return the report to the committee, with instructions to make a recommendation, and it carried. Thereupon the Chair called upon Mr. Sayre to make a definite recommendation as to time and place of next meeting.

Mr. Sayre said he wished to say that the Committee felt at the time it made its report that it was best not to prejudice the Association by stating any preference, but now that the Committee had been instructed to make such a recommendation, they were prepared to recommend the city of New Orleans as the place of next meeting, and the time as sometime during the month of May.

Mr. Hallberg moved to substitute Boston, Massachusetts, for the recom-
mendment of the Committee, and this motion was seconded by Mr. C. Caspari, Jr., and others.

Mr. Hynson offered as a substitute to Mr. Hallberg's motion that New Orleans, Louisiana; Boston, Massachusetts, and Cedar Point, Ohio, be voted upon, and that the vote be taken by ballot.

Mr. Taylor, of New York, asked how long it had been since the Association had met in Boston and in New Orleans, respectively, and also how long since it had met at Cedar Point. The Secretary replied that the Association had not met in Boston since 1875, thirty-five years ago, and that the last meeting in New Orleans was in 1891. He said it had never met at Cedar Point.

Mr. Patch, of Boston, asked if the Association had not also met in Boston in 1892, but the Secretary said it had not, that the meeting that year was at the Profile House, in New Hampshire, and that the members of the Association went through Boston on the way to the meeting, and were quite royally entertained by the pharmacists of Boston.

Mr. J. M. Good, of St. Louis, said it would take a good deal of time to decide this matter by ballot, and suggested a rising vote instead, and Mr. Hynson accepted the suggestion.

Mr. E. Berger, of Tampa, Florida, took occasion here to remind the members that an invitation had been extended the Association last year, at Los Angeles, to meet in Florida this year, and he wanted at this time to renew that invitation, and in that connection would state that the chief products of his State were oranges and cigars, and both would be free to all whenever the Association came to Florida. He asked that Tampa, Florida, be included in the list of places to be voted for, and the Chair said this would be done.

The Chair thereupon put the vote upon the motion to proceed to an election between the four places named, and it was carried.

Mr. Payne, of Georgia, here asked if it would not be proper at this point to give the members an opportunity to express their reasons for asking the Association to meet at the places of their choice.

Mr. Leo Eliel, of Indiana, asked to be permitted to say a few words here, and he wanted to make this point: That in 1907 the Association met in the City of New York, a very expensive place for the majority of those engaged in the retail drug business; that in 1908 it met at Hot Springs, Arkansas, another very remote point, expensive to reach, and taking a great deal of time of the members. In 1909, he said, the Association met at Los Angeles, California, a point which was beyond the reach of the majority of the members of the Association, who usually attend its meetings. In 1910, the meeting was here at Richmond, "another extreme point." He said he thought the average pharmacist who attends these meetings should have some consideration shown him when the Association came to select a meeting-place for 1911. He thought the most
of those engaged in the practice of pharmacy were interested in having it at a time when they needed a vacation, and he did not think they needed a vacation in the month of May. The reason of the meeting at Richmond at this time was because the U. S. Pharmacopoeial Convention at Washington City was to follow immediately, to which convention many of those in attendance here were delegates. There would be nothing of that kind in May next year, however, and the time that the druggist needs a vacation is in August or September, that being the time when they are worn out by the hot weather of summer and the summer work; and a great many who are accustomed to attend and are interested in the work of the American Pharmaceutical Association are in the habit of postponing their vacation until the meeting of the Association. He also urged that the Association go to some point where it would not be necessary for the average pharmacist to "mortgage his store" in order to meet the rates exacted by the railroad companies and the hotels. Mr. Eliel also urged that the Association should select some place where it could do its work well, and be of some service in carrying out the work the Association was engaged in—some place where, when the members had gone to the meeting and returned, they could feel that they had done some good to the Association, and had received some good from the Association, and had their rest besides.

Mr. Mason, of Detroit, reminded the convention that it was now after 1 o'clock, and there was still much business to be transacted this morning. He thought most of the members were prepared to vote on this question, and he believed that the majority should rule; that discussions should be limited to twenty minutes, and that no one should be allowed more than three minutes in advocating the place of his choice.

There were calls of "Question!" and the Chair put the motion to a vote and it was carried.

Mr. Diehl, of Louisville, moved that the four places in nomination for the meeting place next year be taken one at a time and voted upon, and this suggestion was adopted when it came to a vote.

Thereupon, Mr. F. C. Godbold spoke in advocacy of the claims of New Orleans as the place of meeting in 1911, and the cause of New Orleans was also championed by Messrs. George F. Payne, of Atlanta, and Philip Asher, of New Orleans.

The cause of Boston was championed by Mr. W. C. Alpers, of New York City, and he was supported by Messrs. E. L. Patch, of Boston; C. S. N. Hallberg, of Chicago; C. H. Packard, of Boston, and C. Lewis Diehl, of Louisville.

Cedar Point, Ohio, was championed by Theodore Wetterstroem, of Cincinnati, and the claims of that resort were also advocated by Messrs. Leo Eliel, of South Bend, Indiana; H. T. Hynson, of Baltimore; W. W. Bowman, of Toledo; W. L. Dewoody, of Arkansas, and H. L. Taylor, of Albany, New York.
Mr. Berger put in a good word for Tampa, although he said they did not hope to secure the meeting of the Association there for next year, as they were so close to New Orleans, and he would not ask it; but that they hoped to have the Association at Tampa within the next few years.

The Chair stated that the points to be voted upon, then, were New Orleans, Boston and Cedar Point, and called on all those in favor of New Orleans to rise and stand while the Secretary counted them. This procedure was carried out, and the Secretary announced that New Orleans had received 26 votes. Boston was the next point voted upon in the same way, and the Secretary announced that Boston had received 59 votes. Cedar Point was next, and received 38 votes.

Mr. Payne, of Georgia, moved that as Boston had received 59 votes, a plurality of the votes cast, that Boston be declared the unanimous choice of the Association for its place of meeting in 1911, and this motion was seconded by Mr. Godbold, of New Orleans—who said he thought that all the members should pledge themselves to be at Boston—and was carried unanimously.

The Chair called for the action of the Association as to the time of next meeting, and on motion of Mr. Hynson, of Baltimore, this matter was referred to the Council.

The Chair made announcement that the railway tickets of members which had been deposited for validation were now ready to be returned to them, and could be had at the Local Secretary's desk. He also made an announcement of simultaneous meetings of the Commercial and Scientific Sections at 3 o'clock this afternoon.

On motion, the Association stood adjourned, to meet at call of the Chair.

---

FOURTH SESSION—WEDNESDAY AFTERNOON, MAY 4, 1910.

No business was transacted by the Association previous to the second session of the Section on Scientific Papers and the adjourned session of the Section on Commercial Interests.

---

FIFTH SESSION—THURSDAY MORNING, MAY 5, 1910.

No business was transacted previous to the first session of the Section on Education and Legislation and the first adjourned session of the Section on Scientific Papers.

---

ADJOURNED (SIXTH) SESSION—THURSDAY MORNING, MAY 5, 1910.

An adjourned session of the second general session was held at call of the President on Thursday morning, immediately following the first session of the Section on Education and Legislation, President Rusby presiding.
The Chair stated that as this was an adjourned session the minutes of the second general session would not be read, nor would the minutes of the Council be read.

The Chair stated that the first order of business would be the appointment of the Committee on Pharmaceutical Syllabus, provided for by the amendment to the By-Laws at Wednesday morning's session, and he would appoint the following on that Committee:

- For 7 years, Willis G. Gregory, Buffalo, New York.
- For 6 years, C. S. N. Hallberg, Chicago, Ill.
- For 5 years, Geo. M. Beringer, Camden, N. J.
- For 4 years, Harry B. Mason, Detroit, Mich.
- For 3 years, Eugene G. Eberle, Dallas, Texas.
- For 2 years, Charles Caspari, Jr., Baltimore, Md.
- For 1 year, Henry L. Taylor, Albany, N. Y.

The Chair announced a meeting of the Syllabus Committee at 8 o'clock this evening, if it was possible for its members to get together.

The Secretary was here given opportunity to read several communications which he had received, and he stated he had three telegrams which had arrived since yesterday, in reply to telegrams sent by him by direction of the Association. The first was from Baltimore, which read as follows:

Chas. Caspari, Jr., Jefferson, Richmond, Va.
Reciprocate fraternal greetings, regret I cannot be with you.

Charles E. Dohmf.

The second was from Dean Wulling, of Minneapolis, as follows:

Minneapolis, Minn., May 4, 1910.

Chas. Caspari, Jr., Secretary American Pharmaceutical Association, Hotel Jefferson, Richmond, Va.
Gratefully appreciate sympathy, heartiest greetings and best wishes, successful meeting.

Fred'k J. Wulling.

The Secretary then read the following telegram from ex-President Oscar Oldberg, of Chicago, now sojourning in California for the benefit of his health:

La Jolla, Cal, May 4, 1910.

Charles Caspari, Jr., General Secretary American Pharmaceutical Association, Richmond, Va.
Heartiest thanks to officers and members for remembering your absent brother, although temporarily separated by thousands of miles we stand firmly together in our devotion to true pharmacy.

Oscar Oldberg.

The Secretary read the following communication from Mr. Geo. M. Beringer, offering his resignation as a member of the Committee on U. S. Pharmacopoeia:
To the Officers and Members of the American Pharmaceutical Association:

Gentlemen: In conjunction with the report of the Committee on U. S. P., I herewith present my resignation as a member of the Committee, and urge that this be immediately accepted, and the vacancies existing be promptly filled so that the Committee may be reorganized before leaving Richmond and the work be continued without interruption.

Yours fraternally,

GEORGE M. BERINGER.

The Chair stated that it was with the greatest regret that he heard this resignation presented. He said he did not think any member of this Association since his connection with it had done more faithful, more efficient work or harder work than Mr. Beringer had done as Chairman of that Committee, and that all must appreciate the time and labor he had given to it, and the only reason he would advise not to promptly decline his resignation was because of Mr. Beringer’s statement that he could not afford to give the time to it, and the Association did not want to be unjust. He said he was sure that the Association appreciated the work that Mr. Beringer had done more than he could express. (Applause.)

Mr. Mottinger, of Washington City, moved that the thanks of the Association be returned to Mr. Beringer for his excellent work on this committee, with the assurance that the Association regretted exceedingly that the necessity of his devoting more attention to his private affairs impelled him to take this step.

This motion was seconded by Mr. Raubenheimer, of Brooklyn, and carried unanimously.

The Chair stated that the new appointment on the committee would be named at the next session.

The Secretary stated that he had just received a telegram which, though it had arrived a little late for the purpose, he thought it was proper to read, as it showed the feeling of the New Orleans people towards the Association. Of course, as the place of meeting next year had been settled on yesterday, this communication was no longer available, except as an expression of kindly feeling. He then read the following:

NEW ORLEANS, LA., MAY 4, 1910.

CHARLES CASPARI, JR., SECRETARY AMERICAN PHARMACEUTICAL ASSOCIATION, JEFFERSON HOTEL, RICHMOND, VA.: 

Louisiana Pharmaceutical Association extends fraternal greeting, best wishes successful meeting; earnest desire to have you May, 1911.

C. W. McDUFF, SECRETARY.

The Chair called for the reading of reports of committees as the next order of business, but the Secretary suggested that some of the delegates from the American Medical Association were present, and had with them a communication in regard to the National Formulary. He thought it would be well to call on Doctor Robert A. Hatcher at this time. Thereupon the Chair invited Doctor Hatcher to present his message from the American Medical Association.
Doctor Hatcher submitted the following report on behalf of the committee:

COMMUNICATION FROM THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association has been requested to co-operate in the revision of the National Formulary, and in pursuance of that request the following committee has been appointed: Hatcher, Howland, Hunt, Kebler and Sollmann. The Chairman of the Section on Pharmacology has appointed a committee with the same membership to co-operate with the Committee of Revision of the National Formulary of the American Pharmaceutical Association.

No specific matter was submitted to the committee, and at present it can only report its attitude towards certain questions of general policy, those of admissions and nomenclature being the most important by far.

The committee believes that the usefulness of the National Formulary to the medical profession depends upon the adoption of standards as high as those which the Council on Pharmacy and Chemistry has set for the admission of proprietary products into New and Non-Official Remedies.

The spirit of Rules 8 and 10 should be observed particularly with reference to articles admitted to the National Formulary.

It should be remembered that Rule 8 requires that the trade name of a pharmaceutical preparation must be so framed as to indicate the most potent ingredients. In order to comply with the spirit of this rule the presence of narcotic drugs should be suggested at least by the title, and a preparation of alkaloids should not be called by the name of the crude drug yielding those alkaloids.

Rule 10 states that no article will be recognized by the Council if the preparation is useless or inimical to the public or the medical profession owing to the unscientific composition of the preparation.

The Council holds that all preparations of doubtful medicinal value, but which tend to encourage the use of alcohol or other habit forming drugs, are barred by this rule. Examples of this are found in the compound elixir of celery, elixir of sodium bromide and many others which can be replaced by extemporaneous prescriptions without trouble. It is hardly necessary to state that such preparations as the compound elixir, which the Council has condemned unequivocally, are excluded by this rule also.

The foregoing report having been adopted by the Council on Pharmacy and Chemistry without a dissenting voice, the committee hereby tenders its services in compliance with the request made at the meeting of the American Medical Association at Atlantic City in June of last year.

R. H. Hatcher, Chairman of the N. F. Committee A. M. A.

Doctor Hatcher stated that this report was made to the Council on Pharmacy and Chemistry, and he read it merely to suggest the attitude of that committee, and to ask the pleasure of the Association in regard to further co-operation, and to indicate the way in which any co-operation might be desired pharmaceutically.

The Chair stated that while he did not wish to discuss this report, he would like very much to direct attention to its great importance. He said that the idea of a national formulary's emanating from one single association of one profession, without any co-operation on the part of the medical profession, was, in his opinion, an absurdity, and one that could never be sustained at law. He said if hearty co-operation could be had
between the professions of pharmacy and medicine in the preparation of the National Formulary, it would at once give it a standing such as it would not have coming from one organization alone. He thought that was a good reason why the Association should welcome this communication from the American Medical Association.

Mr. Beringer moved that this communication be received, with thanks, and referred to the Committee on National Formulary, and that the cooperation of this committee of the American Medical Association be solicited throughout the work of revision. This motion was seconded by Mr. Meissner and others, and carried unanimously.

The Chair stated that reports of committees were now in order, and asked if the Committee on President’s Address was ready to make report. Mr. Beal, Chairman of the Committee, answered in the affirmative, and Second Vice-President Johnson was called to the Chair while the committee made its report.

Mr. Beal prefaced the reading of the report by stating that the committee had found, on consideration of the President’s Address, such a wealth of material and of ideas that it had felt itself at a great disadvantage, and appreciated that the report made is not in accordance with the character of the address itself, or that it fully covers the many new and original thoughts which were presented in that address. He then presented the report as follows:

REPORT OF COMMITTEE ON PRESIDENT’S ADDRESS.

Mr. President: The committee to which was referred the recommendations contained in the President’s address respectfully reports as follows:

In the opinion of the committee your President is entitled to the thanks of the Association for the frank and fearless manner in which he has discussed matters which are of vital concern to the Association and to the cause which it represents, irrespective of our agreement or disagreement with the opinions expressed by him.

With respect to the specific recommendations contained in the address we report as follows:

We approve of the recommendations concerning increase in membership in so far as they refer to

1. The creation of a class of members to be known as sustaining members, or by some other appropriate title, the same to be provided for under Rules and By-Laws of the Council and hereafter submitted for the approval of the Association.

2. The establishment of new Branches in districts which are able to maintain them in proper efficiency, and to increase the efficiency and working force of the Branches already established.

3. The authorization of such changes in the character and scope of the “Bulletin” as will justify a reasonable expectation of an increase in its circulation and influence among non-members and make it as far as possible self-sustaining.

The committee does not approve the proposition to use the income from the Ebert legacy prior to the time when the fund and the accumulations thereon shall have reached the gross sum hitherto fixed by resolution of the Council. We therefore recommend that this particular recommendation of the President be sent to the Council for further consideration.
The committee approves of the following recommendations:

4. To increase the working efficiency of the important committees of the Association by such liberal allowances of financial support as the funds of the treasury may now or hereafter warrant.

5. That the Committee on National Legislation be supplemented and strengthened by the addition of sub-committees closely allied with the work of the various State Pharmaceutical Associations.

6. That the work of the Committee on Publicity be supplemented and strengthened by the addition of sub-committees located in the principal centers of population.

7. That the Committee on National Legislation inquire into the desirability and practicability of the establishment of legal requirements for proper educational and technical qualification of those who are directly in charge of the importation and wholesaling of drugs and chemicals, in order that the public health may be more properly safeguarded.

8. The recommendation that all ex-Presidents be made ex-officio members of the Council being one which involves an amendment to the fundamental laws of the Association, and a proposition of such far-reaching possibilities, we recommend that it be sent over to the Council for further consideration.

9. We approve of the President's recommendation that all committees and officers having charge of the arrangements for future meetings be instructed to make greater efforts to secure more favorable rates for transportation and hotel accommodations, and that the committee should as far as possible avoid the selection of expensive hotels as headquarters.

10. We approve the recommendation that the Association place itself on record as endorsing the statement contained in the Sixth Revision of the United States Pharmacopoeia, "That it is best to refrain from dropping (from the official list) drugs and preparations which on inquiry are found to be of more than purely local use," and that the primary consideration in determining the official recognition of a medicinal article should be that it or its preparations are of common occurrence in pharmacy rather than mere academic opinions concerning therapeutic value.

11. We also concur in the opinion of the President that the definitions, descriptions and tests of pharmacopoeial articles should be so fully and definitely stated as to insure as far as practicable against the possibility of their misinterpretation, and also that it would be advisable to include in the text of the Pharmacopoeia descriptions of the more important powdered drugs in so far as the inclusion of such description is capable of practical usefulness.

In addition to the specific recommendations sent to this committee for consideration we also find in the President's address various expressions of personal opinion upon questions and policies concerning which reasonable men may justly and honestly differ.

The committee therefore deems the present occasion opportune for the reassertion of the right of every member to the free expression of his personal opinion regarding any question of vital concern to pharmacy or to the welfare of this Association, and also of the fact, founded upon the constitution and long-established Association tradition, that no such assertion of personal opinion, whether of officer or of lay member, can be regarded as reflecting the Association policy regarding such question, unless the same shall have been clearly expressed and ratified by concurrent vote of the Council and general session of the Association in the formal manner provided in the Constitution and By-Laws.

Respectfully submitted,

J. H. Beal,
F. C. Godbold,
Caswell A. Mayo,
Charles Holzhauer,
Henry C. Blair.
Mr. Beal, in connection with recommendation three of the committee's report, explained that the committee felt that the action of the Council as to the Ebert Legacy, expressed by resolution, was the result of careful and deliberate thought on the part of that body, and that the Association in general session, where there was not sufficient time for a consideration of all the points involved, should hesitate to reverse this action of the Council. Therefore, the committee had reported in favor of referring to the Council this particular recommendation of the President, which should be sufficient notice to the Council that the Association desired it should again give the subject full consideration, and report at some future time.

Mr. Beal stated that, on behalf of the committee, he would like to move that the report be adopted and the committee discharged. Mr. Whelpley seconded this motion.

The Chair called the attention of Mr. Beal to the fact that at the Los Angeles meeting last year the name of the Committee on National and State Legislation was changed to that of Committee on National Legislation only, State legislative matters to be taken care of by the Section on Education and Legislation.

Mr. Beal, in reply to the statement of the chair, said that the Committee had simply followed the nomenclature of the "Bulletin" of the Association, and he was sure there would be no objection to making this change.

President Rusby, from the floor, stated that Mr. Beal was perhaps not in the room a few minutes ago, when the President acknowledged he had made an error in this behalf; that it was his fault, and that he would assume the responsibility for it.

Mr. Beal said that, if there was no objection, he would assume the responsibility of changing the title in the report to correspond to the correct title.

Thereupon, the Chair put the vote on the motion to adopt the report and discharge the committee, and it prevailed.

President Rusby resumed the chair, and stated that he did not know that a President had ever done such a thing before, but in view of certain peculiar conditions existing at this time, with which many of the members were familiar, he wanted to express his gratitude to the committee for the manner in which they had presented their report; that the courtesy and consideration they had shown had won his gratitude, and he hoped the committee would accept his thanks.

Mr. Taylor, of Albany, commented on the failure of the Committee on President's Address to take any action upon the last recommendation made by the President, that the proper academic and professional titles of members be appended to their names in the official directory. Mr. Taylor spoke at length upon the question of degrees and titles, and the inconsistencies and shortcomings of editing rules in general in this country, and moved the appointment of a committee to consider the desirability of
attempting to secure some concerted action in this Association along the line of editing rules.

This motion had a second in Mr. Hynson, of Baltimore.

The Chair said that he understood Mr. Taylor's position to be, that he desired to extend the subject of degrees to the subject of editing rules in general.

Mr. Remington stated that in the pharmacopœial work of the Committee on Revision they had been met with this same difficulty, and he thought it could be easily solved. There is sent to each member of the committee a short notice, stating that it is proposed to put one title after each member's name in the Pharmacopœia, and it is desired to give the member himself an opportunity to say which title he prefers, and he is given the benefit of his title in the Pharmacopœia. The committee had found this a simple and safe rule. The idea is to give a man one title, and give him the privilege of saying what that title shall be.

The motion to appoint a Committee on Editing Rules was put to a vote and carried, and the Chair, a little later in the session, appointed the following as composing that committee, stating at the time that it might look "a little like mixing fire and water," but he believed the various interests should be represented on the committee—the editor of the "Bulletin," the Chairman of the Revision Committee, and the mover of the resolution:

H. L. Taylor, Albany, N. Y.
C. S. N. Hallberg, Chicago, Ill.
Joseph P. Remington, Philadelphia.

The Chair stated that the Committee on Drug Reform had a report to present—a long one—and in order to avoid useless consumption of time, the report being in print, it would be distributed by the Chairman, and he would ask the members to read it over, so that when it came up for discussion on Saturday it would not be necessary to read the report before the convention. He said this report would be presented by Mr. Sayre, its Chairman.

Mr. C. M. Ford, of Denver, stated that, before leaving the subject of the President's Address, he would like to read some resolutions, suggested by the Chairman's Address, and somewhat supplementary of the report of the Committee on President's Address:

Resolutions.

Resolved, That in the opinion of the American Pharmaceutical Association it is neither wise nor expedient, even in pursuit of schemes which it is claimed will advance the material welfare of dispensing pharmacists, to assail, antagonize or malign any class inseparably joined to us by commercial or professional ties.

Resolved, That we seriously deprecate the hostile attitude towards the medical profession and the jobbing fraternity of various drug journals assuming to represent pharmacists in general, or some considerable body of pharmacists in particular.
Resolved, That we respectfully urge upon the officers of the American Druggists' Syndicate a more careful supervision of the utterances in their so-called organ. Its harsh language is hurtful to pharmacists, and embarrassing in their necessary relations with one another, and with physicians and jobbers. The mercenary schemes of the few over-zealous and adventurous individuals, who being frequently without any training in pharmacy, and who have entered its ranks solely for gain and to exploit their peculiar ideas of high finance, can have no sympathy with its aims or traditions—such schemes can be helpful and profitable to only an insignificant few, and must necessarily bring inevitable disappointment and disaster to the multitude who follow in their train.

Resolved, That we recommend that any movement for the reform of medical practice be allowed to originate and proceed within the medical profession.

Resolved, That we are opposed to any attempt upon the part of the pharmacal press to dictate or compel any such reform, believing as we do that the medical profession is eminently qualified to institute and carry out its own necessary reforms.

Mr. Hallberg seconded the resolutions just offered.

Speaking to his resolutions, Mr. Ford said he recognized that they were not as strong as they might be, to suit the ideas of those who had been thinking strongly on these topics, but he also realized that the position of this Association was a delicate one; that when the President's Address was read and talked over, it was feared that the Association might be betrayed into some expression which was contrary to its ethical ideals, or which might detract somewhat from the dignity and character it had always enjoyed. But the condition of its members throughout the country was a matter that must have consideration now. They certainly had been made to suffer by misrepresentation of the grossest and vilest kind, in certain pharmaceutical literature, and they had to be constantly on the defensive against these papers and utterances, in the attempt to show that they did not apply to the great mass of druggists, but only to the few. Whatever the motive might be, it was wrong to put the druggists of the country in this false attitude, and force them to be constantly trying to square themselves with the medical profession for things said in anger and said without reference to their application to druggists as a class.

Mr. Francis B. Hays, of New York, ventured the prediction that if this question were to come up for discussion there would be a great many members who would take one side or the other, and he, therefore, with all due consideration to his friend Mr. Ford, moved to lay these resolutions on the table. This motion was seconded by Mr. Hynson, of Baltimore.

The Chair put the vote on the motion to lay upon the table, and, on division, the Secretary announced that 32 members had voted in favor of the motion to lay on the table, and 33 against said motion, and the Chair declared the motion lost.

The Chair thereupon put to a viva voce vote the motion to adopt the resolutions presented by Mr. Ford, and it carried, and the resolutions were declared adopted.

Mr. Beringer offered the following resolution:
WHEREAS, The American Pharmaceutical Association through its various committees on U. S. Pharmacopoeia, National Formulary and Standards for Non-Officials, is engaged in scientific investigations tending to the fixing of correct standards for many drugs, pharmaceutical preparations and chemical products, and

WHEREAS, A number of our active members, connected with the work of the various departments of the Federal Government, are associated in the work of these committees and have at their command much useful data that should be available and would materially assist in the work of our committees; therefore, be it

Resolved, That the co-operation of the departments of the U. S. Government be solicited, and be it further

Resolved, That a formal request be made by the executive officers of this Association, that such members who are in the Government service be permitted to serve on these committees, and to utilize such scientific and practical information as will aid in our work without being detrimental to the interests of the Government.

Mr. Beringer explained that, by rule of some of the departments, those engaged in the Government Service were permitted to make no disposition of the material which they had gathered and the information obtained, and reminded the Association that of the Committee on U. S. Pharmacopoeia of this Association and that on National Formulary for this year twenty per cent. or more of the members were engaged in the Agricultural and other departments of the Government Service, and likewise as to the Committee on Standards of Non-Officials. He said he believed these gentlemen should be permitted to co-operate with the American Pharmaceutical Association in its scientific work, and without this request he did not believe the Association could have the advantage of the valuable information that these gentlemen possessed.

The resolution was promptly adopted.

The Secretary suggested that the report of the Committee on Weights and Measures, Mr. Henry Kraemer, Chairman, might be made at this time, and Mr. Kraemer presented the following report:

REPORT OF COMMITTEE ON WEIGHTS AND MEASURES.

A number of suggestions have been made by the members of the Committee which are in the line of educational propaganda work.

Professor Stevens suggested the preparation of a newsy article on the Metric System showing its simplicity and stating its legalized use for different purposes by the Government, and proposing that such article be sent to a progressive pharmacist in each of our principal cities asking him to send it to the daily newspapers with the request that it be published.

Professor Asher recommended that an article on the Metric System be prepared, showing its advantages from the manufacturing standpoint, and that a copy of the article be sent to every pharmaceutical association, branches of the A. Ph. A., and certain allied associations.

Dr. S. W. Stratton, Director of the United States Bureau of Standards, Department of Commerce and Labor, Washington, D. C., furnished the chairman, at his request, a pamphlet on "The International Metric System of Weights and Measures," which was expressly prepared to answer some of the more simple questions addressed to the Bureau of Standards in regard to the Metric System and its use. This pamphlet gives a concise
history of the Metric System, the names of the countries giving governmental support to the system, a synopsis of the system, and tables and diagrams showing a comparison of Metric and customary units. And it is believed that this pamphlet would furnish an excellent basis for an article intended for educational purposes, whether circulated among pharmacists, physicians or others.

The Bureau of Standards has also gotten out a large chart showing the relation of the three Metric units to one another, and in turn to the customary units employed. This chart would be especially useful in schools of pharmacy and medicine, and in other educational institutions where the subject of weights and measures is taught.

In fact, the chairman is of the opinion that most effective educational work leading to the general approval of the Metric System can be accomplished by getting teachers in the public schools to lay more stress on the advantages of the Metric System, and to give practical exercises using the actual measures and weights. In fact, the question of the adoption of the Metric System universally in the United States could not long be delayed when once the pupils in our schools have learned to actually use metric weights and measures.

It is rather remarkable that, as shown in the pamphlet already referred to, when the use of the Metric System is required in the Medical Departments of the Army and Navy, and in the United States Public Health and Marine Hospital Service, and besides legalized in the Philippine Islands and made obligatory in Porto Rico, there has been adopted in the Senate of the United States a resolution entitled S. J. Res. 37 (Congressional Record, March 11, p. 3121), which is under the consideration of the Committee on Printing. This resolution provides that all documents, papers, etc., published by the government of the United States be printed in the English language and includes provisions that wherever Metric weights and measures, Centigrade thermometer and similar standards are used, the equivalent in the English standard be given.

This resolution scarcely needs other comment than to say that the necessity exists for guarding the progress that has already been made.

A similar back tendency in certain directions is shown by a recent editorial in American Medicine (January, 1910, p. 7) on “The Tyranny of the Metric Advocates and French Metric Tyranny.” While the percentage of physicians who actually use the Metric System in prescription writing is very small, it is probable that the majority of them recognize its advantages, and hence it may be taken for granted that this editorial will not have any real influence in hindering progress.

As showing what may be done by local branches of the A. Ph. A., attention is called to the action of the Chicago Branch which proposed two resolutions for submission to the National Convention of City Sealers which met in Washington on February 25th. (See A. Ph. A. Bulletin, February, 1910.)

A. B. Stevens,  
Charles E. Caspari,  
Philip Asher,  
John J. Brinton,  
Henry Kraemer, Chairman.

The following article which has been prepared by Professor Stevens gives succinctly some facts about the Metric System which are not generally known:

Metric weights and measures were legalized in the United States in 1866. They were adopted in 1893 as the fundamental standard by which all other weights and measures are verified.

United States postal rates to foreign countries are based on Metric weights, for which purpose 15 grams shall be considered equivalent to half an ounce.
They are used in the United States Mint. The weight of one dollar is 26.729 grams, the half dollar 12.5 grains, the quarter 6.25 grams and the dime 2.5 grams.

The legal electrical unit is based on the Metric System.

They are required to be used in the work of the Navy and War Departments. Invoices, requisitions, receipts and prescriptions must be written in the Metric System.

Their use is required in the Public Health and Marine Hospital Service for all official, medical and pharmaceutical purposes.

There is no definite relation between the old system of weights and measures. The avoirdupois ounce has 437.5 grains, the apothecaries' ounce has 480 grains, and the fluid ounce of distilled water weighs 455.7 grams. Compare this with the Metric System in which one cubic centimeter of distilled water weighs one gram.

The system is so simple that anyone may become familiar with it in a short time. Like our decimal currency the tables contain terms that are seldom used. In currency dollars and cents are all that is necessary, though the dime is frequently used, mills only occasionally, while eagles and double eagles are almost unheard of.

For metric weights all that are important besides the gram are, the kilogram which is 1000 grams and the milligram which is 0.001 of a gram. The decigram, 0.1 gram, and the centigram, 0.01 gram, are occasionally used. For measures of capacity the cubic centimeter and the liter, which is 1000 cubic centimeters, are all that is necessary. For measures of length the meter is the unit. The kilometer is 1000 meters, the decimeter is 0.1 of a meter, the centimeter is 0.01 of a meter and the millimeter is 0.001 of a meter.

For those who have to use the system all that is necessary is to obtain the required weights or measures and use them where directed. It is stated that a large shop received a contract for a bridge the dimensions of which were in the Metric System. The men at first refused to do the work, but when given metric measures soon became familiar with them, and later acknowledged that they were easier to use than the old system.

A. B. Stevens.

The Chair stated that this was another report that proved good work, and called for action. On motion of Mr. Sayre, the report was ordered received, and to take the usual course.

In the absence of Mr. Wulling, Mr. Joseph W. England, of the Committee, presented the report of the Chairman of the Committee on "Bulletin," as follows:

REPORT OF THE CHAIRMAN OF THE COMMITTEE ON BULLETIN, A. PH. A.

To the American Pharmaceutical Association:

Gentlemen: The closing year's activities of your Committee have crystallized into the following recommendations, which if adopted and carried out by the Association, would, in the opinion of the committee, greatly add to the efficiency and value of the Association, to its members and to pharmacy at large:

The Committee recommends that

1. The Association establish a monthly journal of proper size and character to take the place of the present "Bulletin."

2. That the title of the journal be "The Journal of the American Pharmaceutical Association."

3. That the scope of the proposed journal include editorials, original articles and proceedings (annual, Council and Branch), and pharmaceutical abstracts (covering the former Report on the Progress of Pharmacy).
4. That only approved papers and advertisements be accepted for publication in the proposed journal.

It has also been proposed by a member of the committee that the editor be the editor-in-chief; the General Secretary an associate editor (to report the Proceedings); and the Reporter on the Progress of Pharmacy an associate editor (to report the pharmaceutical abstracts), the last named to have eight or more assistant editors according to the work to be covered.

The chairman is conscious of the importance and nature of these committee recommendations and, in order to facilitate their discussion by the Association, he appends abstracts from the discussion of the subject by the committee members, who have given the matter much thought and consideration.

The adoption of the first recommendation was unanimous and practically without discussion. The other recommendations were adopted by a majority of the Committee. Abstracts of the Committee discussion follow. In support of the second, third and fourth recommendations, Mr. J. W. England who made them says:

"Personally, I do not favor the recommendation that the Report on the Progress of Pharmacy be issued annually in the form of a bound volume, this volume and the "Bulletin" to take the place of the Proceedings as published heretofore. I believe the journal should report all the activities of the Association work. It is doubtless more convenient to have in one annual bound volume the Report on the Progress of Pharmacy than in twelve parts, but on the other hand there are some very distinct compensating advantages: (1) The subject matter would be much more recent and up to-date and, therefore, much more valuable (some of the matter in the 1908 Proceedings was over one year old when published); (2) By concentrating all the printed matter of the Association in one volume, considerable saving would result to the Association for binding, mailing and express; and (3) The monthly journals would then be sufficiently valuable to induce the members to save and bind them. As it is now, the "Bulletin" duplicates a part of the matter of the Proceedings and is thrown away when the members receive the Proceedings.

"The experience of the American Chemical Society in the publication of their journal and Chemical Abstracts is very suggestive. In size, their Journal and Abstracts are 6\(\frac{1}{2}\)" x 9\(\frac{1}{4}\); our Proceedings and "Bulletin" are 5\(\frac{3}{4}\)" x 8\(\frac{3}{4}\); this is only one-half inch more in width and one-fourth inch longer in the size of the page, but it makes a much better appearing page and gives tabular work better display. The type is 10 and 8 points in both cases with slightly different faces. In 1909, the Journal of the American Chemical Society published 4600 copies, embracing 1482 pages of reading matter or about 128 pages per month at a cost of $6,314.34; the editor's salary being $650.00 extra. (Journal of the American Chemical Society, February, 1910, page 20.) The Society publishes also two other journals—Chemical Abstracts issued every two weeks and the Journal of Industrial and Engineering Chemistry issued every month. The annual dues of each member is $10.00 and he receives all three publications. Formerly, it was $5.00 and he received only one—the Journal. The receipts from advertisements from all three publications were $6,551.00, the Journal receiving about one-fourth of this or $1,660.00.

"If it were possible for the A. Ph. A. to issue a monthly journal of 128 pages, 88 pages of this could be given over to the editorials, original articles read before the Association and its Branches, and the proceedings of the Branches; and the other forty pages to pharmaceutical abstracts. 88 pages for general subjects would probably be sufficient, because a part of the Proceedings is now duplicated in the pages of the "Bulletin." There would probably be at least 32 pages or more available for new matter each month. The yearly number of pages would be 1536.

The Proceedings of the A. Ph. A. for 1908 numbered 1200 pages, of which only 441 pages were occupied by the Report on the Progress of Pharmacy. In 1907-8 the Pro-
ceedings cost $4,244.00 including the salary of the reporter on the Progress of Pharmacy of $750.00. (Proceedings A. Ph. A. 1908, 467.) The "Bulletin" this year will cost $2,000.00 including the editor's salary of $200.00. In other words, we spent $5,750.00 ($4,250.00 + $1,500.00) in 1908 for both publications for about 2000 members—the 2500 members of 1909 will cost easily $6,250.00, while the American Chemical Society spent for its Journal in 1909, for 55 per cent. of its 4600 (2530), the equivalent of only $3,465.00. Of course, 2530 copies of the Journal would have cost more than this, because the saving on the smaller number of copies of the Journal would be for work and paper only, and not for composition. The composition would have cost the same for 2530 copies as for 4600 copies. Hence, $1,000.00 probably should be added to the $3,465.00 ($4,465.00), and if to this we add $1,500.00 for editorial salaries, our publications would cost us practically $6,000.00; and if $1,500.00 was secured for advertisements, the gain would be $1,750.00. This is not unreasonable to believe when we remember that in 1907-8, the binding alone cost $420.00, and the expressage, etc., was $502.00, and we would save over half these sums if the Proceedings or the publication were issued monthly and mailed under second class postage. But even if no advertisements were secured and no saving made, the gain to the Association in efficiency of work and in stimulating increased interest among the members would, in my judgment, justify the change.

"I am informed on good authority that, if the American Pharmaceutical Association wishes it, the American Chemical Society might be willing to have its abstractors gather for its abstracts of chemical articles of pharmaceutical interest (Prof. A. B. Stevens, who is the editor of the division of pharmaceutical chemistry, could doubtless advise us along this line). It might be possible, also, for us to make a working arrangement with the Journal of the A. M. A. for medical abstracts of pharmaceutical interest, and possibly with other technical journals in special fields—botany, biology, physiology, etc."

Mr. George M. Beringer says among other things: "I find it is valuable indeed to have before me in the form of annual proceedings the history, discussion, motions and all information relating to committees, duties and matters that have been presented in the form of papers, resolutions, etc., for continual reference. The Proceedings as now published form a continuous history of the A. Ph. A. and all of its activities, and for this particular reason, I hope that the plan of publishing this annual volume of Proceedings will be continued without change."

Mr. C. S. N. Hallberg writes: "Since I am fully convinced that nothing short of a first-class journal will maintain interest in the Association and promote its cause, I am in favor of Mr. England's plan. This year will see most of the members at the annual meeting without having scarcely gleaned the bound report of last year's meeting. There is no use of postponing the time (for beginning the proposed enlarged journal to record all the activities of the Association) except in so far as may be required to compromise with the present year's publication."

Mr. F. W. Meissner in advocating the recommendations made the suggestion to bind a sufficient number of sets of the Journal at the end of each year for such members who desired to purchase bound volumes in preference to saving the monthly numbers and having them bound themselves.

The chairman is convinced that the Association should have one publication in the form of a strong and representative monthly, and possibly later a bi-monthly, journal. A properly conducted Association journal, sufficiently representative and of wide enough scope, is the one essential required to strengthen the Association. The objection to the discontinuance of the Proceedings and report in separate volumes are such as are overcome by the suggestion of Mr. Meissner, to have the Association issue at the end of each year bound volumes of the journal for those who care to have them. Mr. Meissner's suggestion appears to the chairman to be an excellent one, in that it makes
it possible for those who do not care to save and bind the separate numbers of the journal, to procure bound volumes covering the entire activities of the Association at the end of each year, thus making it possible to continue the custom observed by many in the past of adding annual volumes to their library.

Frederick J. Wulling, Chairman.

Minneapolis, Minn., April 30, 1910.

Mr. England said that the other members of the Committee, except Mr. McElhenie, had had a conference since coming to this meeting, and wished to present the following brief supplementary report:

SUPPLEMENTAL REPORT OF THE COMMITTEE ON BULLETIN.

Richmond, Va., May 4, 1910.

American Pharmaceutical Association:

Gentlemen: As members of the committee we endorse the report of the Chairman of the Committee on Bulletin submitted, but wish to present certain additional facts and recommendations:

In the first place we are most surprised to find, on investigation, that the expenditures of the American Pharmaceutical Association for its publications have risen year by year. from $3,895.00 in 1905-06 to $7,800.00 in 1909-10, an increase of $3,905.00, or 100 per cent. The increase of membership during the same period has been from 1,868 to 2,500, an increase of only 34 per cent.

Expenditures in Detail of the Publications of the A. Ph. A.

Increase in five years ................. $3,905.00, or 100 per cent. increase.
Members 1905-06 ....................... 1,869,
Members 1909-10 ...................... 2,500, or about 34 per cent. increase.

The seriousness of the situation becomes apparent when we realize that our membership dues, to-day, are not sufficient to pay our yearly expenses. Hence it is very evident that retrenchment of expenses should be made, if at all possible, and if we can issue our publications at a less expense than formerly, as we believe, and are prepared to show can be done, we feel that it is our imperative duty to do so.

We have gone very carefully into the question of the expense of issuing a monthly Journal along the lines proposed, and from bids obtained from reliable printers, find that it would be readily possible to issue such a Journal for much less money than our present publications now cost us, probably for several thousand dollars a year less. We now spend $7,800 a year for our publications, and for a much less expenditure, we could do the same work in the form of a monthly Journal, and could do it much better.

Our Journal would then go, every month, to the rank and file of our membership, inspire attention and interest, and promote more general and aggressive work. Such a Journal could be made a power in the land for good to every legitimate pharmaceutical
interest. In our judgment, the American Pharmaceutical Association will never command the influence it could or should until it has an official organ of its own, analogous, for example, to the Journal of the American Medical Association. Before this latter association had its own official organ, its membership was small, and its influence limited. Since the establishment of its Journal, it has grown in membership by leaps and bounds, and its influence has become potential.

What is true of the American Medical Association is true also of pharmaceutical organizations generally abroad; they all have their own official organs, and they exert a wide influence.

If the American Pharmaceutical Association looks with favor upon the establishment of a monthly Journal, we would recommend that the subject be referred to the Council with power to act, to arrange all details as to the issuance of the Journal, including election of editors, etc.

We have not mentioned the matter of advertisements for the Journal, but we believe that sufficient advertisements of the proper character could be obtained to make the Journal in time practically self-supporting. Then the money received from dues, and used to pay the expenses of these publications, could be used for other purposes which would materially increase the work of the Association, and extend its influence.

(Signed)  
J. W. England, Acting Chairman,  
Geo. M. Beringer,  
C. S. N. Hallberg,  
F. W. Meissner, Jr.

Mr. Beal moved that this very excellent report be referred to the Council, with power to act in the premises, and this motion was seconded by Mr. Asher and carried without dissent.

The Secretary read the following telegram addressed to Philip Asher, of New Orleans, asking the endorsement of this Association of New Orleans as the proper site for the World’s Panama Exposition, to be held in 1915:

NEW ORLEANS, LOUISIANA, 5-4-1910.

Philip Asher, J. H., Care of Convention of American Pharmaceutical Association:

You are earnestly requested to secure adoption of resolutions by the Pharmaceutical Association endorsing New Orleans as logical point for World’s Panama Exposition.

Norman Walker, Chairman Convention Committee.

On motion of Mr. Hays, this matter was referred to the Council. This concluded the business of the Association at this session, and an adjournment was had, subject to call of the President.

SEVENTH SESSION—THURSDAY AFTERNOON, MAY 5, 1910.

No business was transacted by the Association previous to the second session of the Section on Education and Legislation and the second adjourned session of the Section on Scientific Papers.
Eighth Session—Friday Morning, May 6, 1910.
No business was transacted previous to a joint session of the Section on Education and Legislation with the Boards of Pharmacy and Pharmaceutical Faculties.

Ninth Session—Friday Afternoon, May 6, 1910.
No business was transacted by the Association previous to the first session of the Section on Practical Pharmacy and Dispensing.

Tenth Session—Friday Evening, May 6, 1910.
No business was transacted by the Association previous to the second session of the Section on Practical Pharmacy and Dispensing.

Eleventh Session—Saturday Morning, May 7, 1910.
No business was transacted by the Association previous to the third session of the Section on Practical Pharmacy and Dispensing and the first (and only) session of the Section on Historical Pharmacy.

Twelfth Session—Saturday Afternoon, May 7, 1910.
President Rusby called the Association to order in final session at 3 o'clock p. m., and called for the reading of minutes of the second general session as the first order of business. The Secretary read the minutes of the session held Wednesday morning, May 4th, and also the minutes of an adjourned session of the second general session, held Thursday morning. The Chair asked if there were any corrections of the minutes to be made, but none were offered, and they were declared approved as read.

The reading of the minutes of the Council was called for as the next order of business, and Secretary England read the minutes of the fifth session, held on May 5, 1910.

Minutes of the Fifth Session of the Council.
The fifth session of the Council was held May 5, 1910, at 9 a. m., Chairman Godbold presiding. Present: Messrs. Godbold, Eliel, Day, Asher, C. Caspari, Jr., Whelpley, Hunsberger, Scoville, LaPierre, Rusby, Raubenheimer, Motter, White, Eberle and England.

The minutes of the previous meeting were read and approved.
Applicants for membership Nos. 208 to 213, inclusive, were elected.
Mr. Scoville suggested that the Association have official numbered buttons, in lieu of the annual local badge, for members who attend the annual meeting.
The suggestion was adopted, and the General Secretary was directed to so inform the Local Secretary.
Moved by Mr. Whelpley, seconded by Mr. Hallberg, that the time of the annual meeting of 1911 be from August 14th to 18th, inclusive. Carried.
On motion of Mr. Whelpley, seconded by Mr. LaPierre, C. Herbert Packard, of Boston, was elected Local Secretary for the annual meeting of 1911, and the Local Secretary was made Chairman of the Committee on Arrangements, with power to select associates.

Chas. Caspari, Jr., proposed, seconded by Mr. Whelpley, that the Historian of the Association be made a member of the Council ex-officio, and submitted the following amendment to the by-laws, which was agreed to:

Amend Article II, Chapter VII, by deleting the word "and" in the third line and inserting the words, "the Historian of the Association," after the word "Council" in the same line.

Charles Caspari, Jr., spoke upon the subject of the complimentary distribution of the Proceedings of the Association to schools of pharmacy.

Mr. Raubenheimer moved, seconded by Mr. England, that back numbers of the Proceedings shall be supplied to schools of pharmacy only on the payment of the regular prices. Carried.

Mr. Motter requested that the name of the Motter Prize Fund be changed to the College Prize Fund. Agreed to.

Secretary England also read the minutes of the sixth session of the Council, held May 6th, as follows:

MINUTES OF THE SIXTH SESSION OF THE COUNCIL.

The sixth session of the Council was held May 6, 1910, at 9 a.m., Chairman Godbold presiding. Present: Messrs. Godbold, Raubenheimer, Charles Caspari, Jr., Beringer, Whelpley, C. E. Caspari, Koch, Meissner, LaWall, White, Eliel, Day, Asher, LaPierre.

The minutes of the previous meeting were read and approved.

Applications for membership Nos. 214 and 215 were favorably acted upon.

The report of the Committee on Reorganization to the Council was presented as follows;

To the Council of the American Pharmaceutical Association.

The members of the Committee on Reorganization have considered the various recommendations in the very able address by President Oldberg, presented at the last annual meeting of this Association, which was, on motion, referred to your honorable body with the recommendation that it be referred to the Committee on Reorganization.

Your Committee would respectfully submit the following suggestions for your further consideration:

1. Our Publications.—A rearrangement of the present publications would appear to be desired in view of the fact that many items are now published both in the "Bulletin" and in the annual volume of Proceedings, thus entailing an unnecessary expenditure of money.

2. Committees.—We endorse the criticism regarding the need for revising the number and the status of the Committees of this Association, and agree with him in the recommendation that the several Committees should be appointed by the Council, that they be required to report directly to the Council and that such reports as require additional discussion be referred to one or the other of the Sections of this Association for further discussion. Such a procedure would relieve the general sessions of the Association of a tremendous amount of routine work and would insure more careful consideration of the recommendations embodied in the reports of the several Committees.

We also recommend that the Council consider the desirability of rearranging or revising the Committees of this Association so as to avoid, as much as possible, unnecessary duplication by arranging for cooperation on the part of the several Committees.

3. Selection of our Officers.—The criticisms offered, while in a measure justified, hardly warrant the recommendation of a change in the method of our nominating candidates.
for offices, and your Committee would, therefore, recommend that the present system of nomination with election by mail be given a further trial, but that such election take place within three months of the annual meeting at which such officers are installed.

4. Suggestions Regarding our Constitution and By-laws.—Your Committee would submit the following report on the several recommendations:

**Constitution.**

Art. I of the Constitution as it now reads appears to be sufficiently clear to set forth the object of the Association.

Art. III. Your Committee believes that the recommendations regarding a change in the method of preparing abstracts on the Progress of Pharmacy if expedient at the present time would be desirable.

**By-laws.**

Chap. 1, Art. II. Change so as to read, “The names are to be submitted by the General Secretary by mail ‘three months prior to the date of the annual meeting,’ and return the same ‘within two months prior to the date of said annual meeting.’”

Chap. 1, Art. V. The repetition pointed out as being embodied in this article can do no harm, as it emphasizes a fact. The editor should be included.

Chap. 2, Art. IX. The recommendation that the President should be required to discuss questions bearing on the affairs of the Association is desirable, when expedient, and the article should be changed so as to read, “He shall present an address on the affairs of the Association” and events of the year, or discuss, etc.

Chap. 4, Art. II. The duties of the Local Secretary are sufficiently well defined in this article as it now appears.

Chap. 5, Art. III. Your Committee agrees with the suggestion that it is neither expedient nor wise to continue the publication of the names of members dropped for non-payment of dues; also that the last words, “for three years,” should be deleted.

Chap. 6, Arts. II, III and IV. We agree that these articles are in need of revision.

Chap. 7, Art. II. We do not agree with the suggestion that the Council, as now constituted, is too large to transact the ordinary routine business of this Association promptly. The business of this Association should be transacted by the Council, in the interval of the meetings, by the systematic presentation of motions, their discussion and the publication of the resulting vote in the "Bulletin."

Art. III. We agree with the recommendation that Section chairmen should not be members of the Council. The Section should, however, be represented in Council by a special delegate or vice chairman. We would therefore recommend that Art. III be made to read, “The President, Vice-President, General Secretary, Local Secretary, Treasurer, Reporter on Progress of Pharmacy, Editor of the 'Bulletin,' the Vice-Chairmen of the Sections of the Association and the Secretary of the Council shall be ex-officio members of the Council.”

A corresponding change should, of course, be made in the list of officers of the Sections so as to provide for one delegate to the Council or one vice-chairman of each Section to be elected annually.

Chap. 7, Art. VIII, should be revised as suggested.

The latter recommendation, however, that Local Branches should have the power to elect members, is not practical at this time.

Chap. 7, Art. VIII, Sec. 3. This is not impracticable, since it refers only to candidates to whom objection has been made.

Chap. 8, Art. I. This article needs no reconstruction.

Chap. 8, Art. III, has been recommended for revision in the report of this committee.

Chap. 9, Art. XIII, Sec. 7. The provision, as it now stands, can do no harm, and is an incentive for members to become interested in the Association.
Chap. 10, Art. 1. We agree with President Oldberg that it needs revision, as do the other articles of the chapter relating to the election of officers. There should be more uniformity in the number, duties and responsibilities of the officers of the several Sections. We do not concur in the suggestion that a committee of the A. Ph. A. should not propose programs of business to other Associations, and think it rather desirable that such a practice be continued and, if possible, be elaborated on so as to bring the work of this Association in correlation with the work of the several State and Local Associations.

E. G. Eberle,
M. I. Wilbert,
C. S. N. Hallberg, Chairman.

The report of the Committee on Reorganization,* read at the second general session and referred by the Association to the Council for consideration and action, was presented and discussed.

On motion of Mr. Caspari, seconded by Mr. Eliel, the reports were referred to a committee of five, to be appointed by the Chairman, to present in a concrete form, the proposed amendments to the constitution and by-laws, the committee to report at the next annual meeting of the Association.

Moved by Mr. Whelply, seconded by Mr. Caspari, and carried, that the consideration of the issuance of the A. Ph. A. Journal proposed by the Committee on "Bulletin," † and referred to the Council by the Association with power to act, be made the special order of business for Saturday, 8 a.m.

The report of the Committee on Unofficial Standards was made by Chairman Beringer, as follows:

REPORT OF THE COMMITTEE ON UNOFFICIAL STANDARDS.

The selection of this committee by the Council was only completed late in January, 1910, and in the short period intervening but little more than the preliminary outlining of the work could be accomplished. In addition to the voluminous personal correspondence between the members, six bulletins (copies accompany) have been issued, circulating to the members the views held on matters referred to the committee, the selection of articles to be standardized, and the preparation of tentative standards for some of these, and rules and regulations to be followed in the discharge of our duty.

A meeting of the committee has also been held at Richmond, and as a result of that conference our views have been crystallized along distinct lines of action.

RECIPE BOOK.

The question of the proposed recipe book referred to this committee has received consideration, and we are of the opinion that it is not expedient at this time to compile a recipe book.

It is the sense of the committee that for some time to come their efforts should be restricted to establishing correct standards for samples, and this voluminous undertaking will require all the activity of the committee.

More than fifty articles have already been selected by the committee for early consideration and standardizing, and assignments have been accepted for a number of these, and outlines for the proposed standards are being prepared.

The Committee on National Formulary has formally requested that this committee assist and cooperate in the preparation of standards for such drugs and chemicals as will be directed in the formulas, and for which there are no standards in the U. S. Pharma-

* See page 483.
† See report of the Committee on the "Bulletin," page 506.
SIXTH SESSION OF THE COUNCIL.

The importance and urgency of this work is so apparent that the Committee on Unofficial Standards have decided to give it immediate attention.

The committee have determined that their standards shall not be merely academic descriptions based on the text-books alone, but that in each case the referee shall be empowered to obtain information and assistance from all available sources, and that a number of pure commercial samples of the article shall be examined, and upon such information and determinations shall be based the definition, description and tests for identity and purity that will be fair, correct and proper for legal standards.

It is apparent that the work of this Committee will entail considerable expense, and that the members should not be compelled to bear this personally. It is, therefore, recommended that an initiatory appropriation of $150.00 be made by the Council for the purposes of this Committee, and that all bills properly approved by the chairman be paid therefrom in the usual course.

In the absence of pharmacopeial methods for determining the usual analytical data the Committee have agreed to adopt for such work the methods of the Association of Official Agricultural Chemists, as published in Bulletin 107, Bureau of Chemistry, Department of Agriculture.

The Committee have decided to make only one slight modification in the method of transacting the business, as published in the Proceedings of 1909, page 503, namely: that the vote on a motion be called for with the issuance of the bulletin containing the discussion on the motion, and that a majority of the votes cast shall be considered as sufficient for a decision.

The pressure of other business has compelled Mr. George B. Kauffman to ask to be relieved from the service. In presenting this resignation the Committee deem it advisable to direct the attention to the fact that the work assigned us is an arduous task, calling for continuous, intelligent and energetic application, and the composition of the Committee, therefore, should be comparatively permanent, and the complement should be completed at an early date. There is now special need for members who have devoted considerable attention to botany and pharmacognosy, and it is requested that in the filling of these vacancies this need be considered. The names of the following members are suggested as probably available for such appointments: William Mansfield, Edwin L. Newcomb, Albert Schneider and C. A. Dye. An early designation of the appointments and of the chairman for the year should be made, so that the work can be continued with little or no interruption.

The Council on Pharmacy and Chemistry of the American Medical Association has transmitted to your Committee the following resolutions:

WHEREAS, The American Pharmaceutical Association has appointed a standing committee to provide standards of identity and purity of unofficial drugs and chemicals, and

WHEREAS, This Council has for some time been engaged in the establishment of standards for those medicinal substances which, although unofficial, appear to possess some therapeutic value, and

WHEREAS, It is desirable that standards adopted by the Council and the Committee of the American Pharmaceutical Association should be in accord with each other as far as practicable.

Be it resolved, That the Council offer its cooperation to said Committee, and

Be it further resolved, That the said Committee be requested to examine and criticise the standards for unofficial non proprietary articles, so far adopted, and

Be it further resolved, That in the adoption of further standards for unofficial non-proprietary articles the available standards of said Committee be adopted, so far as practicable.

Your Committee is pleased to acknowledge this communication, and we appreciate the wish and the proffer of cooperation in the making of uniform standards, and have
reciprocated, and will cooperate in every way, and our outlines of proposed standards will be submitted for approval by the Council on Pharmacy and Chemistry, and their standards will be critically examined and adopted wherever possible.

Respectfully submitted,

THOS. P. COOK,      CHAS. E. VANDERKLEED,
L. F. KEBLER,       J. A. KOCH,
GEO. M. BERINGER,   W. A. PUCKNER,
H. KRAEMER,        O. RAUBENHIMMER,
E. H. LADISH,       M. I. WILBERT,
CHAS. H. LAWALL,    CHAS. E. CASPARI,
GEO. D. ROSENGARTEN,

On motion of Mr. Rusby, seconded by Mr. Meissner, the report was accepted and the recommendations adopted, except that the term “pure commercial,” used in the report, was changed to “pure.”

On motion of Mr. Rusby, seconded by Mr. Hallberg, it was decided to reimburse Mr. Beringer as Chairman of the Committee on Unofficial Standards $45 for cost of rotary mimeograph used for work of the Committee.

Mr. Whelpley moved, seconded by Mr. C. E. Caspari, that the action of the Association in prohibiting advertisements on programs and in meeting rooms be made a General Rule. Carried.

On motion of Mr. Whelpley, seconded by the General Secretary the action of the Association in turning over the records of the Association to the Historian was made a General Rule.

Mr. Whelpley moved, seconded by Mr. Hallberg, that D. M. Rand, of Portland, Me., be presented with a copy of the 1906-7 Proceedings on payment of dues to date. Carried.

Moved by Mr. Rusby, seconded by Mr. Hallberg, that the Association endorse the holding of the Panama Exposition in New Orleans in 1915. Carried.

ORGANIZATION OF COUNCIL OF 1910-1911.

The Council of 1910-11 was organized on May 6, 1910, at 11 a.m., Mr. Godbold acting as temporary Chairman.

The following officers were nominated and elected for the year 1910-11:
Chairman—James H. Beal.
Vice Chairman—Henry H. Rusby.
Secretary—J. W. England.

On motion duly seconded the following officers of the Association were elected for the year 1910-1911:

Treasurer—Henry M. Whelpley.
General Secretary—Charles Caspari, Jr.
Reporter on the Progress of Pharmacy—C. Lewis Diehl.
Honorary President—Ewen McIntyre.

Vice Chairman Rusby assumed the Chair, in the absence of the Chairman elect.

The following Committee on Finance was nominated and elected: J. A. Koch, J. P. Remington and E. H. LaPierre.

Mr. Meissner suggested that, hereafter, all bills, properly endorsed by the General Secretary, shall be sent by the Chairman of the Finance Committee directly to the Treasurer, instead of being returned to the General Secretary to be sent by him to the Treasurer, so as to expedite the payment of bills.

The following Auditing Committee was named: James M. Good, Otto F. Claus and Solomon Buehn.

The Committee on Transportation was elected as follows: C. S. N. Hallberg, Chair-
SECOND SESSION OF THE NEW COUNCIL. 517

Adjourned to meet Saturday, May 7, 1910, at 8 a. m.

Secretary England next read the minutes of the second session of the new Council of 1910-11, held on May 7th, 1910, as follows:

MINUTES OF THE SECOND SESSION OF THE NEW COUNCIL.

The second session of the Council was held May 7, 1910, at 8:30 a. m., Chairman Beal presiding. Present: Messrs. Beal, Hallberg, Rusby, Day, C. Caspari, Jr., C. E. Caspari, Apple, Asher, White, Whelpley, Koch, Johnson, LaPierre, Beringer, Diehl, Eberle, Lemberger and England.

The minutes of the previous meeting were read and approved.

The reports of the Committee on "Bulletin" were considered.

Recommendation No. 1, regarding the issuance of a monthly journal, was adopted, the first number to be issued July, 1911.

Recommendation No. 2, on the title of the journal (Journal of the American Pharmaceutical Association), was adopted.

Recommendation No. 3, on the scope of the Journal, evoked considerable discussion, and it was resolved that the editorialis be limited to synoptical references to the contents of the current Journal, and that on stated questions such expressions be confined to the attitude of the Association, if made at all, or if by special contributors, with their names or initials appended. It was resolved also that the Journal publish a note in each issue that the Association will not hold itself responsible for the expression of opinion of its contributors, and that personalities must be entirely eliminated.

It was decided also that original articles, and the Proceedings of the Association (Annual, Council and Branch), be published in the Journal, together with selections of original articles, including pharmaceutical abstracts, from other journals.

Recommendation No. 4, that only approved papers and advertisements be accepted for publication in the Journal, was adopted.

On motion it was agreed that the Journal be sent to members monthly, and that the Report on the Progress of Pharmacy be issued annually as a bound volume at the end of each fiscal year and sent to members also; both publications without charge. In addition those members who notify the General Secretary at the beginning of each year may receive a bound volume of both the Journal and the Report at the end of the year, upon the payment of a price to be fixed by the Committee on Publication. The price of $1 was suggested, but the exact amount was left to the discretion of the committee.

It was suggested that the editor of the Journal should prepare abstracts of domestic pharmaceutical journals, while the Reporter on the Progress of Pharmacy should confine his reviews to foreign pharmaceutical journals; and that the matter of the pharmaceutical abstracts of the Journal should be kept standing, after publication, so that it could be used also in connection with the foreign abstracts published in the Report at the end of the fiscal year. In this way the whole field of pharmaceutical literature could be reviewed in the annual Report at a minimum cost.

It was resolved the Report on the Progress of Pharmacy include the list of officers, prefatory matter, constitution and by-laws, general rules, roll of members, list of members, etc., of the previous proceedings; and it was decided also that the list of payments of membership dues now published in the Proceedings be not published in the new Report.

It was agreed that a standing Committee of nine members be elected annually by the Council to supervise the publications, to take the place of the former Committee on
"Bulletin" and Committee on Publication, this committee to be known as the Committee on Publication. The Committee was directed to prepare proper rules and regulations governing editing, publication and the censoring of advertisements.

It was suggested that the subscription price of the Journal to non-members be made $3 a year and the Report the same; but this was left to the discretion of the Committee on Publication.

On motion it was decided that the monthly "Bulletin," as now published, be continued until July, 1911, and that the average number of reading pages shall not exceed 48 pages per month.

C. S. N. Hallberg was elected editor-in-chief of the Journal, and Charles Caspari, Jr., and C. Lewis Diehl, associate editors.

C. Lewis Diehl, Reporter on the Progress of Pharmacy, was instructed to prepare a list of the assistant editors he desires for the Report, to report to the Council later.

It was decided that the editor and two associate editors with the Treasurer shall be ex-officio members of the Committee on Publication. The other members elected were: F. J. Wulling, Chairman; G. M. Beringer, M. I. Wilbert, F. W. Meissner and J. L. Lemberger.

Moved by C. Caspari, Jr. seconded by Mr. England, that the editor of the "Bulletin" and the Reporter on the Progress of Pharmacy of the Proceedings each receive an honorarium of two months' salary, due by reason of the overlapping of official and fiscal years.

Applicant for membership No. 216 was elected.

Mr. Rusby moved, seconded by Mr. England, that a Committee be appointed to formulate rules and by-laws for the creation of a class of members to be known as Sustaining Members. Carried.

Chairman Beal named the following as the Committee: H. H. Rusby, Chairman; W. B. Day and F. C. Godbold.

Moved by Mr. Rusby, seconded by Mr. Koch, that hereafter the retiring President of the Association shall become a member of the Council for a period of three years. Carried.

Chairman Beal suggested that an amendment be offered the Association covering the motion adopted.

The following amendment was offered by C. Caspari, Jr., and seconded by Mr. Hallberg:

Amend Rule 5 of General Rules of Finance by striking out everything after the words "shall be kept by him."

Amend Rule 9 by substituting the following for present rule: "Said books, accounts of vouchers, saving bank books and accounts of the same shall be returned to the Treasurer within two weeks of the date of their reception by the Chairman of the Auditing Committee."

Mr. Koch moved, seconded by Mr. Hallberg, that the Council appropriate a sum not exceeding $125 to cover the traveling expenses of the General Secretary and the Treasurer for this year. Carried.

The Chairman of the Committee on the Beringer Question presented the following resolution to the Council with recommendation for adoption:

"That the Council without endorsing the particular expression or precise language contained in the address of Mr. Beringer upon 'Why the Mann Bill Should Be Enacted,' read at the Atlantic City meeting of the American Pharmaceutical Association, hereby expresses its sense of appreciation of the fearless and able manner in which he championed the cause of American pharmacy by opposing the highly unjust and unfair provisions of our patent laws. And it is further the opinion of the Council that Mr. Beringer in his opposition of these laws was actuated by a sincere desire to better existing
conditions with respect to pharmacy, and not by any ulterior motives or by hope of personal profit."

The resolutions were adopted.

The members of the Committee on Unofficial Standards were elected as follows:
For one year: C. A. Dye (to succeed George B. Kauffman, resigned).
For four years: G. M. Beringer, Chairman; A. H. Rusby, C. E. Caspari and J. M. Francis.

On motion it was decided that the Committee on Membership of 1909–10 of the Council be reappointed for 1910–11, with the exception of Mr. Meissner (whose term as a Council member expires), and that Mr. Asher be named to succeed him; and also that C. Herbert Packard be named to succeed Mr. Eberle (who became the President of the Association).

J. W. England, Secretary.

The Chair stated that there was one feature of the minutes of the Council that it seemed to him it would be well to make a little clearer to the members, and that was the recommendation as to the change in the form of publication of the "Bulletin," which was very sweeping in its character. The proposition now was, to publish in place of the "Bulletin" a "Journal" of the American Pharmaceutical Association, to appear monthly, the pages of which were to be double the size of the present pages of the Proceedings. The members could either save these numbers as issued and have them bound at the end of the year, or not, as they chose. Those members who would give notice to the Secretary at the beginning of the year that they so desired would be entitled, on the payment of a small fee, at the end of the year to a bound volume of the issues of the "Journal," in addition to the copies that they received each month. The "Journal" would contain the various matters of interest to the members as heretofore appearing in the "Bulletin," such as the proceedings of the Association, news of the Branches, etc., and likewise all the papers that were presented before the Association. It would also contain abstracts, from month to month, of current events in pharmacy—something in the nature of the report of the Reporter on the Progress of Pharmacy, but not attempting to make it so complete in the "Journal." In the meanwhile, the Reporter on the Progress of Pharmacy would continue as before to make a complete report on the progress of pharmacy, to be published at the close of the year, the available abstracts as they appeared from month to month in the "Journal" to be kept in type and used at the end of the year, so that the report on the Progress of Pharmacy would be very much as at present, and would be bound separately, and a bound copy given to every member of the Association free of charge. Those members, however, who desired to obtain bound volumes of the "Journal," might, if they chose, have the report on the Progress of Pharmacy bound in with them. The report on the Progress of Pharmacy, properly speaking, would be a separate bound volume at the end of the year, and there would be included in that volume the Constitution, the By-Laws, the Index, List of Members, the prefatory matter now contained
in the Proceedings, and everything in the nature of material that must be referred to. The Chair thought this was a pretty clear statement of what the "Journal" would be, as far as he could give it in a moment or two. He suggested that possibly the newly elected editor might have something to add to this statement, to make the matter clearer to the members.

Mr. Ford, of Denver, objected to the idea of giving twelve months' advance notice to the Secretary that a bound volume would be wanted at the end of the year, and thought ninety days ought to be ample. It would not be desirable, anyway, to have a great number of extra volumes printed, when it was not known what would be called for to be bound, for this would be a great waste of material.

Mr. Payne, of Georgia, asked if the publication of the "Journal" was to take the place altogether of the publication of the Proceedings—whether the report on the Progress of Pharmacy was to be done away with altogether. The Chair stated that there would be a volume, not of Proceedings, but of all other matter which is now printed regularly every year; the Proceedings themselves would be published in the form of a "Journal," and members would not have to await their publication in book form. Then those who notified the Secretary in advance would get a bound copy of the issues of the "Journal" at the end of the year, and in that way they would get a complete bound copy of the Proceedings and everything together.

Mr. Hynson asked if any action had been taken in regard to advertising in the proposed "Journal." The Chair replied in the affirmative, and said there was to be a Committee of Publication, consisting of four ex officio members and five members who were to be elected—and whose names had been read—and they would have charge of advertising and everything else relating to propriety and policy, in carrying out the instructions of the Council as to the publication of the "Journal."

Mr. C. E. Caspari said he thought there was one point that might be emphasized, and that was, that if members elected to take a bound volume of the "Journal," with the report on the Progress of Pharmacy bound with it, at the end of the year, they would also receive, without any further cost, the "Journal" every month during the year, and they would really get two copies of the "Journal," one in the shape of the monthly issue and the other bound in with the report on the Progress of Pharmacy at the end of the year. That is, they would get the "Journal" as one of the privileges of membership, and the extra bound copy practically at cost.

Mr. Francis, of Detroit, suggested that the proposed change to a page twice the size of the present page would change the character of the entire collection of volumes that the members might already have. The Chair replied that the Council had taken all this into consideration, and it had previously been very carefully thought over by those who had been at
work upon this proposition in the past year; but the Council felt that the success of the "Journal" and the success of the Association would be increased by the fact of having a page of larger size.

Mr. Hallberg said it was an object-lesson to go to the shelves where the volumes of proceedings of the American Medical Association were standing in this form, and beside them see the bound volumes of the Journal of the American Medical Association. That it was right at this point where the American Medical Association "woke up" and became the great organization it is to-day. He said it would be found more convenient to the editors to have a larger page, and at the same time the cost was less than to publish the smaller page. So the Council, after thorough discussion, had concluded that the page should be made larger.

The Chair called for action upon the minutes of the Council as read, and on motion of Mr. Lemberger the minutes of the several sessions as read were approved.

At this point the Chair announced the appointment of Mr. J. O. Schlotterbeck, of Ann Arbor, Michigan, as a member of the Committee on U. S. Pharmacopoeia, in the place of George M. Beringer, resigned.

The Chair stated that he had been informed that the Section on Scientific papers had asked for the appointment of a Committee on Physiological tests—"a subject of which we are just beginning to learn the importance." He said he did not know whether he would be correct in appointing this Committee, but if any member of the Scientific Section was present, and would so inform him, he would proceed to appoint this committee.

Mr. Wilbert stated that the Section on Scientific Papers had passed a resolution requesting the Association in general session to provide for such a committee, and that the President be empowered to appoint a committee of five, to take into consideration the possibility of coordinating the various methods of standardizing drugs physiologically. He referred to the interesting program on physiological testing that the Section had had on Thursday afternoon, when this matter was threshed out, stating that it was the unanimous opinion of the members that while there was an apparent difference of ideas on this subject, the difference was more apparent than real, and that a committee of experts along this line could do much towards the establishment of standards satisfactory to all.

Mr. Dittmeyer, of West Virginia, moved the adoption of this resolution, and the motion prevailed.

The Chair called for reports of committees as the next business in order.
The following report of the Committee on Transportation was, on motion of the Secretary, read by title and referred for publication:

**REPORT OF COMMITTEE ON TRANSPORTATION.**

Your committee begs leave to report that on February 2d they applied to the joint passenger associations having authority to make rates asking for a special rate for the occasion of this meeting. Although the application was made thus early and was followed up by letters and telegrams, it was not until April 19 that the Trunk Line Association notified the committee that the roads on the Trunk Line territory would concur in the rate of one and three-fifths fares. Some of the railroads proved willing to circulate the members in their territory without cost to the committee, and in this way members were reminded of the meeting. Owing to the late date at which final action was taken by the Trunk Line and New England Associations the circulators of information were sent out later than they should have been. Your committee hopes to be able to secure even more advertising for the meetings in this way in the future than in the past.

The application of the two-cent law in some of the States, Virginia, for instance, makes the rate lower than the one and three-fifths fare now granted to conventions. In fact the concession granted is so slight as not to encourage the members to attend. Better rates can be obtained by traveling in parties of ten, but it is impracticable to travel in this way generally, as we rarely find so many who are willing to keep together throughout the entire trip.

The tourists' agencies offer somewhat better terms than the fare and three-fifths, but these offers are all based on travel on party tickets, which the members will not do except possibly where there is a long journey.

While the committee feel that we should obtain better rates, it seems no available means of influencing the decisions of the railway associations, whose actions are based on the numbers in actual attendance at a meeting. The suggestion of the President that some better rate should be made for members of the same family should be taken up and made the subject of negotiations by the incoming committee. For example, a rate of $29.60 from New Orleans to Baltimore and return will be in effect from May 7-11. This to the committee appears as showing a great deal of partiality, and ignoring the requests of this body. Your committee knows of several who have not attended this convention, but will attend the one in Washington next week. There is no doubt in the minds of this committee that were more conducive rates made, a much larger attendance at these conventions would be had, and the railroads in turn would derive a fuller benefit thereby.

The committee will be pleased to act on the suggestion of the President as to transferring its records to the incoming committee, and submits copies of correspondence with the railways.

If the Secretary of the Association would have some extra copies of the list of members struck off, and would furnish these to the several members of the committee, their efforts to obtain publicity through the distribution of circulars by the transportation companies would be aided materially.

*Caswell A. Mayo, Chairman, Philip Asher.*

The Secretary said that the report of the Committee on Organization of Local Branches was not very long, and might be read if desired.

The Chair said that this was an important report, and he thought it should be read. Mr. Mayo, Chairman of the Committee, presented the report as follows:
REPORT OF THE COMMITTEE ON ORGANIZATION OF BRANCHES.

Your Committee begs leave to report that while active efforts were put forth to effect the organization of a branch in one of the cities, where there seemed an opening for the organization of a branch, those efforts proved unavailing largely because of the existence of local conditions unknown to the committee.

There is a lesson for future committees in our experience. This lesson is that it is unwise for any one not on the ground and thoroughly familiar with local conditions to take the initiative in a move of this kind.

But we still have a field for usefulness for this committee in endeavoring to inspire local members to undertake the work of organization.

A branch has been established at Nashville, Tenn., mainly through the activity of J. O. Burge.

Respectfully submitted,

CASWELL A. MAYO, Chairman.

The Chair stated that without objection the report would be received, to take the usual course, and it was so ordered.

The Secretary called for the report of the Committee on National Formulary, and in that connection said he would like to present a special report of the Committee relative to a communication from the American Medical Association, which was referred to the Committee on National Formulary:

To the President and Members of the American Pharmaceutical Association:

After careful consideration of the communication from a Committee on National Formulary of the American Medical Association to this Association, which was referred to this Committee, we have the honor to report as follows:

The Committee on National Formulary of this Association are carrying on the revision of the work in accordance with the principles presented in their report at the annual meeting of 1908, at Hot Springs, Ark., and approved unanimously by the Association.

We are unanimously of the opinion that the cooperation of the medical profession is desirable if it can be secured upon the basis of the principles then adopted.

For the Committee on N. F., C. LEWIS DIEHL, Chairman.

Richmond, Va., May 7, 1910.

The Chair stated that before anything was done about this matter, he would like to say a word on the subject in behalf of the Association: "We do want cooperation with the medical profession," said the Chair, "but we want it to be cooperation. I think it is proper to say that if any set of persons comes to us claiming that they are ready to cooperate with us, but on condition they are to come in and tell us in advance what we are to do on all subjects, it certainly is not self respecting on our part to allow such suggestions to carry. I do not say that this is the attitude, but it seems as though there is a disposition on the part of the Council on Chemistry and Pharmacy to say to the Association: 'We will cooperate with you on condition that you will allow us to have our way in everything.' And this is simply a very respectful protest—not protest, but presentation of that Committee as to the views of this Association. We have been working on this line very practically; we have not worked
hastily, but carefully—practically, as well as scientifically; and we are glad to get coöperation: but it cannot be expected that the policy which has governed this Association, and which has been well considered by it, will be dropped or discontinued at a moment's notice, simply because we are invited to do so by somebody who is invited to coöperate with us. I think that is the meaning of that communication."

Mr. Diehl, of Louisville, referring to the communication just read, said he wished to say that there was present at this meeting nearly the entire Committee on National Formulary; that there was but a single member absent, Mr. Hall, of Detroit, who was unable to come. So that the communication from the Committee, as well as the report that he had to read, was the result of a conference practically of the entire Committee, and was practically unanimous.

Mr. Diehl then proceeded to read the following report:

REPORT OF THE COMMITTEE ON NATIONAL FORMULARY.

Less than a year having passed since the last report of the National Formulary Committee to the Association, we herewith present a statement covering that period.

If the present revision of the National Formulary simply demanded a correction of the formulas, the task of your committee might be considered so nearly completed that we could confidently look forward to the appearance in print of a revised edition before the expiration of the present year. It might be possible even to include acceptable formulas for new articles to be admitted into the "Formulary," if the conditions had remained the same as in previous editions. With the advent of the Food and Drugs Act of 1906, however, and the consequent recognition of the N. F. as a national standard under the provisions of this Act, it has become necessary, not alone to exercise the utmost care that the formulas shall be absolutely reliable, but also to introduce descriptions and standards for the ingredients required in the formulas for which none are now given in the U. S. P.

This embraces a long list of articles for which the descriptions necessary to establish their identity and purity must be provided, and it is impossible to estimate how much time will be necessary for this purpose. Moreover, formulas will have to be tried and confirmed for some seventy or more articles accepted by the committee for inclusion in the N. F., the alcohol percentages will have to be determined, in a large number of preparations, and the preparations themselves have to be made under the careful supervision of the committee, all of which will consume time that cannot at present be estimated.

NATIONAL FORMULARY BULLETIN.

One of the grave defects of the method of revision in effect until a few months ago has been the absence of a regular means of communication between the members of the committee. This has been overcome by the issuance of mimeograph "Bulletins." A number of these have been published during the last few months and have made it possible to reach conclusions by discussion and vote on many questions.

The committee would recommend that an appropriation be made for expenses in this connection, already incurred, and to provide means for the continuance of the "Bulletin."

PREPARATION OF SPECIMENS.

Definite action having now been taken upon practically all formulas voted to be retained in the N. F., and with the admissions well in hand, tentative conclusions having
been reached, the time has now come when specimens, in adequate quantity, should be prepared for the purpose of establishing uniformity and for the determination of such standards as may be required, such as alcoholic percent, etc.

The work of the Committee, up to this time, has been carried on, in so far as experimental work is concerned, practically without expense to the Association, through the generosity of the individual members.

The Committee now, however, recommends that there be placed at their disposal for carrying on experimental work, a sum not exceeding one thousand dollars ($1,000), to be expended under the direction of the General Chairman, in making a line of such preparations as may be found necessary; these preparations becoming the property of the Association, to be preserved and used as a basis of comparison in the work of future revisions.

CO-OPERATION.

It having become necessary, through the present legal status of the book, to establish standards and tests for those "simples" used in the preparations of the National Formulary, for which there are no standards in the U. S. Pharmacopoeia, an additional responsibility and a difficult task has been laid upon your Committee.

Inasmuch as the Association now has a Committee actively engaged in preparing such standards, lest there should be a duplication of work, and also that at time might be gained, your Committee has asked for and secured the co-operation of the Committee on Unofficial Standards to assist in the preparation of the standards and tests for those ingredients not described in the U. S. P., but used in the National Formulary.

GENERAL PRINCIPLES.

It may prove of interest to the Association to learn of certain general principles which are governing the present work of revision, these having been adopted by the Committee after thorough discussion.

A. The use of saccharin is to be discouraged and permitted in formulas only where absolutely necessary.

B. The revision is to be based upon the principles laid down in the prefaces of the original and revised editions; i.e., such articles as are largely called for by the physicians are to be admitted, therapeutic activity alone not to determine admission.

C. It is desirable to so construct the formulas that preparations may be made contemporaneously, providing the resulting product is satisfactory. With this purpose in view, fluidextracts may be used.

D. It is not considered wise to make any change in the composition or flavor of the preparations now in the N. F., other than to eliminate absolute faults and to conform to the requirements of the Food and Drugs Act.

E. The admission of four new, low-alcoholic-strength elixirs, is approved.

Compound elixir of cardamon.
Compound elixir of vanillin.
Compound elixir of a mold.
Compound elixir of glycyrrhiza.

F. No additional compound spirits of volatile oils are to be admitted. Those already approved are:

Compound spirit of cardamom.
Compound spirit of vanillin.

G. We approve of the lowering of the alcoholic strength of the saline elixirs, now in the N. F., providing there is no change in the flavor.

H. Cudbear and caramel are to be retained as coloring agents, and if feasible their solutions are to be standardized.

The final conclusions of the special committee on this subject have not been reported.
If, however, solutions of these substances, of definite tinctorial value, can be prepared, then these standard solutions may be used in the preparations without the use of color charts.

1. All formulas shall be as free as possible from compound preparations, becoming "independent formulas."

2. Part I of the N. F. shall contain all formulas, including those dismissed from former Pharmacopoeias.

The admission into the N. F. of preparations dismissed from the U. S. P. shall be determined in each case by the merits of the individual preparation.

3. Part II shall contain the descriptions and tests of the simples for which the N. F. provides standards.

4. "Introductory notes" to certain classes of preparations are not considered objectionable and are to be retained in a properly revised form.

5. Where standards, descriptions and tests are practicable for the "simples" and preparations of the N. F., they should be included.

STERILIZATION.

A chapter, outlining methods for sterilization as applied to pharmaceutical practice, is to be introduced in the N. F.

It is believed by your committee that future revisions of the National Formulary should be coincident with the revision of the Pharmacopoeia, but, to prevent the possibility of there being conflicting standards in the N. F. and U. S. P., we suggest the placing of a statement in the preface of the N. F. to the effect that if any of the standards adopted by the National Formulary are subsequently included in the Pharmacopoeia, the standards of that work shall take precedence over those of the National Formulary.

In closing this report we would ask for the support and co-operation of every member of the Association; with the increased responsibility which legislation has laid upon your committee, the labor has been more than doubled; however, the work is being actively advanced, and we trust will meet with your full approval when concluded.

Respectfully submitted on behalf of your committee,

C. Lewis Diehl, Chairman.

Richmond, Va., May 5, 1910.

The Chair stated that this was a very important report, and he knew there were members present interested in the subject presented. He invited discussion upon the report and the communication.

Mr. Wilbert said that as a member of the National Formulary Committee he desired to say that other duties had prevented his taking any part in the particular meeting referred to, and he wished to be regarded as dissenting from the answer to the American Medical Association. This was simply a personal feeling on his part, and he did not wish to impose his views on any one else.

Mr. Beringer said that there was a matter in the report that he desired to speak about. He said he thought that the pharmacists should continue to hold out the olive-branch to the medical profession. They want their cooperation, and need it, in the revision of the National Formulary. He thought the trouble was that the gentlemen who conferred with the Committee had an entirely different view-point from that which the practical pharmacist has to assume in his work, and it cannot be assumed that the work will meet the requirements of the pharmacologists who will use the
Formulary from that view point. But the Committee would certainly be only too glad to have the practical cooperation of the American Medical Association, and by no means would the Committee want the impression to go abroad that it had declined or did not desire the cooperation of that Association in its work.

Mr. Beringer then moved that the report of the Committee on National Formulary be adopted. The Chair called attention to the fact that the adoption of the report would carry with it an appropriation of $1,000.00 for the work of the Committee. The motion to adopt was seconded by Mr. Mayo and Mr. Eberle and carried.

The Chair called for report of the Committee on Status of Pharmacists in the public service of the United States as the next order of business, and Chairman Payne made the following report:

REPORT OF THE COMMITTEE ON THE STATUS OF PHARMACISTS IN THE PUBLIC SERVICE OF THE UNITED STATES.

Mr. President: The Committee on the Status of Pharmacists in the Public Service of the United States make the following report:

We have felt somewhat in a quandary as to how to proceed in our work the present year, in view of the adoption of the report of the Committee on the President's Address at the Los Angeles meeting last year. We believe that the committee itself misconstrued the President's words, and in the rush of business made a report which was intended to be innocuous, but which to some seemed to be "loaded for bear."

To leave everything relating to the status of pharmacists in the public service to the supposed benign and ever-watchful care of the various departments would seem to do away with any further opportunities for substantial work on the part of our committee, would permit matters to lapse back into the unfortunate conditions of the past, and would prevent our urging further needed substantial advancement.

If we cease all further efforts to secure a better standing as professional men in rank and in salary for pharmacists in the various public positions throughout the United States and devote ourselves only "to the elevation of their ability and work," we feel that our usefulness as a committee for advancing the status of pharmacists in the public service will be largely destroyed, and that to use our efforts only "to elevate the ability and work" of brother pharmacists holding public positions would not be conducive to improving their official status nor their appreciation and respect by the general public.

To gain some idea of how our Association felt as a whole on this matter, we wrote a letter to the members of the Association asking that they let us know whether in their opinion the work for the advancement of the rank and pay of pharmacists in the public service should be continued or discontinued. We have already received many hundred replies, and we most heartily thank the whole Association for the prompt, cordial and favorable manner in which it has almost unanimously expressed its desire that such work be continued.

Our work has been retarded by this peculiar condition of affairs. We have felt that the Association wanted us to do things which the report referred to seemed to disapprove, so we wish to be set clear, and offer the following resolution:

Be it Resolved, That in our desire to promote the professional advancement of all public and private pharmacists, we earnestly request of Congress and the Departments that proper commissioned rank and commensurate pay be accorded all pharmacists in the various branches of the public service of the United States.

Respectfully submitted,  
George F. Payne, Chairman.
The Chair suggested that those who would take the trouble to read carefully the words of ex-president Oldberg in his address of last year, would find that he did not object to an increase in the rank and pay of pharmacists in the government service, but that he did not think the proposition was confined to that, but spoke for a more thorough preparation of pharmacists.

Mr. Hallberg moved the adoption of the report and the accompanying resolutions, and spoke to his motion. He said he was one of those who, last year, had appended his name to the report of the Committee on President’s Address, and he confessed that since he had read that part of it more carefully and compared it with the President’s Address he felt that the reference in the report of the Committee might be construed to mean that the Association had receded from its long continued position on this question. He held that the Association had done splendid work in promoting the status of pharmacists in the public service, and had met with some degree of success, and he would be the last one to utter a word that could be taken as a reflection on the men in the service; and, since it was never too late to correct a mistake, he wanted to go on record as being in favor of this resolution.

Mr. Wilbert dissented from the resolution as presented by Mr. Payne. He thought that the Chairman, in sending out the inquiries referred to, must have selected persons not familiar with existing conditions, and he was not surprised that he should receive such answer from persons not well advised. He expressed the hope that the adoption of the Chairman’s motion would not carry with it an endorsement of the bill now before Congress—a bill which was objectionable to the surgeon general, since it was apparently in ended to hamper him, and which was, in his opinion, inimical to the service. He said if the Committee would take the time and trouble to inquire into the work that was being done by pharmacists at the present time, and inquire into the possibilities of the work that could be done by pharmacists by proper cooperation with the heads of the several departments, it would find that it might be pointed out to these heads of departments that a very much wider field of work could be outlined—a field in which they could be much more useful to themselves and the service; and he was sure that the Committee in doing this would be doing themselves justice and the Association a real service, to say nothing of improving the status of the men engaged in that branch of the service. One of the provisions in the bill now pending was, he said, that the men should be given commissions, and while this might seem a desirable thing, there was absolutely no advantage in it. He pointed out that there were other men now engaged in the public health work on the same plane with the pharmacists in this respect, and there was not a man in the service nor a scientist in the country, or anywhere, that did not respect and honor these men, because of the character of their work. He thought
the Association would be going entirely in the wrong direction by following the suggestion made in the report of the Committee.

Mr. Payne thought Mr. Wilbert was clearly out of order, because no reference was made in the proposed resolution as to any action to be taken upon any particular bill before Congress; and he never had, and would not, favor such legislation, unless he fully advised this Association in advance. What he had said about the two bills in Congress was entirely outside of his report, and simply an off-hand comment.

The Chair called on the Secretary to re-read the resolution offered by Chairman Payne in connection with the Committee's report, that the members might be fully informed, and he did so. Thereupon the Chair put the vote upon the adoption of the report and the accompanying resolution, and they were duly adopted.

The Special Committee on Editing Rules was here given an opportunity to report, and presented the following:

REPORT OF COMMITTEE ON EDITING RULES.

To the American Pharmaceutical Association:

Gentlemen: This Special Committee on Editing Rules, to which was referred the final recommendation of the President, and another item, respectfully offer the following resolutions, and move their adoption:

1. That the Secretary of the Association be, and hereby is, instructed to append to the names of members in our official directory their preferred title and academic degree.

2. That the publications of the Association be edited for form in conformity with editing rules to be adopted by the committee hereinafter provided.

3. That the committee comprise the workers responsible for the editing for form of the Bulletin, Proceedings, Formulary, Syllabus, and of such other publications, State or National, public or private, as may co-operate with this Association in a movement to secure greater uniformity.

4. That other Associations, State or National, be invited to nominate representatives in the formation of a general Editing Committee.

5. That the special committee be, and is hereby, instructed to bring this matter to the attention of the Pharmacopoeial Convention, to the American Medical Association and to the American Chemical Society at the earliest practicable moment.

6. That the suggestions made in the Section on Education and Legislation regarding the form or style of formulas be referred to the respective Committees on the Formulary and Pharmacopoeia.

Respectfully submitted,

J. P. Remington,
Henry L. Taylor,
C. S. N. Hallberg, Committee.

The Chair stated that the force of the recommendations of the committee was, first, that the proper titles should be appended to the names of members in the printed list of members. The rest of it, he said, although divided into five parts, amounted simply to this: that a committee is to be appointed for the purpose of conferring with similar committees, by other associations, to see if an agreement cannot be arrived at on this subject.
Mr. Mayo moved that the report be received and the recommendations be adopted, and this motion was duly seconded.

Mr. Mayo, in this connection, said he wanted to say a word in the nature of a correction that he thought should be made. Referring to that part of the President's Address dealing with the subject of titles, and the motive prompting the action of certain members of the Association some years ago when the rule was adopted abolishing the use of titles on the floor of the convention, Mr. Mayo said he happened to be present upon that occasion, when this rule was passed barring the use of titles on the floor and in the reports, and he knew that the reason assigned at the time for that action was that members did not know whether to address certain members as "Professor" or not. That it was not the use of the official title, but the use of the courtesy title, that was confusing, and it was the use of that title which was interdicted. Another, and the more potent reason for the adoption of the editing rules in question was, that the claim was made that this Association was composed wholly of professors, and it was considered advisable to disabuse the minds of the retail druggists of the country of any such impression. The desire was to make everybody feel that all were pharmacists here. He did not understand how the President could know what was in the minds of members who advocated the adoption of this rule to abolish titles. He did not think the statement made by the President was altogether correct, and he wished to make this explanation of how the rule was adopted.

The Chair said he was always ready to apologize for a mistake; but he also was present at the meeting in question, and he knew what was said at the meeting, and outside of the meeting. However, he would not press that matter, and was willing to withdraw this statement.

Mr. H. L. Taylor expressed the opinion that if the American Pharmaceutical Association could lead in a rational movement of this kind for the reform of the editing rules of this country, so that the American people might have some standard on this proposition, it would have accomplished a movement that had been in the air for a great many years. He did not believe the Association would ever have cause to regret having had the necessary energy to start a movement of such importance to the country.

Mr. Hallberg stated that he, also, was present when this matter of titles was considered by the Association, and he remembered the reason given for the adoption of the rule by Mr. Ebert at the time was, that when the average druggist of the country takes up a copy of the Proceedings, and looks over its pages and sees nothing but "Professor So and So," he will say to himself, "That Association is run by professors, and I don't want to have anything to do with it." For that reason Mr. Ebert moved to eliminate it from the proceedings, and the simple title of "Mister" be used instead. Mr. Hallberg said he thought this rule was a good one,
and ought to be retained, in the report of proceedings and in the discussions.

The Chair said there was no objection to that; that the question was simply upon the Directory of Members.

The Chair thereupon put the vote upon the adoption of the recommendations, and it carried.

The Chair appointed on the Committee on Editing Rules just provided the following:

The report of the Committee on Membership and Reception was called for, as the next order of business, and Mr. Day, Chairman of that Committee, made the following report:

REPORT OF THE GENERAL MEMBERSHIP COMMITTEE.

CHICAGO, April 30, 1910.

The Chairman of the Committee with the cooperation of the editor of the "Bulletin" began the campaign for members early in October in accordance with the instructions of the Council.

Considering the fairly uniform and faithful cooperation last year, the personnel of the Committee was but little changed and no time was lost, for the Committee was promptly appointed by the President.

The method of last year was followed except that the monthly letters were for the most part re-drawn in the endeavor to make them more attractive.

Four lists were obtained without much delay and a fifth list of one hundred from Texas was subsequently added, making a total of seven hundred and forty-two (742) names of eligibles. Besides these sixty members of Pharmacy Boards and two hundred officers of State Pharmaceutical Associations have received one or more letters and the "Bulletin" at regular intervals.

Of the four original lists containing about six hundred and forty names the first three have now expired: that is the last letter (No. 5) has been sent to them "inquiring why since they were recommended by Mr. —— they have not responded to our former letters," etc.

These lists have been returned to the senders informing them from whom applications have been received, and requesting them to make one final effort to secure their membership, and if desirable to revise the list and return it.

This appears to have had the desired effect, since many have felt compelled to write, who have not been heard from before, that "they appreciate the opportunity to join and may do so in the near future," etc.

The scheme came near being a failure toward the end of the year because instead of limiting the number of names to ten or twenty from each member, a number of lists with forty to fifty names were received, and as it was thought desirable, all these were added until the number was too large to be covered once per month as intended.

This was soon corrected, however, and some of the lists deferred until the first list of two hundred expired.

Unless the letters are received at least monthly the cumulative effect is lost and it is a question whether or not the letters should not be sent semi-monthly instead of monthly. It is strongly advised that this should be tried next year.
Of course one thousand names could be handled monthly by using duplication, but the postage and other expense would exceed the amount now appropriated, $60.00 per month.

Some experimentation has been conducted to determine the practicability of the employment of duplicate letters and the results with the Neosivte have been so successful as to recommend its use in the third and fourth letters. The fifth letter or last requiring insertion of the name of the recommending member, must always be individually written.

One-fourth of the time of the stenographer is devoted to the mailing list of the "Bulletin," which is inseparably connected with the membership work, since to every candidate is sent the "Bulletin," and when he becomes a member his name must be added to it. The time for the letter-writing may therefore be economized to afford the time necessary to the "Bulletin."

Noie.—It is most earnestly requested, however, that members of the committee limit the names sent in to the number asked for. Experience has amply demonstrated that from ten to twenty names can be handled by both parties concerned to the best advantage and bring the best results.

In exceptional instances a larger list may be used to advantage, as in Texas this year where the popularity of the President-elect brought splendid results, or where the Branch officers enter on a vigorous campaign for members, as Messrs. Beal, Koch, Saalbach, Blumenschein and Pritchard have done in Greater Pittsburg the past year, and Messrs. Burge and White in Nashville within the last few weeks.

The arguments advanced to the candidates for joining the Association have been varied from time to time without any appreciable difference in results, except that when the last letter is received many appear to be conscience-stricken, and either send in their applications or at least gladden our hearts with the information that they are actually considering "joining" us. This is the crux of such a campaign. If they can be made "to feel guilty" they are not hopeless and the committee feels encouraged.

EXPENDITURE.

The cost of the seven months' work exceeds slightly the sixty dollars per month appropriated, being $426.81 for seven months, or $6.81 in excess, a trifle less than one dollar per month.

Nearly one hundred names have passed through this office, representing five hundred dollars received. The receipts, therefore, barely exceed the expenditure, but it should be borne in mind that most of the work is preparatory to the meetings of the State Pharmaceutical Associations, which have not yet begun. These meetings commence in May (except Alabama and Arkansas; Louisiana having been postponed), and in June are in full force, continuing throughout July and August.

STATE ASSOCIATION MEETINGS.

It is at these meetings that the principal recruiting of new members must be had, and arrangements are being made for members of our committee to represent our Association, and with the help of our other members add to our membership.

It is believed a serious omission that the American Pharmaceutical Association has not always been represented at the State meetings, and that the principal duty of our President should be to appoint one of our members for such representation, and have him see to it that such delegate appear on the program of every State Pharmaceutical Association meeting right at the first session. This has been done by another Association, and the American Pharmaceutical Association certainly has equally good claims to attention when it is a question of what has been done for pharmacy and the pharmacists of the country.
Over two hundred new members have been elected by the Council, but there is no way of determining how many of these may be credited to the work of this committee. Nor is there information now at hand on how many of these Branches have received rebate of one dollar for each new member as decided by the Council. But even allowing rebate on fifty members, the balance would approximate fifty per cent. over the amount expended by this committee.

Efforts were made to secure a solicitor on the basis offered by Mr. J. H. Beal last year but so far without results, but the approaching summer months may afford opportunity to try the scheme.

The loss of membership from death has been unusually heavy the past year, many of our oldest members having passed away, among these P. C. Candidus of Mobile, Alabama and William Martin Nearby of San Francisco, California, members of this Committee who could always be relied on to get their share of members.

The resignations were numerous and probably inevitable for many reasons; but the losses through being dropped for non-payment of dues, while not as large as last year, were much too large—somewhat over one-hundred members. It is believed that this failure to pay the current dues promptly is largely owing to the provision that membership may be retained until the delinquent is three years in arrears. When a member owes as much as ten to fifteen dollars it is difficult to make him pay up and usually, he must be dropped from the roll.

STATEMENT OF EXPENSES OCTOBER, 1909, TO APRIL 30, 1910, INCLUSIVE.

Should the annual meeting in this populous center contribute its quota of members,
the prospects at the meetings of the State Pharmaceutical Associations should finally enable the Committee to reach the long-expected goal of five hundred new members.

With great appreciation to the members of the Committee, who have so zealously assisted in the work, shared equally with the Editor of the Bulletin.

I am faithfully,

For the General Committee on Membership,

W. B. DAY, Chairman.

The Chair called attention to the fact that there was a recommendation in the report that the President appoint a member of this Association for each State Association meeting, to represent this body, and called for action on this recommendation.

Mr. Mayo moved that the President be authorized and requested to appoint a member of this Association to represent it and cooperate with the Committee on Membership at each State Association meeting. This motion was duly seconded and carried.

Mr. Eberle called attention to the fact that the Section on Historical
Pharmacy had passed a resolution at its meeting this morning, requesting that a librarian be provided for that Section, and he wished to give notice of such action. The Chair asked if Mr. Eberle could give a little more specific information about this matter, and Mr. Eberle responded that this action was taken upon the recommendation of Mr. Kremers, Historian of the Section on Historical Pharmacy, who stated that the time had arrived when the publications and documents now in the hands of the Section should be placed in the charge of a librarian until such time as the Association should be provided with a library.

Mr. Mayo stated that his impression was, that it was a librarian of the Association, and not of the Historical Section, that was contemplated. His reason for thinking that was, on account of the reference books received and exchanged by the General Secretary of the Association, and he understood the reference to the Association to mean that the by-laws should be amended accordingly.

The Chair suggested that this matter be referred to the Council, to secure more exact information from the Section, and Mr. Eberle agreed to this. It was so ordered.

The Secretary stated that the report of the Committee on U. S. Pharmacopoeia had come to the Association in general session from the Section on Scientific Papers with a resolution to the effect that the set of general principles formulated be referred back to the general session, without recommendation.

The Chair stated that he believed the reason for this was that the Section felt that anything coming from the Association at this time would go to the Pharmacopoeial Convention direct, and not to the Committee on Revision, and it was more appropriate to come from the Association itself. He thought Mr. Beringer could give more exact information on this point.

Mr. Beringer stated that the situation was simply this: That when the report was presented to the scientific Section on yesterday evening, the various recommendations were read over and considered, and the rule was adopted that if no objection was offered to a particular recommendation it should be passed as approved. Some objection was made, and a question arose as to whether one or two of the recommendations should be adopted, and it was considered best to refer all these recommendations to the Association proper. It was thought highly desirable that the delegates from this Association should go before the Pharmacopoeial Convention with some definite statement of principles as to what was desirable in the forthcoming revision of the Pharmacopoeia, and he wanted to move now that the Association take up these various recommendations and pass on them, and when there was no objection made to consider that recommendation as adopted. Where there was objection the Association could amend or eliminate it. In this way the delegation to the Pharmacopoeial Convention would have some basis for its guidance at the convention.
This motion was seconded by Mr. Raubenheimer, of Brooklyn.

The Chair put the vote on the motion as made and it was adopted, and Mr. Beringer was called on to read the first recommendation, which he did, as follows:

1. Scope. The Pharmacopoeia shall be a book of standards for such substances as are sufficiently used as remedial agents to warrant recognition and the fixing of proper standards. We recommend that the limitations to the scope of the Pharmacopoeia adopted for the 8th Revision, and set forth in Article I (see Introduction U. S. P., VIII, p. XXX), be readopted for the next revision.

There was no objection to the recommendation as read, and it was passed as adopted.

Mr. Beringer read the second recommendation, as follows:

2. Function. The Pharmacopoeia is not to be considered as an authority on therapeutics, and the admission or deletion of any article is not to be considered as an indication of its medicinal value.

There was no objection to this recommendation, and it was declared by the Chair to be approved by the Association.

Mr. Beringer read the third recommendation:

3. Doses. That doses be continued in the Pharmacopoeia under the rule adopted for the 9th Revision, and that these be corrected wherever necessary, and that in addition, for potent remedies, the maximum single and the maximum daily dose also be given.

The Chair called on Mr. Raubenheimer to say what he thought of this proposition of a maximum dose. Mr. Raubenheimer replied that he had expressed his opinion on this the other day, and he thought this maximum dose should be followed by a distinctive mark; but that this could be easily arranged.

There being no objection, this recommendation was likewise passed as approved.

Mr. Beringer read the fourth recommendation:

4. Nomenclature. That the present rule relating to changes in titles (Introduction p. XXXI) be re-adopted with only such modifications as are necessary to comply with the subsequent suggestions.

There was no objection, and the recommendation was approved.

The fifth recommendation was read by Mr. Beringer:

5. Botanical Names. That changes in the present botanical names be made only for well-defined reasons and such changes shall conform to the rules of the International Botanical Congresses.

Mr. Hallberg asked how this would affect gambir. Mr. Beringer explained that this related to the botanical names of plants, not titles. This recommendation was likewise adopted.
Mr. Beringer read the sixth recommendation:

6. Names for Synthetic Chemicals. That for synthetic chemicals with lengthy chemical names, the committee coin wherever practical short euphonious titles contracted from the true chemical names and that the latter be always given as one of the English titles.

The Chair declared this recommendation adopted, as there was no objection.

The seventh recommendation was read by Mr. Beringer:

7. Purity Rubric. That the purity rubric as introduced in the eighth revision be continued and extended wherever practical and especially as related to crude drugs.

There was no objection to this recommendation, and it was declared adopted.

The eighth recommendation was read by Mr. Beringer:

8. Improved Descriptions and Definitions. That the official definitions and descriptions be carefully revised so as to meet the present need as legal standards.

The Chair stated that the substance of this recommendation has already been adopted in connection with a recommendation in the President's Address, and he assumed there would be no objection to this. It was declared adopted accordingly.

The ninth recommendation was read:

9. Committee on Drug Markets. That the Committee on revision be requested to appoint a special committee to make a thorough investigation of the quality of crude drugs in commerce both in this country and abroad, and to co-operate with the U. S. Government Departments in such investigations, and that this committee be instructed to endeavor to determine the proper limits to variability due to soil and climatic conditions or improper handling and to suggest such improvements as can be introduced in collecting and marketing such wares.

The Chair stated that he understood that this recommendation had been quite fully discussed in connection with this report, and seemed to be approved. It was declared adopted accordingly.

The tenth recommendation was read:

10. Standards for Crude Drugs. That reasonable and proper standards be introduced for crude drugs, wherever practicable, that will insure a satisfactory quality for the pharmacist and exclude substandard, fictitious or adulterated materials.

There was no objection, and the recommendation was adopted.

The eleventh recommendation was read:

11. Standards for Powdered Drugs. That titles and standards be introduced for such drugs as are properly used in the ground or pulverized condition and where the standards for the whole are not applicable to the powdered drug.
The Chair stated he thought perhaps this recommendation might be omitted, because almost exactly the same thing had been adopted in connection with the President’s Address, after discussion, and it would seem to be unnecessary to adopt it here. Mr. Beringer, however, said he thought it would be well to have it in concrete form, and Mr. Hallberg agreed with this view, as also Mr. Good, of St. Louis. The Chair thereupon declared the recommendation approved.

Mr. Beringer thereupon read the twelfth, thirteenth, fourteenth and fifteenth recommendations as follows, and there being no objection, they were declared duly approved:

12. Assay Processes. That the assay processes be extended to all drugs and preparations permitting of satisfactory testing in this way and that identity tests for the purity of the isolated active principle be included wherever possible.

13. Pharmacognostic Descriptions. That with the description of a crude drug, brief pharmacognostic descriptions both macroscopic and microscopic where possible be given and the appearance of the structural elements in the powder when examined microscopically as a means of detecting adulteration.

14. Methods of Storing and Preventing Deterioration. That instructions be incorporated for the proper storing of each article and methods of preventing deterioration.

15. Time Limit on Drugs. That a time limit of permissible use be fixed on each drug and preparation that is prone to deterioration or change of active constituents.

Mr. Beringer next read the sixteenth recommendation:

16. Fineness of Powders. That the designation of the fineness of powders be continued to be stated in terms of the number of meshes to a linear inch of a sieve through which the powder will pass, and that the diameter of the wire in the official sieve be fixed.

Mr. C. Caspari, Jr., suggested that it would seem that the concluding clause of the paragraph, “and that the diameter of the wire in the official sieve be fixed,” was unnecessary, as the present Pharmacopoeia directs the gauge of the wire to be used, and that would settle this matter. Mr. Payne, of Georgia, concurred in this view. Mr. Francis, of Detroit, thought it would do no harm to repeat this, and Mr. LaWall, of Philadelphia, concurred. Mr. Caspari did not insist upon the suggestion, and the Chair declared that the recommendation would stand approved as read.

Mr. Beringer read the seventeenth recommendation:

17. Powdered Drugs. The powdered drug to represent the entire drug. Where the drug can be powdered without residue this should be required; in other cases the allowable tailing or residue should be determined.

Mr. Raubenheimer said he was in favor of this recommendation, but that there were exceptions to the rule.

The Chair asked how it would do to insert the words, “unless specifically stated otherwise.” Mr. Beringer said he would consent to this. The Chair stated that with that change the section would be considered ap-
proved—with the words “unless specifically stated otherwise” inserted after the word “drug” in the second line. It was so ordered.

The eighteenth recommendation was read by Mr. Beringer:

18. Synonyms. That the proper English name under which the article is commonly sold be given, along with the Latin title, of each drug and preparation, and that a list of less important or less frequently used names be published with the other titles as a table of synonyms.

The Chair said he thought the Association should consider this recommendation carefully; that there was a good deal of difference of opinion between those who thought that synonyms should be put in a table to themselves and those who thought it would not be more convenient to give them in connection with the main titles, as is done in the Dispensatory. He thought it was a question that the Association should not pass upon without due thought, and perhaps regret its action afterwards.

Mr. Good, of St. Louis, could see no advantage in a table of synonyms if they were given under the proper heads—given after the name of the drug. He thought that was all that was necessary. The Chair replied that this was to have it in the Index, that was all. Mr. Good thought there was no objection to that.

Mr. Beringer was in favor of the recommendation as it stood, and the Chair said he presumed the committee had studied this matter out carefully, and if there was no objection the recommendation would be approved. It was so ordered.

The nineteenth recommendation was read:

19. General Processes. That type processes and general formulas be introduced wherever possible so as to prevent useless repetition in the text of formulas.

There was no objection, and the recommendation was approved.

The twentieth recommendation was read:

20. Description of Galenicals. That terse and concise descriptions of the official preparations be given after each formula.

The Chair invited an expression upon this recommendation, and Mr. Kraemer of Philadelphia and Mr. Ford, of Denver, said they thought it was all right. It was approved accordingly.

Mr. Beringer read the twenty-first, twenty-second and twenty-third recommendations as follows:

21. Sterilization. That a chapter on sterilization be introduced describing the proper methods for sterilizing medications and apparatus and indicating to what preparations each method is especially applicable.

22. Atomic Weights. That the current international standard of atomic weights be adopted for all official chemical formulas and calculations based thereon.

23. Structural Formulas. That structural formulas be not given in the revision of the U. S. P.
There was no objection to these recommendations, and they were approved as read.

Mr. Beringer read the twenty-fourth recommendation:

24. Discriminating Tests for the Druggist. That the simplest identification tests for the needs of the pharmacist be stated first in the list of tests and be in special type.

Mr. Wilbert stated that this was one of the paragraphs that was specifically objected to in the Section on Scientific Papers yesterday afternoon. It was pointed out that a distinction of this kind might lead to serious complications, as a distinctive type applied to one test might be construed as an indorsement of that test as distinguished from the others, thereby leading to complications in a legal way. He said the recommendation had been discussed at some length, and many of the members present objected to its wording, while others thought it might be eliminated altogether, without in any way impairing the force of the general statement of principles.

Mr. Mayo moved that the last five words, "and be in special type," be stricken from the paragraph, and Mr. Wilbert seconded this motion.

Mr. Richtmann, of Florida, said that this would disturb the entire system that had prevailed, and that that point was made in the discussion before the Section.

Mr. Beringer said if there was any doubt about this matter, he would be willing to let the entire paragraph go out, and Mr. Kraemer amended the motion of Mr. Mayo to that effect, that the Association eliminate this paragraph. The Chair stated that, without objection, this paragraph 24 would go out, and it was so ordered.

The twenty-fifth and twenty-sixth recommendations were read by Mr. Beringer:

25. Official Methods for Physical Constants and Chemical Determinations. That there be included official methods for determining the usual analytical data, such as specific gravity, melting and congealing points, ash, solubility, extractive, percentage of water, alcohol, ether, etc.

26. Normal Temperature. That an agreement be made between the Committee on Revision and the United States Bureau of Standards, by which a uniform official national normal or standard temperature shall be established for determining such constants as specific gravity and solubility, and at which apparatus should be certified.

No objection was made, and these recommendations were declared adopted.

Mr. Beringer read the twenty-seventh recommendation:

27. Definition of Admitted Impurity. That the character and composition of the innocuous impurities allowable in medicinal chemicals be stated with proper limitations and tests.

The Chair asked how this recommendation differed from the Purity
Rubric, and Mr. Beringer replied that the Purity Rubric might say 99 per cent. pure, but this would not say in what the impurities shall consist. No objection was made, and the recommendation was adopted.

The twenty-eighth recommendation was read:

28. Distinction between Medicinal and Technical Substance. That the statement relating to substances sold solely for medicinal purposes in the preface of the 8th Revision, page xxxix, be re-incorporated in the 9th Revision, and that the principle involved be stated clearly and more forcefully if possible.

The Chair stated that he understood this was one of the cases where there might be some proposition to remove it, and the committee wanted to forestall any such action by stating its views.

There was no objection, and the recommendation was adopted.

Mr. Beringer read the twenty-ninth recommendation:

29. Weights and Measures. That the metric system of weights and measures only be used in the descriptions and formulas.

There was no objection, and the recommendation was adopted.

Mr. Beringer read the thirtieth recommendation:

30. Alcohol Content. That with each formula for a preparation containing alcohol, the average alcoholic content of the product be given.

Mr. Wilbert stated that this was another of the paragraphs where there was considerable difference of opinion, and it was pointed out that this provision, if adopted in the Pharmacopoeia, might make a serious complication. The objection might be overcome by saying that the range of the alcoholic content should be stated—by making it "range" instead of "average." He believed the gentlemen who had pointed out this objection were not present, but thought in a general way this covered their objection.

Mr. Hallberg doubted the policy of incorporating all these details in a statement of principles, and thought that something should be left to the Committee of Revision. He asked whether the language employed, "the average alcohol content," meant the per cent. by volume of absolute alcohol.

Mr. Beringer said that the idea was that the percentage of alcohol should be stated within a range, so that the pharmacist in making a preparation might state the Pharmacopoeia requirement on his label, and save himself the necessity of determining the absolute alcoholic content of the mixture.

Mr. Wilbert suggested that if the pharmacist said the average content was 50, he would still have to make the determination. This would fix a standard, and then the pharmacist would be absolutely required to comply with that standard.
Mr. Francis said he was the man who raised the protest in the Scientific Section. He made the point on account of the retail pharmacist being subjected to this annoyance and expense. The Interstate Commerce label as to alcoholic preparations must bear the alcoholic content, but why should the local pharmacist burden himself to determine the alcoholic content in preparations made for local use? Why should he lay upon himself the unnecessary burden of having to assay his product to make his label good?

Mr. Beringer said he had no objection to striking this provision out of the recommendation, although he thought the gentleman who had last spoken was mistaken in his position.

Mr. Payne did not think well of the proposition to substitute "range" for "average," as, while it seemed a good way to settle this trouble, he was sure it would lead to trouble in the courts. His experience in Georgia had convinced him that this would be the result. Recently, he had had occasion to look into some fluidextracts, and he had found that they were running several per cent. in alcohol below the average, and he thought it was an unsafe thing to fix a range. It was hard to have a fast rule, but if the pharmacist does not have some definite standard, when he goes into the courts he is certain to have trouble.

Mr. Hallberg thought that the fault lay with the label printer. The label printer sells labels for Interstate Commerce, and one printer in Chicago will send labels all over the United States, with the exact alcoholic content printed on the labels. This was especially true as to a number of the Southern States—as Arkansas for example, where they had adopted the Federal Pure Food Law, which requires the alcoholic content to be stated. He said he thought it very important that the Association should take the right position in this matter, and he favored a declaration that for such and such purposes a range might be permitted in the alcoholic strength of five per cent. either way, below or above.

Mr. Ford said that in Colorado it was not required that the alcohol content should be stated; that the Federal law had been improved upon to that extent, and any article made according to the requirement of the Pharmacopoeia or National Formulary needed only to bear its official name, and the alcohol content was not required to be stated. Of course, if it was shipped into another State, it would come under the regulations of the Federal Pure Food and Drugs Law, and would have to have the content stated on the label. He thought this feature was one that could be carried throughout the entire book. He thought the pharmacist would not have to assay his preparations, if he observed carefully the official formula, kept the temperature uniform, and the bottle tightly corked, as the alcoholic content, unless decomposition set in, would remain uniform.

Mr. Clark, of Chicago, said that if it were practically possible to devise a working formula for the manufacture of tinctures or fluidextracts which
would yield, under different conditions, the same amount of alcohol each

MINUTES

time, it would be very desirable. Take fluidextract of belladonna, for in-

 SESSION.

stance; with that preparation made according to the official formula, 

under varying conditions of temperature, exposure and so on, the alcoholic

content will vary in an amount far exceeding any reasonable range that

could be placed on it in the Pharmacopoeia. The range of alcoholic

strength is very much more than five per cent. under varying conditions,

and if that strength is required to come within a certain range, the phar-

macist will be compelled to assay his product every time, to make certain

of its coming within the specified limits, and that would be an exceeding

hardship on him.

Mr. Stevens, of Ann Arbor, thought it absolutely essential that a range

should be stated, as, if a definite amount of alcohol content is stated on

the label, the pharmacist is necessarily compelled to assay the preparation

every time. He said that, as Mr. Francis had made clear yesterday, the

manufacturer in making a large amount of fluidextract or tincture, can

very easily assay it and put on the label the exact amount of alcohol it

contained; but if that requirement is made of the pharmacist, he will not

make his own preparation and assay it, but will buy from the manu-

facturer and not take the chance himself. Moreover, a difference in the

weather—the difference between dry and wet weather—and the character

and quality of the drug used, have a marked effect upon the product, and

for all these reasons it is desirable to have a range for the alcoholic con-

tent. Mr. Stevens also thought it might be well to add to this recom-

mendation, after the word "given," a clause to the effect that the product

be given in terms of per cent. by volume.

Mr. Raubenheimer thought that Mr. Beringer meant by this thirtieth

recommendation to show that the retail pharmacist could manufacture his

own preparations. What is wanted is an approximation, as it is im-

practicable for the pharmacist to state the exact percentage of alcohol.

Mr. Good, of St. Louis, said it was easy enough to calculate how much

alcohol is put into a preparation, but the proportion of alcohol in the fin-

ished preparation is a very different matter. He did not take to the

committee's suggestion to state the average amount of alcohol content,

and he doubted very much the feasibility of stating the range of alcohol

content. He had seen labels where the maximum amount of alcohol

content was stated.

Mr. Holzhauer could see no reason, aside from the legal requirement,

why the alcohol content should be stated when a preparation is made

according to a formula of the Pharmacopoeia.

Mr. Payne said that where the range of alcohol content was given in

pharmaceutical preparations, the courts had always decided that the

lowest percentage named was the one that was binding. He suggested

that the wording of the recommendation be changed to "calculated

alcohol content."
Mr. Hallberg said that, in his opinion, there would not be very much difference in the extractive proportion of the drug where the preparation is made according to the official formula, unless the druggist "went to sleep on his job" and left it standing around in an open vessel, and not tightly covered, for a day or two, when of course there would be an evaporation of the alcohol. He was satisfied that if the official formula was carefully followed there would be very little variation as to tinctures and fluidextracts. He thought that Mr. Clark was mistaken in thinking there would be such a wide range in result, where the article was made under the proper conditions.

The Chair suggested that the Association was consuming a good deal of valuable time on this question, which was not a vital one, as, even if no recommendation at all was made, the pharmacopœial convention would take care of the matter.

Mr. Payne called attention to the fact that he had moved to amend by inserting the word "calculated" in the place of "average" in the recommendation, but the Chair said this was not acceptable.

The Chair stated that the question now was upon the substitution of the word "range" for "average" in the recommendation, and said that Mr. Beringer had already agreed to that. A vote was thereupon taken upon the adoption of the recommendation as thus amended, and it carried.

Mr. Beringer read the 31st recommendation of the committee:

31. That wherever the Ninth Revision of the Pharmacopœia of the United States specifies a definite standard of strength or purity for any substance it shall also supply or contain an accurate and reliable method for the testing or assaying of said substance.

There was no objection to the recommendation, and it was declared adopted.

The Chair said a motion was now in order to adopt the recommendations submitted as a whole, and to request the delegates of this Association to the pharmacopœial convention to submit them to that convention. He said that in putting this vote he would like to call the attention of the members to the great amount of work that the committee had done in studying over each of these propositions before they had brought this statement of principles before the Association for action.

Mr. Clark asked if this provision referred to the Purity Rubric clause as well as the others.

Mr. Francis said that the motion made had no reference to the Purity Rubric; that it simply meant this: That if the Pharmacopœia mentioned a substance, and said that that substance must be of a definite character and strength, it must also provide a necessary and proper assay method for determining the purity of that particular substance, and not force a man to go to some work on chemistry to get an assay, or to get it out of his head or somewhere else.
The Chair stated that everybody having anything to do with assaying was objecting to the present Pharmacopoeia because of its failure to provide such assay methods.

Mr. Holzhauer said that as he understood the status of the recommendations now, it was that in Section 17, Powdered Drugs, after the word "drug," the first word in the second line, there should be inserted the words, "unless specially stated otherwise." that Section 24 had been eliminated, and Section 30 amended by substituting the word "range" for "average," before the words "alcohol content" in the second line. With this understanding, he moved the adoption of the recommendations as a whole.

Mr. Raubenheimer stated that at a symposium upon the subject of the Pharmacopoeias of the world, in the Section on Practical Pharmacy and Dispensing last night, Mr. Kraemer had called attention to the fact that the latest edition of the Dutch Pharmacopoeia contained a chapter on antidotes, and said it had been moved by Mr. Hallberg, duly seconded, that it be recommended that a chapter on antidotes be included in the Ninth Revision of the Pharmacopoeia. He offered this as an amendment to the motion of Mr. Holzhauer to adopt the recommendations as at present amended as a whole. This motion had a second in Mr. Ford and Mr. Hallberg.

Mr. Payne also heartily seconded this motion, as his experience had proven the desirability of such a chapter.

Mr. Holzhauer said he would be glad to accept the amendment to his motion. The Chair thereupon put the vote upon the motion of Mr. Raubenheimer to recommend the addition of a Chapter on antidotes in the Pharmacopoeia, and it carried.

The Chair then put the vote on the adoption of the entire list of recommendations as presented and amended, with instructions to the delegates from this Association to present the same to the Pharmacopoeial Convention as a statement of principles offered by this Association for guidance in the Ninth Revision of the Pharmacopoeia. The motion was carried unanimously.

The recommendations as a whole, thus amended and adopted, here follow:

GENERAL PRINCIPLES TO BE OBSERVED IN THE NINTH REVISION OF THE U. S. PHARMACOPEIA.

1. Scope.—The Pharmacopoeia shall be a book of standards for such substances as are sufficiently used as remedial agents to warrant recognition and the fixing of proper standards. We recommend that the limitations to the scope of the Pharmacopoeia adopted for the 8th Revision and set forth in article 1 (See Introduction U. S. P. VIII, p. XXX) be re-adopted for the next revision.

2. Function.—The Pharmacopoeia is not to be considered as an authority in therapeutics and the admission or deletion of any article is not to be considered as an indication of its medicinal value.
3. Doses.—That doses be continued in the Pharmacopoeia under the rule adopted for the 8th Revision and that these be corrected wherever necessary and that in addition for potent remedies the maximum single and the maximum daily dose also be given.

4. Nomenclature.—That the present rule relating to changes in titles (Introduction fol. XXXI) be re-adopted with only such modifications as are necessary to comply with the subsequent suggestions.

5. Botanical Names.—That changes in the present botanical names be made only for well-defined reasons and such changes shall conform to the rules of the International Botanical Congresses.

6. Names of Synthetic Chemicals.—That for synthetic chemicals with lengthy chemical names, the committee coin wherever practical short euphonious titles contracted from the true chemical names and that the latter be always given as one of the English titles.

7. Purity Rubric.—That the purity rubric as introduced in the eighth revision be continued and extended wherever practical and especially as related to crude drugs.

8. Improved Descriptions and Definitions.—That the official definitions and descriptions be carefully revised so as to meet the present need as legal standards.

9. Committee on Drug Markets.—That the Committee on revision be requested to appoint a special committee to make a thorough investigation of the quality of crude drugs in commerce both in this country and abroad, and to co-operate with the U. S. Government Departments in such investigations, and that this committee be instructed to endeavor to determine the proper limits to variability due to soil and climatic conditions or improper handling and to suggest such improvements as can be introduced in collecting and marketing such wares.

10. Standards for Crude Drugs.—That reasonable and proper standards be introduced for crude drugs, wherever practicable, that will insure a satisfactory quality for the pharmacist and exclude substandard, fictitious or adulterated materials.

11. Standards for Powdered Drugs.—That titles and standards be introduced for such drugs as are properly used in the ground or pulverized condition and where the standards for the whole are not applicable to the powdered drug.

12. Assay Processes.—That the assay processes be extended to all drugs and preparations permitting of satisfactory testing in this way and that identity tests for the purity of the isolated active principle be included wherever possible.

13. Pharmacognostic Descriptions.—That with the description of a crude drug, brief pharmacognostic descriptions, both macroscopic and microscopic, where possible, be given, and the appearance of the structural elements in the powder when examined microscopically as a means of detecting adulteration.

14. Methods of Storing and Preventing Deterioration.—That instructions be incorporated for the proper storing of each article and methods of preventing deterioration.

15. Time Limit on Drugs.—That a time limit of permissible use be fixed on each drug and preparation that is prone to deterioration or change of active constituents.

16. Fineness of Powders.—That the designation of the fineness of powders be continued to be stated in terms of the number of meshes to a linear inch of a sieve through which the powder will pass, and that the diameter of the wire in the official sieve be fixed.

17. Powdered Drugs.—The powdered drug to represent the entire drug, unless specifically stated otherwise. Where the drug can be powdered without residue this should be required; in other cases the allowable tailing or residue should be determined.

18. Synonyms.—That the proper English name under which the article is commonly sold be given along with the Latin title of each drug and preparation, and that a list of less important or less frequently used names be published with the other titles as a table of synonyms.
19. General Processes.—That type processes and general formulas be introduced wherever possible so as to prevent useless repetition in the text of formulas.

20. Description of Galenicals.—That terse and concise descriptions of the official preparations be given after each formula.

21. Sterilization.—That a chapter on sterilization be introduced, describing the proper methods for sterilizing medications and apparatus, and indicating to what preparations each method is especially applicable.

22. Atomic Weights.—That the Current International Standard of Atomic Weights be adopted for all official chemical formulas and calculations based thereon.

23. Structural Formulas.—That structural formulas be not given in the revision of the U. S. P.

24. Official Methods for Physical Constants and Chemical Determinations.—That there be included official methods for determining the usual analytical data, such as specific gravity, melting and congealing points, ash, solubility, extractive, percentage of water, alcohol, ether, etc.

25. Normal Temperature.—That an agreement be made between the Committee on Revision and the United States Bureau of Standards, by which a uniform official national normal or standard temperature shall be established for determining such constants as specific gravity and solubility, and at which apparatus should be certified.

26. Definition of Admitted Impurities.—That the character and composition of the innocuous impurities allowable in medicinal chemicals be stated with proper limitations and tests.

27. Distinction between Medicinal and Technical Substances.—That the statement relating to substances sold solely for medicinal purposes in the preface of the 8th Revision page xxxix be re-incorporated in the 9th revision and that the principle involved be stated clearly and more forcefully if possible.

28. Weights and Measures.—That the metric system of weights and measures only be used in the descriptions and formulas.

29. Alcohol Content.—That with each formula for a preparation containing alcohol, the range of alcohol content of the product be given.

30. That wherever the Ninth Revision of the Pharmacopoeia of the United States specifies a definite standard of strength or purity for any substance it shall also supply or contain an accurate and reliable method for the testing or assaying of said substance.

31. Antidotes.—That a chapter on antidotes be introduced.

Mr. Beringer called attention to the fact that there was still another recommendation in the report of the Committee on U. S. Pharmacopoeia which should be decided by this Association—the recommendation that the delegates should present to the Convention a copy of last year's report, as well as this year's report.

This motion was seconded by Mr. Hallberg and carried.

Mr. Whelpley moved that the Association direct the General Secretary to address to the Surgeon-General of the Public Health and Marine Hospital Service a letter expressing the appreciation of this Association of the services that department had rendered in co-operating with this organization in the work of the Committee on U. S. Pharmacopoeia and National Formulary. This motion was seconded by Mr. Holzhauer and others, and was carried.

The Secretary said that he had a number of short communications that
he feared might be overlooked, and he would like to present them at this time. He read the following telegram from Little Rock, Arkansas:

**Little Rock, Ark., May 5, 1910.**

Chas. Caspari, Jr., Sec'y. Care Hotel Jefferson, Richmond, Va.

Remembrance of my brethren touches me deeply. My disappointment was great, am improving.

John B. Bond, Sr.

The Secretary then read the following resolution coming from the Section on Scientific Papers:

Resolved, That the Scientific Section of the American Pharmaceutical Association request the Association in general meeting assembled to endorse their request that the U. S. P. convention direct the Committee of Revision to submit the proposed changes in the U. S. P. to the members of the A. Ph. A. for review before final adoption for inclusion in the U. S. P.

On motion of Mr. Beringer the resolution just read was adopted.

The Secretary read a second resolution coming from the Scientific Section as follows:

On motion of Mr. Sollman, seconded by Mr. Whelpley, resolved that the Section on Scientific Papers favors the recommendation by the American Pharmaceutical Association of the physiological standardization of drugs to the serious consideration of the United States Pharmacopœial Convention.

Mr. Wilbert moved the adoption of this resolution, and the motion prevailed.

After the resolution had been adopted, Mr. Raubenheimer remarked that he desired to be considered not only a scientific, but a practical pharmacist, and he wanted the Pharmacopœia to be a practical book, so the average pharmacist could follow its directions, and he could not follow it if this method of standardization was adopted.

The Secretary read a third resolution emanating from the Scientific Section, as follows:

On motion of Mr. Hallberg, seconded by Mr. Selzer, resolved that the Section on Scientific Papers request the American Pharmaceutical Association to recommend that the Internal Revenue Department permit the use of such forms of distillers' package for alcohol for medicinal use as will obviate the objections to the present common barrel package.

Mr. Francis said that as he understood the force of this resolution, it was to permit the use of metal instead of wooden containers. Mr. Wilbert said that this was correct.

Mr. Hallberg thereupon moved the adoption of the resolution as presented, and the motion was duly seconded and carried.

The Secretary said that the Chairman of the Committee on Patents and Trade Marks was not present, but he had the report of the committee, a
typewritten document of considerable size. The Chair said he felt it
would not be feasible to go into this report at length, unless the Associa-
tion was ready to stay here all night.

Thereupon Mr. Wilbert, seconded by Mr. Ford, moved that the report
be received, to take the usual course, and the motion prevailed. The re-
port is as follows:

REPORT OF THE COMMITTEE ON PATENTS AND TRADE-MARKS.

The report of your Committee presented at the last annual meeting has been before
the Association for one year, yet, although it deals with a subject vital in its importance
to medical and pharmaceutical practice and to the public health, it has excited but little
discussion. This is doubtless due to want of knowledge regarding the principles under-
lying the practice of medicine and pharmacy and the object of the patent and trad-
emark laws in their relation thereto.

I. THE PROFESSIONAL PRACTICE OF MEDICINE AND PHARMACY.

But we must consider at the outset the fact that when a person enters one of the so-
called liberal professions, namely, theology, law, or medicine, he takes upon himself the
obligation to donate to his profession for common use the results of his observations and
experience, and he is therefore forbidden to patent his inventions and discoveries.

The following by-law was recently presented to the members of the Philadelphia
County Medical Society, and adopted at the business meeting April 20, 1910:

"Any physician who shall procure a patent for a remedy or for an instrument of
surgery, or who sells or is interested in the sale of patented remedies or nostrums, or who
shall give a certificate in favor of a patented or proprietary remedy or patented instru-
ment, or who shall enter into an agreement to receive pecuniary compensation or patron-
age for sending prescriptions to any apothecary, shall be disqualified from becoming a
member; or if already a member, upon conviction of such offense in accordance with
Art. VIII, he shall be ipso facto deprived of membership."

The arts of pharmacy and therapeutics are co-related and mutually dependent. The

- text-books and pharmacopoeias are dependent upon the professional work of both phar-
macists and physicians. Both are under the same obligations to science; both are bound
to contribute the results of their observations and experience to the profession. But the
pharmacist and manufacturer engaged in the practice of the pharmacologic arts deal
with material substances and are dependent upon materia medica commerce for a living.
This commerce requires the use of capital and its protection by legitimate commercial
methods, including the legitimate use of patents and trade-marks. In spite of the fact
that physicians are forbidden to patent their inventions or to derive an income from the
sale of "patented or proprietary" medicines, it is considered perfectly ethical for physi-
cians to copyright their books and to share with publishing houses in the profits derived
from their sale. Why should there be an exception made against patented medicines?
One of the reasons is that the patent and trade-mark system is used by the nostrum
trade to protect and foster a commercial business conducted in opposition to legitimate
medical and pharmacal practice by persons who are practicing medicine at wholesale
and without diagnosis, to the great detriment of the public welfare.

II. THE PATENT SYSTEM.

The object of the patent law is to promote progress in science and the useful arts.
We will therefore assume that when it is properly applied to medicine and pharmacy it
is capable of promoting progress in medical science and arts.

The object of the patent law is not to protect inventors except as a means to an end.
Inventors do not possess a natural right to the exclusive use of their inventions. The exclusive right to the use of an invention, when such right exists at all, is a creature of statute and of grant, and subject to the conditions imposed by the statute and by the grant.

The exclusive right to practice medicine and pharmacy has already been granted to the medical and pharmaceutical professions respectively; therefore the government should not grant to materia medica inventors rights which conflict with the license to practice medicine and pharmacy.

The medical arts, including pharmacy, have as their primary object the prevention and cure of disease. Drugs to be of real service for this purpose must be employed in accordance with certain principles known and appreciated only by persons who possess a comprehensive medical and pharmaceutical education.

This fact is recognized in the medical and pharmacal laws, the principal aim of which is to ensure that no one who has not proved his possession of both theoretical and practical education shall practice the profession of medicine and pharmacy.

Unless the patent law is so applied as to promote progress in Materia Medica science and in the arts of pharmacy and pharmacotherapy, upon which that science is dependent, the object of the patent law is defeated. And, as these arts are so related and mutually dependent, the proper application of the patent law cannot be accomplished except under proper medical and pharmacal laws and codes of ethical rules jointly devised and adopted by the medical and pharmaceutical professions.

The primary object of the patent laws is often lost sight of when the subject of patent laws and their application to medical science and arts is discussed in professional and commercial circles and in the halls of State Legislatures and of Congress. The impression naturally derived from the character of the discussion is that the primary object of the patent law is to protect inventors in creating and maintaining everlasting monopoly of their invention, not the promoting of exact knowledge regarding inventions in order that science may be advanced and the public benefited by having the right to the free use of the inventions when the seventeen-year lives of their patents expire.

The Committee suggests as subjects of discussion:

1. Is it advisable for the United States Government to grant inventors of new Materia Medica products the right to their exclusive manufacture and sale, when such inventors employ commercial methods not in harmony with the professional practice of medicine and pharmacy? Or is it better policy for the government to revoke all such grants and to place the introduction of new Materia Medica products under professional control?

   "a. There is a great difference in the character of the demand for Materia Medica products resulting from their proper use in medical and pharmacal practice, and the demand created by the misleading advertisements of certain commercial manufacturing houses engaged in the chemical and pharmacal industries. The former may be properly termed a natural demand, the result of the practice of medicine and pharmacy by qualified practitioners; the latter an artificial and fictitious demand, the result of ignorance and greed."

   "b. The professions of medicine and pharmacy have a right to demand censorship and control over Materia Medica commerce, provided the professions themselves are conducted in a professional manner to promote progress in Materia Medica science and the useful arts of pharmacy and therapeutics; they have a right to demand that no grant shall be given to individuals, firms, or corporations not in harmony with the proper practice of medicine and pharmacy; they have a right to ask the government to revoke all patent grants not practiced in harmony with the altruistic principles upon which medicine and pharmacy are founded; and the government not only has the right to revoke such grants but is in duty bound to do so in defense of the public welfare."

2. Progress in pharmacy and therapeutics is dependent upon the impartial discussion
of Materia Medica products in the medical and pharmaceutical journals. Is it possible to obtain such discussion under a system of materia medica monopoly, in which new products are controlled by product patents, and physicians and pharmacists are threatened with reprisal by the monopolists if their expressions regarding such products are unfavorable?

3. Progress in Materia Medica science and arts is likewise dependent upon the standardization of Materia Medica products, and the codifying of such standards in the United States Pharmacopoeia and the National Formulary. Are such standardization and codification hindered or promoted when Materia Medica products are subjected to commercial monopoly and are introduced by misleading advertisements?

4. The patenting of materia medica products is considered inimical to public interests in nearly every civilized country in the world, even if Russia; yet such patents are allowed in the United States of America. In most foreign countries patents are allowed for processes and machinery for manufacture. Should the granting of product patents by the United States Government be abolished and process patents be allowed? If process patents only are allowed the law should be modified to make it truly protective.

5. Is it wise public policy for the United States government to grant to foreign inventors patents by which they are enabled to build up industries in foreign lands at the expense of this country, or should the granting of patents be limited to inventions manufactured in the United States?

III. THE TRADEMARK QUESTION.

The function of the trademark is to indicate the ownership or origin of the brand, not the ownership of the product. There can be no ownership of a product of such nature as to prevent others who possess the necessary knowledge from making and selling the same product under its proper or descriptive name, unless such product is patented. It is axiomatic that "no one can claim protection for the exclusive use of a trademark or trade name which would practically give him a monopoly in the sale of goods other than those produced or made by himself. If he could, the public would be injured rather than protected, for competition would be destroyed. Nor can a generic name, or name merely descriptive of an article of trade, of its qualities, ingredients or characteristics, be employed as a trademark, and the exclusive use of it be entitled to protection." *

"When an article is made that was theretofore unknown, it must be christened with a name by which it can be recognized and dealt in, and the name thus given it becomes public property, and all who deal in the article have a right to designate it by the name by which alone it is recognizable." †

Before there can be a brand there must be a product with a name and identity of its own. Linen is a product. "York Mills" linen is the name of a brand. Condensed milk is a product. The word "Eagle" is used to designate the brand of a well-known manufacturer of this product. The office of a trademark is to point out the manufacturer of a brand. The words "York Mills" and "Eagle" are used by the manufacturers as pseudonyms, noms de plume, or commercial signatures, in place of the names of the manufacturers. When purchasers ask for "York Mills" linen and the merchant substitutes some other brand, without the consent of the purchaser, a fraud has been committed. This is fraudulent substitution.

Of late years the nostrum manufacturers have devised a system by which they are attempting to create and maintain monopolies upon unpatented materia medica products, by registering as trademarks the names which they have given to their products, and by prosecuting those who supply these products under these names unless the original brands are dispensed. It is manifest from the foregoing that this is unjust.

* Canal Co. vs. Clark, 13 Wall, p. 323.
It is believed by many that when a person registers a name as a trademark he has been granted by the government the exclusive right to the use of such name. This is an error. No right is gained by registering a name as a trademark which gives the manufacturer the privilege of using the name except as a mark to distinguish his brand from other brands of the same article. There is no such thing as the ownership of a name per se.

Others believe that they can obtain the exclusive ownership of a name by copyrighting it. This is also an error. As stated in Circular No. 19, issued by the Librarian of Congress, Washington, D. C., "The copyright laws contain no provisions under which protection can be obtained upon a mere name or title. Entry cannot therefore be made in the Copyright Office for coined names, names of articles of manufacture, names of games or puzzles, names of substances, names of products or names of medicines."

The decision of the United States Supreme Court in the Singer Sewing Machine case brings out very clearly the principle of trademarks. This decision is as follows:

"The result, then, of the American, the English and the French doctrine universally upheld is this, that where, during the life of a monopoly created by a patent, a name, whether it be arbitrary or be that of the inventor, has become, by his consent, either expressed or tacit, the identifying and generic name of the thing patented, this name passes to the public with the cessation of the monopoly which the patent created. Where another avails himself of this public dedication to make the machine and use the generic designation, he can do so in all forms, with the fullest liberty, by affixing such name to the machines, by referring to it in advertisements, and by other means, subject, however, to the condition that the name must be so used as not to deprive others of their rights or to deceive the public, and therefore that the name must be accompanied with such indications that the thing manufactured is the work of the one making it as will unmistakably inform the public of that fact."

It is evident from this decision, and other evidence before furnished, that certain manufacturing houses are attempting to deprive the retail druggists of this country of their rights. The American Pharmaceutical Association should protest against this attempt. To make their protest effective, the subject should be presented to the medical profession in such a clear light that physicians can have no excuse in the matter. When a physician writes a name on his prescription he should know whether or not he means to specify a brand. The pharmacist who dispenses the product should also know what is intended. When the intent of the physician is to specify a brand, the pharmacist who without his consent dispenses another brand is guilty of fraudulent substitution and merits fine and imprisonment.

It has been suggested that a Committee on Nomenclature be appointed by the American Medical Association and the American Pharmaceutical Association, jointly, the duty of which shall be to investigate the status of each new materia medica product and to place the knowledge thus derived before the professions, either in the form of a special report or in the pages of the medical and pharmaceutical journals, so that the physicians when prescribing may be guided in relation to the names and the claims regarding them made by the manufacturers of the products.

This suggestion is worth considering, and the committee presents it for discussion.

RESOLUTION.

WHEREAS, The object of the patent law is to promote progress in science and useful arts; and

WHEREAS, Progress in the science of materia medica and in the arts of pharmacology and therapeutics, upon which it is dependent, requires that each materia medica product and preparation shall have a name of its own, which is free to science and commerce, whereby it may be identified, impartially discussed in the professional societies and press, and thus prepared for a place in the U. S. Pharmacopoeia; and
Whereas, The practitioners of the pharmacologic arts, namely, pharmacists, chemists and manufacturers, are dependent upon materia medica commerce for a livelihood; and

Whereas, Commerce in materia medica requires the investment of capital and the protection of the same by the legitimate use of patents for new materia medica inventions, and trademarks for distinguishing between brands; therefore be it

Resolved, That the Report on Patents and Trademarks of the American Pharmaceutical Association, together with papers and discussions dealing in an explanatory way with the same subject, be referred to the manufacturing houses, with the request that they shall co-operate with the American Pharmaceutical Association in solving the several important problems presented by said report, and that the Committee on Patents and Trademarks be empowered to take such action and report the results of the conference at the next meeting of the American Pharmaceutical Association.

THOS. V. WOOTEN,
FRANKLIN M. APPLE,
F. W. MEISSNER,
F. E. STEWART, Chairman.

In the absence of Chairman Motter, of the Committee on Pharmaceutical Collection at Washington, the Secretary gave a brief abstract of the report, the full text thereof being as follows:

April 1, 1910.

To the President American Pharmaceutical Association:

Dear Sir: I beg to invite your attention to the following letter:

SMITHSONIAN INSTITUTION,
UNITED STATES NATIONAL MUSEUM,
WASHINGTON, D. C., March 26, 1910.

DEAR DR. MOTTER: Replying to your letter of the seventeenth instant, I regret to say that it has not been possible, up to the present time, to give definite consideration to the subject of the proposed pharmaceutical collection in the National Museum, and there will be some further delay in the matter. This condition is largely due to the delays in completing the new building, which has retarded the re-arrangement of the existing collections much longer than was expected. I assure you, however, that the matter has not been lost sight of, and the correspondence is now together on my desk. Should you desire and find it convenient to call at the Museum, I shall be very glad to explain the circumstances more in detail.

Very truly yours,

(Signed) R. RATHEUN,
Assistant Secretary, in charge of National Museum.

There has been no other business in this connection requiring the attention of your committee. The committee can, therefore, only report progress. In a personal interview, Mr. Rathbun assured me of his continued and favorable interest in the general proposition, and he regrets that, under existing conditions, more rapid progress is impossible.

Respectfully submitted,

MURRAY GALT MOTTER,
Chairman Committee on Proposed Pharmaceutical Collection at Washington.

The Chair explained the trouble about changing from the old to the new building in Washington, and said that the general tendency of the authorities of the museum was in the direction of liberality in such matters; that he had talked with them several times.

Mr. Wilbert stated that the new building was already overcrowded, and
the future in that direction did not give promise of a better condition. As a hope for the future, he outlined the prospects of the erection of a "George Washington Memorial Building," concerning which there was considerable sentiment in Washington City and in the country at large, in which it was proposed to house national associations of various kinds, and particularly scientific organizations. In this building would be room for library purposes, offices and a large convention hall, with smaller rooms for section meetings. The building as proposed would cost over $2,000,000, and the proposition was to endow it so as to make it self-sustaining. A number of national associations were taking an interest in this movement, and he thought it would be wise if this Association would consider the advisability of cooperating with the promoters of this movement to the end of a possible development in the city of Washington of a headquarters for the Association. This Association is distinctly a District of Columbia organization, chartered under the laws of the District, and he thought it eminently fitting that it should have some affiliation with the capital of the country. He said he would like to see a committee appointed to inquire into the practicability of cooperating in an active way with the promoters of this George Washington memorial building movement, so as to participate in the possible benefits that might come from the erection of such a building. The idea as outlined at length was a most interesting one, and he thought it offered this Association an opportunity in the city of Washington.

Mr. Whelpley moved that Mr. Wilbert be made a committee of one to inquire into the possibilities of this George Washington memorial building proposition, and Mr. Hallberg seconded the motion, and suggested the raising of the necessary money through the sale of appropriate buttons at $1 each. He thought this idea might be very attractive to members, and result in a substantial sum, and that such a good impression might be made as to induce those having the matter in hand to provide a hall and ample space for the Association.

Mr. Wilbert asked Mr. Whelpley when the proposed committee was to report, and Mr. Whelpley replied at the next annual meeting.

Thereupon the Chair put the vote upon the motion as proposed by Mr. Whelpley, and it was adopted, and the Chair announced the appointment of Mr. Wilbert upon this committee of one.

Mr. Whelpley said that this reference to the city of Washington reminded him of a letter that he had received, which he thought would be of interest to the Association, from ex-treasurer Sheppard, who had asked him to extend to the members present his greetings. In this letter he had inquired about the progress of the General Endowment Fund of the Association, concerning which Mr. Whelpley made the statement that this fund now exceeded the sum of $5,000, but must reach the sum of $25,000 before the Association could make use of the interest upon it, the interest
then being available only for general expenses, and not for any special purpose, such as the matter in hand. This $5,000 had been practically contributed by three men. He said Mr. Sheppard had requested him to lay special stress upon the fact that contributions of from one dollar up would be acceptable, and he expressed the hope that before the members left for their homes he should be able to add a number of one-dollar contributions to the fund.

The next report called for was that of the Committee on Wm. Procter, Jr., Monument Fund, and Chairman Hancock made a verbal report showing progress. He said that for the last two years very little had been done; that there was in the treasury of this fund at the present time the sum of $3,666.83, and that pledges received would run this up to something over $4,000. Mr. Hancock then went at length into a statement of the prospects of the fund and the various means and devices, such as working through the State Associations, the sale of Procter buttons, etc., by which it was hoped to raise the desired amount in the next few years, so that the monument in contemplation might be erected and unveiled at least by the year 1917, the 100th anniversary of the birth of Procter.

Mr. Whelpley moved that the Chairman of the committee be furnished with a list of delegates to the State Associations, so that he might correspond with them and get up an organization for the furtherance of this fund. The Chair stated that it was hardly necessary to put this in the shape of a motion, and that he had no doubt the Secretary would be glad to furnish the Chairman with such list. The Secretary responded that the Association had no such list of delegates to the Association, but Mr. Whelpley said there was a motion to appoint them.

Mr. Hancock stated that at the meeting in New York the committee was empowered to enlarge itself, and asked if that was still the understanding, and the Chair replied in the affirmative.

The Chair called for the report of the Committee on Publicity as the next business in order, and Chairman Hays gave a brief verbal abstract of the committee's report, the full text of his report being as follows:

REPORT OF THE COMMITTEE ON PUBLICITY.

To the Officers and Members of the American Pharmaceutical Association:

Early in his administration President Rusby reappointed the old Committee on Publicity, consisting of Messrs. Caswell A. Mayo, Harry B. Mason, and the undersigned as Chairman.

Under date of October 11, 1909, he addressed the following letter to the members of this committee:

NEWARK, N. J., October 11, 1909.

To the Members of the Committee on Publicity of 1908–1909:

Will you kindly take into consideration the following suggestions concerning the relations of the work of your committee to that of some of the other committees of the Association.

The most perfect analysis of the situation that I have been able to make shows clearly
that the success of the Association depends directly upon the individual activities of the members, and is to a great extent proportional to the number of members. It is for this reason that I purpose devoting my special efforts as president to increasing the membership. No other influence can so greatly tend in this direction as the establishment of local branches. Successful work by the Committee on Publicity will exert a most favorable influence upon the establishment of such branches. It is of further great interest to your committee that by the plan that I shall suggest below, the establishment of the proposed local branches will develop entirely new opportunities for successful work by you.

I have carefully studied Chairman Hays' report and think that he has correctly diagnosed the causes of the failure of your committee to accomplish greater results.

The first cause as stated by him is the absence of means (funds) for carrying on the necessary work of the committee. Concerning this obstacle, I suggest a method of performing the work without incurring expense so that it will cease to be operative.

The second cause assigned is an absence of interest and co-operation on the part of the members of the Association. This difficulty is inherent in human nature and your committee cannot hope, any more than other workers, to escape its influence; yet, if all workers were to assign it as a valid reason for ceasing effort, no work could ever be accomplished. This difficulty must be met and overcome. In my opinion, the way to overcome it is to increase the number of, and to properly distribute those who are officially charged with the work and shall have willingly accepted its responsibility.

The third difficulty assigned depends almost wholly upon the two former, and will to that extent disappear with their removal.

With the above thoughts in mind, you will understand my hope, and I trust share it, that a more or less favorable result will follow from the plan indicated in the communication of which I enclose a copy. It is my intention to manifold this at my own expense and to send a number of copies each to persons in the leading towns and cities who are my personal friends and friends of the Association, and ask them to mail them to the leading newspapers, paying the small amount of postage involved. This will so distribute the expense for postage that no one will feel it. The reading and tabulation of the replies will be light work if the Committee on Publicity will share it.

In case the results prove disappointing, which is of course very possible, some good will at least have been done in bringing our Association to the attention of those editors. This benefit will amply repay the effort involved and will certainly make it easier for future operations to succeed. It is publicity work of a good sort. In that case, we can report the matter and let it drop. On the other hand, the responses may be so favorable as to justify acting on the proposed plan, or some modification of it, in which case the Committee of 1909-10 will score a great success and pave the way for important future results.

I write this to ask your candid opinion concerning the desirability of taking this action, concerning the propriety of making it the action of your committee; I'm merely acting as your aid, on the principle that the President is a member of all committees.

Finally, I would ask if you are willing to continue as a member of this committee during the coming year.

I have had a long conversation with Chairman Hays, who approves of the plan proposed and also of continuing the membership unchanged, except for additions. I should like to have Dr. Whelpley and someone in the far west, perhaps Prof. Johnson of Seattle, added to the committee.

Will you be so kind as to send me a reply promptly, as the shortness of the current year necessitates prompt organization.

Very truly yours,

(Signed) H. H. Rusby, President.
As intimated in the foregoing letter, President Rusby enlarged the Committee by adding to it Messrs. Henry M. Whelpley and C. W. Johnson. The president has not contented himself by appointing others to do the publicity work of the association, but has himself been a most earnest, active and valuable member of the committee.

The communication to which he refers in the foregoing, and of which he sent out about 200 copies to friends throughout the country, reads as follows:

October 9, 1909.

Dear Sir: This letter is written to many of the leading newspapers of the country, to inquire whether they would consider it of advantage to them to be able to consult, on such pharmaceutical matters as they may from time to time be compelled to consider, with local committees of this Association, appointed for the purpose. In submitting your reply, will you kindly consider the following facts:

This Association, unlike the National Association of Retail Druggists, that of Wholesale Druggists, the National Proprietary Association and similar bodies, is not primarily interested in the business side of pharmacy. Although it maintains a working section on commercial interests, its primary objects are scientific, educational and professional, its other sections being on Scientific Papers, Education and Legislation, (professional) Pharmacy and Dispensing and Historical Pharmacy. It has numerous committees engaged in similar lines of work. Its object is thus to combat the domination of commercialism and to improve the character, as well as the standing of the profession.

It is unfortunate for the public, as well as for the general standing of our own profession, that the press of the country generally has not recognized this important element in pharmacy, nor the steady, and of late great progress that it has made in education, legislation and general practice and in the abatement of abuses. It has been the custom of newspapers to be guided by the superficial appearances in pharmacy and to ignore the essential professional tendency. Thus the grossest errors have been made in reporting, and especially in discussing such matters. It is the belief of the writer that if there were a committee in each important locality that represented the best knowledge, judgment and intent of this Association, whose business it should be to hold themselves in readiness to respond to calls for information from the local press, much good result to all concerned. The personnel of such a committee could be made acceptable to the journals interested before appointing. Journals would in no wise be bound to accept the committee's views but would have the benefit of their knowledge and advice, which should prove of considerable value.

Should the replies to this letter indicate sufficient interest and approval of the proposition submitted, I will recommend suitable action at our next meeting, to be held on the fifteenth of May, in Richmond, Va.

Trusting you will favor me with an expression of your opinion,

Very truly yours,

(H. H. Rusby, President)

To this letter he received an even dozen replies by mail, as well as oral responses through representatives of two New York papers, the Times and the World. A summary of these replies, together with some comments made upon them by President Rusby, follows:

Newark, N. J., April 18, 1910.

SUMMARY.

Pittsburg Gazette Times. Glad to have our services.
Portland (Me.) Evening Express. Will be very glad to consult.
Nashville American. City too small.
Cincinnati Inquirer. Thinks it of no particular value.
Wilmington (Del.) Evening Journal. Will be glad to have benefit.  
Philadelphia Post. Have never found such necessity.  
Ogden (Utah) Evening Standard. Does not understand, but if information of public benefit, glad to publish it.  
Detroit Journal. Idea admirable, as it insures accuracy.  
Chicago Evening Post. Glad to consult.  
Atlanta Georgian. Hardly has any use, but favors plan.  
Minneapolis Journal. Suggestion good one and glad to have advantage.  
Boston Globe. Does not think it feasible.  
New York World. Glad to have benefit.  
New York Times. Just what is needed by papers and will be wanted when they understand it.

I will now state it as my opinion that the plan is practicable. These papers do not yet understand the nature or full measure of our possible assistance. It is not a plan which could be expected to yield large immediate results but they would steadily increase. If we had an energetic representation in a given city, it would become known to the pharmacists of that city as well as to the newspapers and would thus be of great benefit to our Association as well as to the profession. When any question came up between a pharmacist and the public, or between him and a paper, either could appeal to our sub-committee. If the latter found itself called upon to submit a statement to the press, its relation to our Association would give it standing, and the result could not fail to be good. Furthermore, statements are constantly appearing in the newspapers on botanical, chemical, toxicological and similar subjects having pharmaceutical relations. Pharmacists noticing errors in these could communicate them to our sub-committee which could report them to those papers which had previously agreed to recognize it, under such a caption as “pharmaceutical information corrected.” Our sub-committee could also extract similar criticisms which frequently appear in the pharmaceutical press and submit them to those journals which had agreed to accept our services. It is very certain that after a time other papers, especially those that were criticized, would see that the others were gaining credit for correctness in such matters and were becoming mentors to them.

At the same time that we and our work were thus becoming known to and appreciated by the press, the same thing would be happening to the pharmacists of the various sections, and this would tend to bring them into our Association.

I feel very sure that progress by such an organization as I have suggested would be sure and sound and would establish a new basis for the strength and growth of our Association.

On November 6th our President sent out a general letter to the chairman of his various committees. That portion of it of especial interest to the committee is here quoted:

“The Committee on Publicity will have important work to do in arousing public interest and demand for necessary legislation, and should have a sub-committee in every place where legislation is to be enacted. This committee has already received a communication from the President, suggesting a plan of action, in this direction, which every member of the committee has approved.”

Acting under the stimulus of President Rusby’s example and encouraging word, the chairman of the Committee, on December 3d, dispatched to each of his associates a letter similar to the following:

Dear Sir: In the report of the chairman of the committee on publicity made at the recent meeting of the American Pharmaceutical Association, three reasons or excuses were given for the unsatisfactory results of five years of labor by this committee, namely (1) lack of funds, (2) want of cooperation on the part of members, and (3) the seeming indisposition of the public press to concern itself with the affairs of pharmacy.
President Rusby is exceedingly desirous that the publicity committee accomplish something worth while during his term, and has appointed as such committee, yourself [Mr. Mayo], Mr. H. B. Mason, Dr. H. M. Whelpley, Prof. C. W. Johnson and the undersigned, the latter as Chairman. He thinks that by dividing the work among five members, to be further divided by these five among a much larger number, the question of expense will become so attenuated as almost to disappear, and that the other difficulties mentioned will be largely overcome. President Rusby is deeply in earnest about the work of the Association this year, and has inspired me with a determination to make our committee present a better showing at Richmond next May than it has ever been able to make before. That you will do what you can to bring about that end your record as an A. Ph. A. worker leaves no doubt.

The plan of campaign is as follows: The territory to be covered by our operations has been divided into as many parts as there are members of the committee, and we desire each member to request some loyal A. Ph. A. man in each town and city in his territory to act as his deputy and do the actual work of securing the proper kind of newspaper publicity for pharmacy in his town or city and its tributary country. If well done this work will not only arouse public interest in pharmacy and thus make desirable legislation easier, but will impress upon druggists the fact that the A. Ph. A. is accomplishing something for them, and so will attract members to its fold.

The territory assigned to you is the section, consisting of the States of

Of course you will know the best men to approach in this territory and how to approach them. Just as a suggestion, I am enclosing herewith copies of two letters written by President Rusby. You perhaps have already seen these, but it will do no harm and be a convenience for you to have them at hand just now.*

Strong local pharmacists can exert a greater influence over the newspaper men than can President Rusby or any other man in whom they have not even a remote interest, but the local men must be reminded of their duty and opportunity now and then or they will forget the one and neglect the other. Such local men are in a position to watch the papers, detect anything in them that reflects unjustly upon pharmacy, and to write to the papers letters having the authority of the American Pharmaceutical Association, for the purpose of correcting the wrong impression; they can take the initiative in laying before the public such things regarding pharmacy and the work of our Association as may redound to the benefit of the one and the credit of the other; and they can perform the services mentioned in President Rusby's letters.

Your work as a member of this committee is to appoint the local men for your territory and keep them reminded of what is expected of them, and to report the results of your and their labors to the Chairman. I trust that you will be able to inform me soon that you are "on the job," and that you do not intend to let your appointees rest until they have reported actual accomplishments to you and not even then, until the Richmond meeting. It is especially desirable that some live member at Washington and the state capitals be interested in this campaign, and wherever there are local branches their services should be enlisted too. We ought to have a scrap book full of clippings to show at the next meeting as a result of our efforts. I should be glad to have you communicate to me any idea for furthering this work that may occur to you, and I promise to pass the same along to the other members of the committee.

The time for activity is short. Let's start something, and start it soon and with a rush. Yours very truly,  

(Signed) FRANCIS B. HAYS.

To Mr. Johnson was assigned the territory made up of North Dakota, South Dakota,  

* The letters referred to are given above.

Mr. Whelpley's territory consisted of Nebraska, Kansas, Oklahoma, Texas, Iowa, Missouri, Arkansas, and Minnesota.

Mr. Mason's was Ohio, Indiana, Illinois, Michigan and Wisconsin.

Mr. Mayo's was Pennsylvania, Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Kentucky, Tennessee, Cuba and Porto Rico.

The Chairman took New York, New Jersey, the New England States and Canada.

Form letters were sent out to the druggists in his territory by each of the members of the committee, that mailed by Mr. Mayo and the Chairman being the same except as to the signature. Copies of all these are here given:

February 1, 1910.

Fellow Member of the A. Ph. A.: There is much work for the American Pharmaceutical Association to do. There is much work for its Committee on Publicity to do. There is much work for each of its individual members to do. Doubtless you as an active and loyal member of the Association would be glad to know how you can do more work for the organization. One way is by cooperating with the Committee on Publicity. This you can do without very much effort.

By way of explanation I may say that this Publicity Committee was created several years ago, but has never accomplished much. Its Chairman last year gave three reasons for this want of material accomplishment: one being lack of money, another, seeming lack of interest in pharmaceutical matters on the part of the daily press, and the third, lack of cooperation with the committee on the part of the members at large. At first President Rusby was inclined to discontinue the Committee on Publicity, but upon further consideration he devised a plan which he thought might overcome the three difficulties encountered by the Association's publicity promoters in former years, and appointed a committee of five to help put this plan into execution. The country has been divided into five sections, each one of which is in charge of a member of this committee. You are in my section. Each member of this committee is to appoint as many sub-committeemen as he sees fit, and these are expected to get in touch with the daily papers published in their territories, respectively, for the purpose of getting the desired kind of publicity for the Association. What a sub-committeeman's territory is he can judge by studying the lists in the back of the A. Ph. A. Proceedings in which the states and towns of our members are given. If two members lap over into each others' territory, no harm will be done.

This plan, as you see, divides the expense (for postage, etc.) of the committee that it will not fall heavily upon anybody, and thereby does away with the need for funds; it is devised to bring a local influence to bear upon the daily press which ought to result in awakening its interest in pharmaceutical matters: and we trust that you and others who are appointed sub-committeemen will see that the third object disappears automatically.

So much for the general plan. Now to get down to particulars as to what you, who are hereby appointed a sub-committeeman, are expected to do. We want to show to the public that the drug business is not what the usual newspaper joke or news item would lead readers to suppose; we want to defend the good name of druggists in cases in which it can be defended and to let the public know that the black sheep in the business not only are not representative of, but are not in good fellowship with the others; we want to watch the papers for attacks on the drug business and by doing what we can through the papers to repulse these attacks, to raise the business in the estimation of the public and to raise the work of the American Pharmaceutical Association as a practical, neces-
sary body, in the estimation of those druggists who now seem to regard it as being of no value to the rank and file. For instance, suppose one of the newspapers in your territory should charge that the drug business is merely a cloak for the sale of liquor. It would then be an opportune time for you to write a letter to that paper and quote the resolution adopted by the A. Ph. A. against the illegal sale of liquor in drug stores (Proceedings for 1908, page 535). There are lots of ways in which you can render valuable aid to pharmacy and the Association through your local newspapers which will occur to you from time to time, and which it is not necessary that I should point out to you in detail now. By combining the name of the Association with your own in this work you can probably exert more influence than if you acted simply in your personal capacity, and by thus utilizing your services the Association will be getting work done which it could not accomplish in any other way.

I should be glad to have you promise that you will undertake this work, and to have an account of all that you do—together with press clippings and copies of your letters—to be embodied in the report of our chairman to the meeting of the Association to be held at Richmond, Va., May 2d to 6th.

You may feel that what you may be able to accomplish will hardly be worth while, but just think what an influence for good will be exerted if work of this kind is undertaken in every city, town and village in the country in which we have a member. And, as President Rusby says, even if we do not accomplish what we want to, we shall at least be doing preliminary work which will make it easier for those who are to follow us to do more, and we shall be letting the newspapers know that there is such a thing as the A. Ph. A., and that it is a militant organization of those who regard the practice of pharmacy as something better than dealing in questionable merchandise.

Fraternally yours,

Caswell A. Mayo.

THE BULLETIN OF PHARMACY.

DETROIT, MICH., December 15, 1909.

Dear Sir: President H. H. Rusby, of the American Pharmaceutical Association, has planned to make his administration one of great aggressiveness and value. He has called upon the Committee on Publicity for certain definite work, and it is in my capacity as a member of this committee that I am approaching you.

You have been appointed the representative of the Committee on Publicity for your city, and I trust that you will give us hearty co-operation. What is there for you to do? This:

Watch the newspapers whenever they touch upon any subject affecting pharmacy. If you detect things which reflect unjustly upon our profession, correct the situation at once by writing letters for publication having the authority of the A. Ph. A. behind them. More than this, take the initiative in laying before the public, through the medium of your local newspapers, such things regarding pharmacy and the work of our Association as may redound to the benefit of one and the credit of the other.

This isn’t much, and I hope you will be willing to do it. The American Pharmaceutical Association is the great conservator of professional and ethical pharmacy in the United States. Its noble work for the benefit both of the profession and the public ought to be more widely known among the people generally. The Association ought also to get more credit among druggists themselves for services accomplished.

You will help us attain these objects if you will kindly take your appointment seriously and endeavor to assist us in the manner indicated. In a word, write a letter for publication to your local newspapers whenever the occasion presents itself to you, and in these letters do not fail to set forth the worth and the dignity of pharmacy and the uplifting work accomplished by the American Pharmaceutical Association.

Finally, will you please send to me clippings of all such letters, in order that I may
turn them over for permanent preservation in the archives of the Committee on Publicity. The committee is anxious to render a ringing report at the Richmond meeting next May. We need your co-operation. May we count on it?

Very cordially yours.

Dear Sir: The Committee on Publicity of the A. Ph. A. has as its prime object the establishing of a better understanding between the public at large and pharmacists, so that the customers of the retail drug trade will understand the nature of the calling which is designated as "pharmacy." You must have realized before now that the newspapers do not always give pharmacy credit for the position which it holds in the affairs of a community. The calling is often misrepresented.

I am a member of the General Committee on Publicity, and have been requested to appoint associate members in this section of the country. I have selected you because I know of your interest in pharmacy and your ability in making "crooked things straight," and I hope that you will straighten out the public opinion of pharmacists. This you can do by getting in touch with as many editors as possible who control the expressions in Nebraska newspapers. Notify these editors to consult you on pharmaceutical matters before they rush into print with their expressions.

In cases which justify it I suggest that you write newspapers communications for publication, commenting on misleading statements in regard to pharmacy which you see in print. In doing so you are at liberty to sign your name as a member of the A. Ph. A. Committee on Publicity.

A second object of our committee is to promote the welfare and influence of the A. Ph. A. This you can accomplish by talking the A. Ph. A. to your associates at conventions. This should be done in both local and state meetings.

I suggest that you send direct to the Chairman of our committee, Francis B. Hays, 160 William St., New York City, either the original or copies of the letters which you receive from editors and clippings from newspapers when articles are published relating to pharmacy.

I trust you will write me freely after you have studied the situation. The work of this committee is necessarily very much like advertising. It is difficult to measure the net results by any known standard, but we are anxious to submit a proof at Richmond which will show that the committee has been active and made the best of its opportunities.

Very truly,

UNIVERSITY OF WASHINGTON.

School of Pharmacy, Charles W. Johnson, Ph. C., Ph. D., Dean, University Station, Seattle, Washington.

Dear Sir: The committee on publicity of the American Pharmaceutical Association is trying to cover every section of our country this year to bring the association to the attention of every druggist and others who are interested. To do this the work of the committee is divided into sections. You are located in my territory and I would like to ask you to do what you can to further the interests of the association in your community. Some of the points which you may be able to cover are as follows:

1. See that the newspapers of your community report items concerning pharmacy correctly. Should misstatements occur in the papers you should endeavor to have correction made and the position of the A. Ph. A. made clear on the point involved.

2. If you have a druggists association in your city you should bring the work of the A. Ph. A. to its attention and try to get all druggists sufficiently interested that they will become members.

3. In the same way speak to the physicians and give them an outline of what is being done by the association in its various sections and lines of work.
You may think that you can accomplish very little that will be noticeable but if every A. Ph. A. member would do something along this line our association would soon be of much greater power than it is today. I trust that you may be able to give the association a part of your time and that you will solicit the aid of other druggists along this line.

Respectfully,

Member of Committee on Publicity, American Pharmaceutical Association.

F. B. Hays, New York, N. Y., Chairman of Committee.

February 1, 1919.

fellow Member of the A. Ph. A.: There is much work for the American Pharmaceutical Association to do. There is much work for its Committee on Publicity to do. There is much work for each of its individual members to do. Doubtless you as an active and loyal member of the Association would be glad to know how you can do more work for the organization. One way is by cooperating with the Committee on Publicity. This you can do without very much effort.

By way of explanation I may say that this Publicity Committee was created several years ago, but has never accomplished much. Its Chairman last year gave three reasons for this want of material accomplishment, one being lack of money, another, seeming lack of interest in pharmaceutical matters on the part of the daily press, and the third, lack of cooperation with the committee on the part of the members at large. At first President Rushy was inclined to discontinue the Committee on Publicity, but upon further consideration he devised a plan which he thought might overcome the three difficulties encountered by the Association's publicity promoters in former years, and appointed a committee of five to help put this plan into execution. The country has been divided into five sections, each one of which is in charge of a member of the committee. You are in my section. Each member of this committee is to appoint as many sub-committee men as he sees fit, and these are expected to get in touch with the daily papers published in their territories, respectively, for the purpose of getting the desired kind of publicity for the Association. What a sub-committeeman's territory is he can judge by studying the lists in the back of the A. Ph. A. Proceedings in which the states and towns of our members are given. If two members lap over into each others' territory, no harm will be done.

This plan, as you see, so divides the expense (for postage, etc.) of the committee that it will not fall heavily upon anybody, and thereby does away with the need for funds; it is devised to bring a local influence to bear upon the daily press which ought to result in awakening its interest in pharmaceutical matters; and we trust that you and others who are appointed sub-committee men will see that the third obstacle disappears automatically.

So much for the general plan. Now to get down to particulars as to what you, who are hereby appointed a sub-committeeman, are expected to do. We want to show to the public that the drug business is not what the usual newspaper joke or news item would lead readers to suppose; we want to defend the good name of druggists in cases in which it can be defended and to let the public know that the black sheep in the business not only are not representative of, but are not in good fellowship with the others; we want to watch the papers for attacks on the drug business and by doing what we can through the papers to repulse these attacks, to raise the business in the estimation of the public and to raise the work of the American Pharmaceutical Association as a practical, necessary body, in the estimation of those druggists who now seem to regard it as being of no value to the rank and file. For instance, suppose one of the newspapers in your territory should charge that the drug business is merely a cloak for the sale of liquor. It would then be an opportune time for you to write a letter to that paper and
quote the resolution adopted by the A. Ph. A. against the illegal sale of liquor in drug stores (Proceedings for 1908, page 535). There are lots of ways in which you can render valuable aid to pharmacy and the association through your local newspapers which will occur to you from time to time, and which it is not necessary that I should point out to you in detail now. By combining the name of the association with your own in this work you can probably exert more influence than if you acted simply in your personal capacity, and by thus utilizing your services the association will be getting work done which it could not accomplish in any other way.

I should be glad to have you promise that you will undertake this work, and to have an account of all that you do—together with press clippings and copies of your letters—to be embodied in the report of our Chairman to the meeting of the association to be held at Richmond, Va., May 2d to 6th.

You may feel that what you may be able to accomplish will hardly be worth while, but just think what an influence for good will be exerted if work of this kind is undertaken in every city, town and village in the country in which we have a member. And as President Rusby says, even if we do not accomplish what we want to, we shall at least be doing preliminary work which will make it easier for those who are to follow us to do more, and we shall be letting the newspapers know that there is such a thing as the A. Ph. A. and that it is a militant organization of those who regard the practice of pharmacy as something better than dealing in questionable merchandise.

Fraternally yours,

FRANCIS B. HAYS.

Mr. Whelpley wrote that he did not use the same form letter in all his correspondence, but that the general form he sent covered all points he has tried to make in writing to his sub-committee men. Of course a special personal communication is much better than a form letter.

The chairman sent a copy of the form letter of each member of the committee to all the other members.

Members have doubtless already seen the letter from the chairman published in our Bulletin for March, page 137, a copy of which is attached hereto:

AN OPPORTUNITY FOR EFFECTIVE AND PROFITABLE PUBLICITY WORK.

100 WILLIAM STREET, NEW YORK, FEBRUARY 24, 1910.

TO A. PH. A. MEMBERS:

There has never been a better time than right now for members of the American Pharmaceutical Association to do a little effective publicity work for themselves and the Association. The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is opposing certain unethical practices on the part of some druggists, suggesting that physicians discipline the persistent offenders by using a very persuasive means easily within their reach.

It would be of service to pharmacy if every member of the American Pharmaceutical Association would let it be known through the newspapers that the Association is not in sympathy with any unethical practices on the part of druggists, and that no loyal member of the Association indulges in them. This may be done in the larger cities through the correspondence columns of the papers, while in the smaller places personal interviews with the editors might prove more effective.

Pharmacy can not afford to let this latest attack upon its votaries go unchallenged, and the member of the American Pharmaceutical Association who can and does show that so far as he is concerned it is unwarranted, will by so doing not only aid in raising pharmacy and the association in the estimation of physicians and the public, but will be doing himself a good turn which ought to pay him in dollars and cents.

FRANCIS B. HAYS, CHAIRMAN A. PH. A. COMMITTEE ON PUBLICITY.
As to results, we wish it were not necessary for us to speak, as they seem to be so inadequate, considering the voluminousness of the report of what has been done to achieve them. Still, bread cast upon the waters has been known to show itself again after many days, and with a goodly increase. Work of a more persistent and methodical nature than the members of this committee have the time to do, would doubtless show greater achievement than we are able to report.

But there have been some returns. President Rusby is encouraged by the results of his campaign, and the members of the committee report that they have seen some effect of their labors.

From the nature of the work of this committee, its report is necessarily a one-man paper.

FRANCIS B. HAYS, Chairman of the Committee on Publicity.

RICHMOND, VA., May 7, 1910.

Mr. Payne complimented the committee upon the good work it had done, and said he did not know why it was, but had noticed that the papers in his State had made very nice notices.

Mr. Whelpley related an amusing experience he had had in dealing with the daily press in St. Louis in this behalf, and the Chair spoke of his experiences in New York City, and related the circumstance of a representative of one of the daily papers calling on him and making the statement that they were often called on to write something and didn't know what to write, and if they could get information from such a society as this, they would take their advice.

Mr. Francis moved that the Association express its obligation and appreciation of the many courtesies shown in the report of the operations of this society by the daily press of Richmond, and that notification be sent to the editors of each of the Richmond papers of such action. This motion was seconded by Mr. Mayo and carried.

The Secretary called for the report of the Delegates to the National Wholesale Druggists' Association, stating that he had not received their report. There was no response.

The Secretary called attention to the fact that a motion had been made by Mr. Hynson to amend Articles II and V of Chapter IX of the By-Laws, and also Article I of Chapter X. These proposed changes were necessary to carry into effect Mr. Hynson's motion to change the name of the Section on Commercial Interests to that of Section on Ethics and Practice, provided said motion prevailed. He said that Mr. Hynson had requested him to suggest that this matter be referred to the Council—not to be adopted, but referred to the Council.

Mr. Holzhauer said he hoped this would be voted down. He thought it was out of the question to change the name of the Section on Commercial Interests to that of Section on Ethics and Practice, for the pharmacists interested in commercial matters would never think of going to a section bearing the latter name to hear commercial matters discussed. He called for a vote on this proposition.
Mr. Hallberg moved to refer to the Council, with an expression of disapproval on part of the Association, and this motion was seconded by Mr. Wilbert.

Mr. Mayo thought a motion to amend the By-Laws could not be disposed of in the way proposed by Mr. Hallberg—that all such motions must be acted upon by the Association.

The Chair stated that as the matter now stood, there was no motion to adopt. Thereupon Mr. Whelpley so moved, and was duly seconded.

Mr. Ford moved as a substitute that this motion to amend the By-Laws be not adopted, and Mr. Whelpley seconded this motion. The Chair put the vote on the Ford motion, and it was carried unanimously, and the Chair declared the motion to amend the By-Laws had failed.

Mr. F. B. Hays presented his report as Reporter to the Public Press, as follows:

REPORT OF THE REPORTER TO THE PUBLIC PRESS.

To the Officers and Members of the American Pharmaceutical Association:

Richmond papers have handled the news of our meetings better than those of any other city in which we have met during the five or six years that we have had a reporter to the public press. In Indianapolis, in 1906, one paper did very well indeed; in 1907, New York hardly found out that we were within her ample walls; at Hot Springs the following year the newspapers were like the beggar in the story, who would take the corn if it were shelled—they were willing enough to print what your reporter gave them, but seemed to have no facilities for getting the news; last year the Los Angeles papers treated the Association in a more or less sensational way, and not methodically.

There are four daily papers in Richmond, one morning and three afternoon. Your reporter called upon the city editor of each of them the first thing after reaching the city Monday morning, and was most courteously received. He invited these editors to send reporters to the meetings and have them call upon him for any assistance they might need. He also gave to each of them a different short preliminary “story” as to the scope and object of our Association, which in each instance was published before our opening session.

All the papers had active and competent men attending our meetings each day, and have featured their accounts of our proceedings almost every day on their first pages, as members have doubtless noticed.

What the Associated Press and United Press have done your reporter does not know, as he has not followed the out-of-town papers during the meeting.

The four Richmond daily papers—the Times-Dispatch, the News Leader, the Evening Journal and the Virginian—are entitled to our thanks for their liberal and just accounts of our proceedings.

A complete set of clippings from these papers has been made by your reporter and will be turned over to the historian.

Respectfully submitted, FRANCIS B. HAYS, Reporter for the Public Press.

RICHMOND, VA., May 7, 1910.

The Chair stated that, so far as he knew, there was no more business to come before the Association at this meeting.

Mr. LaWall, of Philadelphia, stated that, in connection with the report
of the Committee on Reorganization, he had a set of resolutions he wanted
to offer, though he did so with some diffidence, for fear it might precipi-
tate a discussion. He thought it was a matter which was of vital interest to
the work of the Association, however, and he would like to present them:

Resolved, That the Committee on Reorganization of the A. Ph. A. take into considera-
tion a plan by which:
1. The sessions of the various sections after having been assigned a certain time be
not interfered with by simultaneous council meetings.
2. That no general social functions be scheduled for hours assigned to general or
section programs.
3. That a uniform plan of procedure be provided by which each section is authorized
to proceed according to the order of the program for any particular session, any unread
papers to be deferred until the completion of the program arranged for the subsequent
session.
4. That some satisfactory method of signaling the opening of sessions, either by
megaphone, trumpet or bugle call, be adopted.
5. That a method of announcing, by blackboard or similar notice, to members in
attendance at each simultaneously occurring session, the titles of papers which are being
read at all of the other simultaneous sessions.

Mr. Wilbert moved to refer to the Committee on Reorganization, for
consideration and report next year, and this motion was seconded by Mr.
England and carried.

Mr. Payne stated that before the Association adjourned, he wanted to
offer a resolution that a standing vote of thanks be extended to the Local
Secretary, his assistants, and all of the pharmacists of the city of Rich-
mond, their families and friends; the Governor, Mayor and other officials,
and the press, for their uniform kindness and many courtesies shown the
members of the Association during their stay in Richmond. There were
several seconds to this motion. Mr. Mayo stated that, in seconding this
motion, he felt that words could not express the pleasure that many of
the members had experienced in this meeting at Richmond. He did
not know of any occasion when all the members had so thoroughly en-
joyed themselves, and the only drawback had been that the stress of busi-
ness had been so great that some of the members had been deprived of
the pleasure of participating in the entertainment features that had been
provided so bountifully. He was sure that every member, and every
lady in attendance, had a delightful time.

Mr. Hallberg also seconded the motion, and said he thought the Asso-
ciation should be especially thankful to the Local Secretary and the Com-
mittee of Arrangements for not interfering with the business of the Asso-
ciation. Mr. Wilbert endorsed this sentiment.

Mr. Roehrig moved that the hotel management also be included in this
vote of thanks, and Mr. Payne gladly accepted the amendment. The
Chair stated he was very glad to hear the suggestion, for the management
certainly deserved it.
Mr. Payne's motion as amended was then put to a vote and carried unanimously.

The Chair stated that before calling the newly-elected President to the Chair, he wanted to express his own very hearty thanks to the workers of the Association for what they had done during the year just closing. He said it was feared at first that the work of the year would be curtailed, because of the short time since the last annual meeting—only some nine months—but he had called on the various committees and workers to take that fact into consideration and "get busy," and they had responded generously, as was evidenced by the great amount of work accomplished. This work had been done at great personal sacrifice in many instances, and he wanted to thank those who had done it so well.

The Chair then called on Mr. Payne and Mr. Day to act as a committee of escort to conduct the President-elect and other officers to the rostrum, that they might be duly installed into the offices for which they had been selected.

These gentlemen performed this duty handsomely, and first escorted to the Chair President-elect Eugene G. Eberle, of Dallas, Texas, whom Mr. Payne, introduced as "a remarkable man from a remarkable State—Mr. Eberle, of Texas." (Applause.)

Mr. Eberle expressed his hearty appreciation of the honor paid him in his election to the office of President, and said he would endeavor during the year to handle the business of the Association that came to him with the greatest care possible, and would be appreciative of any assistance or advice that might be given him by the members. He begged that they would not hesitate to communicate with him at any and all times about Association matters, and assured them they would have a respectful hearing. Mr. Eberle stated that he thought the Association had entered upon a new era: that while the work that had been done in the past, and the tremendous amount of work that had been done at this meeting, after so short a space of time since the last meeting, was remarkable and highly encouraging; he was especially gratified at the culmination of a movement that many, and perhaps most, of the members had been looking forward to for some years past, namely, the establishment of a Journal of this Association. He felt that this would result in a material increase of the membership of the Association. It was something that would appeal to prospective members—far more so than the annual Proceedings, necessarily so long delayed in transmission; for they would at once see the value of such a Journal. He was very hopeful of its effect. Mr. Eberle said it was his purpose to give a large part of his individual effort towards an increase of membership, especially throughout the Southern States, where the membership was rather light. He commended the passage of a resolution at this session, authorizing the President to appoint a special representative at the annual meeting of each State Association, to speak
for the American Pharmaceutical Association, and take up this matter of membership in a systematic way. This method had already been adopted in Texas with good effect, and he had no doubt it was true of others of the states, but he thought it highly desirable to extend it to all State Associations. He also thought it would be a good idea to get in touch with the graduates of the various schools of pharmacy, and put copies of the Journal of the Association in their hands. Mr. Eberle again expressed his thanks to the Association, and hoped that when his year of service was ended, he would still be found worthy of that high esteem in the eyes of the members indicated by his selection for the office of President. (Applause.)

The Chair, suiting the action to the word, said it afforded him great pleasure to pin the badge of the President upon Mr. Eberle's coat, this being the second time Mr. Eberle had worn this badge of honor in the past year, as, in the capacity of First Vice-President, he had presided at the Los Angeles meeting last year, by reason of the enforced absence of President Oldberg. "Look out that you do not have a dictator!" said Mr. Rusby.

The Chair then introduced Vice-President William B. Day, of Chicago. Mr. Day assured the members of his high appreciation of the honor conferred upon him in naming him for First Vice-President, and said he would do all that he could to promote the interests of the Association in every way possible during the coming year.

Second Vice-President Otto F. Claus, of St. Louis, was not present, but Mr. Payne, of the committee, introduced Mr. L. E. Seltzer, of Detroit, the Third Vice-President-elect to the Association.

Mr. Seltzer said he thought it went without saying that the Third Vice-President should be seen and not heard, but that he simply wanted to take this opportunity to thank the members for the recognition they had given him, however undeserved.

The Chair announced that the next officer-elect to be introduced to the Association was Treasurer Whelpley, who had succeeded himself. Mr. Payne introduced the gentleman.

Mr. Whelpley said that he had been so interested in the initiatory ceremonies that he had entirely forgotten that he himself was on the program to be installed. But he recalled especially the remarks of the President-elect, Mr. Eberle, to the effect that his efforts during the coming year should be largely in the direction of securing new members. It was the duty of the Treasurer to spend a large part of his time and energies in the direction of retaining old members, and much of his work had been directed to that end. He desired to especially thank the members in different parts of the country whose hearty co-operation with his efforts had resulted in saving many members to the Association who would otherwise have been lost; and he was pleased to see it demonstrated that all over
this country the Association had members who were anxious and willing to assist in this work. Some of the most pleasant experiences he had had during the year were in the responses from members who had expressed their willingness to co-operate with the Treasurer in this direction. Continuing, Mr. Whelpley said that the care of the special funds of the Association, which now had reached nearly to the sum of $30,000, was one that demanded considerable attention on the part of the Treasurer and the Special Committee on Invested Funds. He said that the future prosperity of the Association along enlarged lines would be possible through these special funds, and he could see now why former Treasurer Sheppard laid so much stress on this feature of Association work. Now at the close of his second term as Treasurer, he realized many things that he did not understand before, and realized why Mr. Sheppard always paid such close attention to everything that was proposed that meant expense to the Association, and why he took a special interest in everything that meant new members. He wanted to repeat what he had said last year at Los Angeles, that the greatest inspiration he had had for his work in the Treasurer's office was the record of his able predecessor.

The Chair stated that the next officer to be installed was the veteran Reporter on the Progress of Pharmacy, Mr. C. Lewis Diehl, of Louisville, and that he could not promise the Association that this gentleman would do his work any better than in the past, because he did not think he could do it any better. He did believe, however, that the new arrangement for the publication of a Journal would enable him to do his work easier, and he congratulated him upon that.

Mr. Payne introduced Mr. Diehl in his usual felicitous style, and Mr. Diehl thanked the members for the honor conferred upon him, assuring them that, as in the past, he would try to do his whole duty, and if he could improve upon his work in any way he would do so.

The Chair stated the new Chairman of the Council, Mr. J. H. Beal, was not present, and, therefore, could not be installed; nor was Mr. J. P. Remington, the second of the newly-elected members of the Council present. This left the Chair alone to represent that body. Mr. Payne, of the committee, thereupon proceeded to introduce Mr. Rusby to the Association, as a man upon whom the Association had conferred every honor it could confer.

Mr. Rusby spoke of the work of the Council. He said it had been suggested that the Council should not hold its sessions at the same time the Sections did, but he wanted to say that if that proposition carried the Association could not have its business properly attended to. The Council was a hard-working, deliberative body, and it had necessarily had to consume a great deal of time at this meeting to do the work it had found necessary to accomplish. He said he hoped the Association would remember these facts, if a motion to curtail the time of the Council was ever made.
The Chair called on Mr. Payne to introduce the Secretary-elect, Mr. Charles Caspari, Jr., of Baltimore, stating that this should have been done before, but by oversight it had been omitted.

Mr. Payne introduced Mr. Caspari as a faithful officer, who needed no introduction to the members, and Mr. Caspari expressed his deep appreciation of the continued confidence of the members, saying that he looked back with a great deal of pleasure over the past 16 years in which he had been called on to serve in the office of Secretary. He said the best thing he could say was to express the wish that the coming years would be as successful as the past. He also expressed the hope that the relations between himself and the new President might be as pleasant and as fruitful of good results as they had been in the past with his predecessors.

President-elect Eberle here took the Chair as the presiding officer of the Association.

Mr. Ford, of Denver said he wanted the distinction of first addressing the new President, and moved that a vote of thanks be extended the retiring President and the other retiring officers, whose services to the Association justly entitle them to such recognition.

This motion was seconded by Mr. Hallberg, and Mr. Roehrig moved that the Association take a rising vote. The Chair thereupon put the vote upon Mr. Ford's motion, and it carried by a unanimous rising vote.

The Chair asked if there was any other business, before the Association, and the Secretary stated that he knew of none.

Ex-president Rusby briefly expressed his thanks for the kind tribute just paid him, and said he felt that he might include in this expression of thanks those of the other retiring officers.

The Chair stated that if there was no other business to come before the Association, a motion to adjourn would be in order. He said he was sure the members would take away with them a happy recollection of their stay in the city of Richmond, and carry with them a sense of satisfaction at having done such exceedingly good work. He had watched the work of the Sections, and he did not remember to have seen closer attention given to the work of the Sections anywhere than at this meeting. As far as he knew the work had passed off well, and he hoped to the satisfaction of everybody.

Thereupon Mr. Hallberg, seconded by Mr. Hays, moved that the Association's Fifty-Eighth Annual Meeting adjourn sine die, and the motion prevailed.
MINUTES
OF THE
SECTION ON COMMERCIAL INTERESTS.

FIRST (ONLY) SESSION—TUESDAY, MAY 3, 1910.

The Section on Commercial Interests convened at 3 o'clock, p. m., in the Auditorium of the Jefferson Hotel, and was called to order by Waldo M. Bowman, of Toledo, Ohio, Chairman.

The Chairman: Inasmuch as neither the Secretary of the Committee, nor any one of the three associates is here, I will ask Mr. W. W. Miller, of Richmond, to act as temporary Secretary; and I will call on Mr. Apple, of Philadelphia, to sit as an Associate on the Committee, if he will. I would like also for Mr. Apple to take the Chair, while the Chairman reads his address.

Mr. Apple being in the Chair, and Mr. Miller acting as Secretary of the meeting, Chairman Bowman here read the following:

THE CHAIRMAN'S ADDRESS.

It is a far cry from coast to coast, and a long journey from sunny Los Angeles to historic Richmond, yet the greeting of the pharmacist on the one coast differs not a great deal from that of his brother on the other, and the problems of the profession with the questions that ever arise are with us always. I do not think it is inopportune for me to again call your attention the fact that the Section on Commercial interests represents the actual moving power of this Association that it is this section that must, in the end, carry out the work as proposed by the other sections: For legislate as you will, and experiment as you will, the men who must bear the brunt after all, in the education of the public; in securing the co-operation of the physicians; in the support of the various activities of the government in its work for purer drugs, are the commercial men, who, looking after the working end are in touch with the consumer. As soon as we elevate the commercialism of pharmacy to its true level and find a means of holding it there, and not before, will the profession come to its own. You know how well and how often it has been proven that the college which places its graduates in a position to step into the current of every-day activities, is the one whose power is most felt, and the engineer with the keen insight into the working needs of his profession is the one who makes his name stand out, clear cut, and above the level of his associates. So it must be always and ever; the teacher works through his pupils, the school through its graduates, and the brunt of the labor falls on the man who serves his fellows in the

(571)
every-day work of life. We must elevate our commercial standing before we can improve our professional standing.

The last year has seen the growth of pernicious advertising of a certain class of preparations, to a point where the wonder is that the public will stand for the insult to its good judgment. In the East a new danger has shown forth in the growing strength of the "Chain Store" problem, and this has brought forth a suggested remedy that will, as far as the uplifting of pharmacy goes, surely breed a disease more pernicious than the one it seeks to cure, for in "Democratic America" (if you please), no combination exists for long with a clean "Bill of Health" where its base rests on the earning power of the dollar, and your syndicate working for the eradication of one evil will surely breed the germ of a pestilence far reaching and virulent.

As time goes on the question of Labor, threatening in all lines, becomes more and more a factor in commercial pharmacy, for, with but meagre attraction in the matter of wages, the fewer advantages in other ways, the long hours and few holidays, the number of competent men who take up the work becomes fewer and fewer in proportion to the demand. This condition the colleges can not remedy, the cure must come from the trade body. The increased cost and scarcity of a largely increasing number of our native drugs brings us face to face with a fact that we persistently ignore; that if we are to continue the use of our native drugs we can not much longer draw on lavish nature alone, but must aid and abet her in the conservation of her resources, and must take up the cultivation of a number of our native drugs for commercial purposes.

We must remember that this is not the work of a day nor a year, possibly the working out on a basis of commercial profit is not the work of a life-time, but looking forward into the future the need becomes very apparent, and I would suggest that this Section appoint a committee to look into the subject and gather such information as may be obtainable reporting same to the Association. This will open a most interesting field of work and the subject becomes so virile that it would be well worth the while of the Association to take some steps toward the giving-out of information in detail on the possibilities of the cultivation of certain native drug plants for commercial purposes. I am well aware that the Dept. of Agriculture is working along these lines, but there need be no conflict of interest. The so-called drug departments of the large stores in the cities are an eyesore to the pharmacist, they are used as an advertising medium for the stores rather than a source of income, their work is done by cheap labor, their whole tendency is toward prejudicing the public against the legitimate pharmacist. When we find these departments working with the active support of the wholesale drug trade we are forced to believe that the effort to interest the wholesaler in the work of this Association is a failure, and when we find these departments furnishing misbranded drugs and inferior articles we as an association should condemn them in no uncertain way. The increasing traffic in opiates and narcotics in spite of the efforts of the authorities to curb their sale, makes it obligatory on us to avoid even the appearance of evil, and to absolutely refuse to countenance the sale of such drugs except through the prescription department.

What are you doing through your State Associations toward the elimination of trade evils? What in your local societies for the purification of commercial pharmacy? What are you doing for yourself, Mr. Pharmacist? Pertinent questions, you say! Yes; they are pertinent questions, but they are dominant questions as well, and they are questions that you dare not ignore for long.

The medical profession, in a way, is seeing things in a clearer light, and is waiting your advances. The status of this Association is becoming clearer and its influence will continue to advance through the elevation of standards of purity. Even now the daily press and the magazines are beginning to heed the demand for the elimination of obnoxious advertising. Can you close your ears to the cry; your eyes to the light? Will you wait for an extraneous force to lift you from yourself? Do you stand like the
DISCUSSION OF THE CHAIRMAN'S ADDRESS.

Norseman waiting for the “warning from the winds?” Why wait for “the voice of one long dead” to tell you of your loss? Why die awake? Don’t do it! Stand up! To the possibilities of commercial pharmacy, to the justification of your own good name! And remember that “a good name is more to be desired than great riches,” even in modern America with its greed for getting and its God in the almighty dollar.

THE CHAIRMAN pro tem.: Gentlemen, you have heard the address of the Chairman of this Section. What disposition shall be made of it?

MR. LOWE: I move that it be received and referred to the Publication Committee.

MR. HYNSON: It seems to me that an address like that, which shows so much thought, should receive a little more attention. I believe the Chairman has written it believing what he has said to be true, and would be glad to hear us discuss it a little, would you not?

THE CHAIRMAN pro tem.: The motion has been duly made and is now open for discussion, if any is desired.

MR. HYNSON: I simply want to say, from the experience I have had, and some little effort I have put forth, that I think it very unfair not to discuss a paper like that and discuss it fully, and I would suggest that the Chairman read again to the meeting such parts of his address as deal with what he feels to be the most important points, and let the Section take such action as it sees fit. I make the motion, that the Chairman be requested to read such parts as he deems most important, and that the meeting discuss these parts seriatim.

Motion duly seconded and carried.

MR. BOWMAN: The Chairman thanks you very much for the interest you have shown in his address. One thing is certain, that unless the American Pharmaceutical Association does interest the commercial men and the pharmacists to a much greater extent than it has succeeded in doing in the past, the good it is going to do will be limited on every hand. I think the Association, as a whole, recognizes that fact. I know that the commercial men who do take an interest in the work of the Association recognize that fact.

I will first take up this part of my address; I say:

"The last year has seen the growth of pernicious advertising of a certain class of preparations, to a point where the wonder is that the public will stand for the insult to its good judgment."

THE CHAIRMAN pro tem.: The question is, gentlemen, whether you will now care to discuss that particular matter before you hear a paper which I find, upon looking over the program, will be read before another section, and which I think just touches on this same subject.

MR. BOWMAN: There is a paper that touches this question, but inasmuch as this Section is only to present five original papers, and as the Section on Practical Pharmacy and Dispensing finds itself somewhat hampered in their two sessions, their Chairman and myself have come to an agreement by which we will give over the time allotted for our second session, to the Section on Practical Pharmacy and Dispensing, and combine our session tomorrow afternoon with that of their Section, so in all probability the paper in question will not be presented except by title.
THE CHAIRMAN pro tem.: That being the case, we will take this matter up and discuss it at this time, as it will unquestionably not come up for discussion at a later stage.

MR. BOWMAN: I might say that what seems to me to be the meanest and most insulting class of advertising, to the public, that has come about of late years, has been that which has appeared recently in the Ohio papers, and I presume in other papers, purporting to be answers by physicians to questions which have been mailed to them, and advertising from eight to ten remedies in the daily press. That, to me, is the absolute limit of that kind of advertising. It is an insult to the public.

MR. HYNSON: I would like to ask the Chairman if he has thought of any means for remedying the evil.

MR. BOWMAN: I must say I have not.

MR. BODEMANN: That question has come up in the Ohio Association, in a similar shape, and it was recommended by the Trade Interests Committee that a bill be prepared and introduced in the State legislature, requiring that all such stuff as that should be printed for what it is worth—have it marked as an "ad," and not have it appear in the paper as an editorial opinion or as reading matter. A similar step has been taken by the Civic Federations in San Francisco, to require that any reading matter which is printed by a newspaper in return for money, gift or other compensation, shall be marked and branded as advertising. Therefore, I would move that the matter be referred to the Legislative Committee, with the recommendation of this Section that such a bill be prepared for introduction in the various State legislatures, requiring the branding of such advertisements as "ads," and prohibiting their publication as reading notices.

THE CHAIRMAN pro tem.: You stated "recommend," did you not, to the Legislative Committee?

MR. BODEMANN: Yes, sir.

MR. LOWE: I think that to a certain extent we have control of this matter in our own hands. Some of the pharmacists are informing their customers that these are not bona fide reading notices, but are advertisements in disguise—not what they appear to be on the surface, but shrewd catch-pennies. In my neighborhood we have so thrown the weight of our influence against this class of advertising that we are not suffering from so great an invasion of it now as we otherwise would. A lady came into our establishment the other day and asked for a certain article, which she said she had seen highly recommended in the papers. I knew her very well, and commenced to laugh, and told her that what she saw was nothing but an advertisement, and that I could sell her any one of half a dozen other different things which would do her just as much good, and at a very much lower rate. I think if we use the weight of our influence we can in a large measure counteract the effect of this particular class of advertising.

MR. DITTMeyer, of West Virginia: I agree with what Mr. Lowe says. One way I do; I keep the circulars sent out by these houses—for instance, one in Chicago, that makes about six preparations—in which circulars they name the prices to the druggists, and they also make this remark: "The peculiar advertising we are doing will catch the people." I just keep that circular, and whenever any one comes in and asks about these remedies I show him the circular and tell him it is a "fake," and in a majority of cases the customer will take my word, and leave it alone.

MR. E. H. LADISH: That is all very well, but by individual effort you will be as far from obtaining results as you were two or three years ago when brother Hynson drew
up a fine resolution and referred it to the Publication Committee, and there it died. What you want is action. The mere telling of what an individual does in one section of the country, and what is done by another individual two thousand miles away, amounts to nothing. Now if you refer this to the Section on National Education and Legislation, let them see to it that some one gets busy in the various states, and does something. For two or three years we have been talking about these things but haven't done anything, and the thing has become so overwhelming that everybody is kicking. They dismissed the subject two or three years ago very lightly—didn't think much about it. Action is what you want.

Mr. Hynson: I would like to ask if that motion was to send to the Section, or to the Legislative Committee?

Mr. Bodemann: I said to the Legislative Committee. I want to emphasize the truth of what Mr. Ladish said. It reminds me of what my friend Bismarck once said: "You will never make Germany united by resolutions and whereas, because there are too many other 'asses'" (Laughter). "It will take blood and iron." It will take a law, and a strong one, to deal with these people, and private individual effort will not do it.

The Chairman pro tem.: Has anyone else anything to say? While sitting here and listening to this discussion, the thought flashed through my mind—it never having occurred to me before—that in nearly all these preparations there is a large percentage of whiskey, brandy or alcohol, and it might not be a bad idea to have the attention of the National Women's Christian Temperance Union called to that fact: they would probably take action in regard to the matter and might be of assistance to us. I throw this suggestion out, as it just occurred to me. We will first now take a vote on the motion of Mr. Bodemann; that is, to send it to the Legislative Committee.

Mr. Emanuel: Would it not be well to have someone draw up a bill and have it presented to the Legislative Committee, and have that Committee send a copy of it to each branch in the country, with the recommendation that they have it introduced in their State Legislatures?

The Chairman pro tem.: I don't think this Section has that power; we must first present it to the general body for action.

Motion was here voted on and carried.

Mr. Hynson: I move that we request the General Association to instruct the General Secretary to communicate our views in regard to this matter to the National Women's Christian Temperance Union.

Mr. Bodemann: I second the motion.

Carried.

The Chairman pro tem.: We are now ready to proceed to the next portion of the address.

Mr. Bowman: If I had known the attitude of the Association on this question, at the time I incorporated this in my address, I would have left it out; but as I have given much thought to the matter, and have put it in my address, I will read it to you:

"In the East, a new danger has shown forth in the growing strength of the 'chain store' problem, and this has brought forth a suggested remedy that will, as far as the uplifiting of pharmacy goes, surely breed a disease more pernicious than the one it seeks
to cure, for in 'Democratic America' (if you please), no combination exists for long with a clean 'Bill of Health,' where its base rests on the earning power of the dollar, and your syndicate (the American Druggists' Syndicate) working for the eradication of one evil, will surely breed the germ of a pestilence far-reaching and virulent."

MR. HYNSON: I move that the Chairman be empowered to appoint a committee of three to confer with the Committee on President's Address on this same subject.

MR. CHARLES REIFFUS: Would it not be well to get the views of the members of this Association on this particular subject? The motion is to appoint a committee of three to confer with the Committee on President's Address; what is that committee to do—simply to voice their views in the matter or the views of the members assembled here? I think it should be discussed here and the views of the members ascertained, and then send your committee to confer with the Committee on President's Address. If you appoint the committee without first ascertaining the views of the members here, how do we know what they are going to do? Their views may differ entirely with mine and may go there and squelch this whole business—which I hope they will not do. I offer as a substitute motion that we concur in the views of the Chairman of this Section, and that a committee be appointed to confer with the Committee on President's Address on the subject.

MR. HYNSON: I concur in that.

THE CHAIRMAN pro tem.: Gentlemen, the matter is now open for discussion.

MR. W. C. ALFERS: I would like Mr. Bowman to explain why he wrote that—or, in other words, what are the dangers he speaks of—of what do they consist, and why he wants the Association to pass such a resolution; why the necessity exists for it to do so, and particularly in what respect the syndicate he refers to, the A. D. S.—American Druggists' Syndicate—is a danger to pharmacy. I, personally, consider it a blessing, and if I am wrong of course I would like to be set straight about it, and so I would like the gentleman to give us his full views, and his reasons for them—not simply make a vague statement, but his reasons in detail, and proofs, why this syndicate is a danger to American pharmacy.

MR. BOWMAN: First let me explain that as Chairman of the Section I did not ask the Section to endorse my view on the subject. I presented it to you for discussion, as the thought of the Chairman's address. If the Section as a whole sees fit to endorse what I have said, I shall feel greatly honored. The reason I wrote that is simply this: My understanding of the thing is that in the East—and not only in the East but all over the country—a darkening cloud is showing forth in the growth of the so-called 'chain stores,' of a corporation taking over a number of stores and running them, as a whole, with incompetent help, and as a rule paying little attention to scientific pharmacy, foisting upon the people the cheapest materials they can get—not always, understand, but I say in some cases which have come under my observation, at least—to the detriment of the individual pharmacist who strives to serve the people in the best way he can. Now, I am not what you would call an 'eastern man,' and possibly don't look at these things as you gentlemen from Greater New York look at them, but having examined a little, at least, into the plan of the American Druggists' Syndicate, of creating a chain of stores working along the same line, I say simply this, that no combination exists for long with a clean 'bill of health,' where its base rests on the earning power of the dollar. That is to say, that there is no combination that comes together for a semi-philanthropic purpose—for the purpose of eradicating one evil—into which in a short time disease does not creep; and the first thing you know, instead of doing good this combination is a source of evil.
DISCUSSION OF THE CHAIRMAN'S ADDRESS.

Mr. Ladish: Is there a motion before the house? If there is, what is it? I do not recall, exactly.

The Chairman pro tem.: The motion is in reference to appointing a committee of three to confer with the Committee on President's Address.

Mr. Ladish: I don't think this Section ought to appoint a committee of three. I think the committee that has the President's Address in charge, ought to have all this information, however, and it ought to be referred to them. This question is too big to have only a portion of this convention discuss it, and if you do discuss it now you are going to tire some of these people who have settled opinions on it. I therefore, offer as a substitute, if it is in order, that this section of the paper be referred to the Committee on President's Address.

The Chairman pro tem.: Does any one second that?

Mr. W. C. Anderson, Brooklyn: I would like to rise to second that motion, and in doing so I will state that I believe the Chairman, in his address on this subject (while I did not hear all of it, as I was compelled to be away attending a committee meeting) has given the members an entirely different idea of the A. D. S. workings—different from any that organization has ever undertaken, or ever had any idea of undertaking. In the first place, the A. D. S. has never attempted to establish a chain of stores. The proposition to go into such a business was practically voted down at a convention of the stockholders, and consequently, why the A. D. S. should be accused of going into the chain-store business, I can not understand. I have read the reports in most of the pharmaceutical journals in reference to the A. D. S. meetings and the work of the organization, and I have never yet seen one report which placed the A. D. S. in the position of starting one chain of stores. The true position of the A. D. S. in reference to this matter is that it places at the disposal of its members who are threatened by the establishment of chains of stores by the large corporations, the capital of that organization—the goods of that organization—in order that its members may meet the competition. One of the principles of the A. D. S. from the very beginning was to protect the individual retail druggist, to enable him to continue in business on his own account—to keep him from being driven out of the business, as we may say, to give him a living profit on the goods that he sells; and the work that the A. D. S. is doing to-day in reference to combating the chain-store evil, is to select a position where a member is threatened by an opposition store, and back that member in every way possible to keep him in business. I might give an illustration: I have a store in Brooklyn, and am a member of the A. D. S. Suppose the Hegeman Corporation or the Riker Corporation should come to me and offer to purchase my store, and I refused to sell, and they should tell me (as they have told other druggists), "We will establish a store across the street from you," or on the opposite corner, "and we will simply drive you out of business, as you cannot meet our competition." If that condition should exist to-day, I, being a member of the A. D. S., the A. D. S. would put the force of that organization back of me; would give me the benefit of its great buying power, would give me the bottom prices on proprietary remedies, on toilet articles, and so forth, and would put into my store, if I should desire it, a line of goods such as the large corporation handled. If I wanted it, they would supply me with the capital to refurbish my store with new fixtures, so as to make it as attractive as the store across the street that was trying to ruin me. In other words, I would have the full force of that organization back of me, in order to enable me to meet the competition of the chain store that was trying to force me out of existence. That is the true situation as to the A. D. S., and the one thing it has ever attempted to do. We have one store at the
present time, in New York, which was threatened by the chain store—a new store established, with magnificent fixtures, and selling at the very lowest prices, cut rates on everything—and that store is to-day being backed by the A. D. S. For two months after the opposition store was started it looked as if the member would have to go out of existence, but just as soon as the force of the A. D. S. was put back of him, and he was given the advantages of its buying power, he was able to reduce the prices on his goods to the same as charged by the corporation store; the business of this member has gradually increased, and to-day his store stands as one of the first instances of the possibility of a retail druggist being allowed to remain in business and keep his identity, in opposition to the chain store. Now gentlemen, could that man have met the opposition of the corporation stores, and remained in existence if it had not been for the A. D. S. being back of him? I say no; it has been tried time and time again, and the result has been a failure, but in this instance, as we have proven, he has been enabled to keep in business, through the support given to him by the A. D. S., and that is one object of that corporation to-day, with reference to the chain-store evil, to keep the individual druggist running his own store, and prevent him from being driven to the wall by the competition of the large corporation stores. Therefore, I say that before anything is adopted in reference to this matter, there should be a correction made in the information given to this body; it is not fair to the organization, it is not fair to the retail druggist, that a misrepresentation should be made. I do not mean to say that the Chairman has made a misrepresentation intentionally; he has perhaps had some information upon which he has based his remarks, but it was not good information. I do not want to go into the details of the injury done by the chain store; that is too well-known to all of you, and we know that the danger is spreading, not only in Greater New York but throughout the whole country; consequently, I might say to you, as our President said this morning—and he no doubt has given the question very serious thought, or he would not have brought up the matter before the convention—in what other way can we protect the retailer against these chain stores that are driving him out of business? Is there any other proposition? If there is, let us have it. If it is better than the A. D. S., for gracious sake let the retailer have it; we want the retailer to continue in business, and not become a manager or clerk for the Hegeman or Riker Corporation, or the A. D. S.—if it could be turned into a thing of that kind. We are after the elevation of the retail druggist, and if we have no better means of protecting him let us take advantage of what we have at the present time, and not attempt to condemn it.

The Chairman pro tem.: Before we enter into any further discussion of this motion, I wish to call attention to a portion of the address which has been lost sight of, and which is the vital part of all this. The Chairman states: "In the East, a new danger has shown forth in the growing strength of the chain-store problem, and this has brought forth a suggested remedy that will, as far as the uplifting of Pharmacy goes", &c. That is the principle he alludes to, "as far as the uplifting of Pharmacy goes". He says this has this tendency. Now in all this discussion there has not been a word said contrary to this part here; that is the part he wishes you to concur in; that is the milk in the cocoanut.

Mr. Bowman: The Chairman tried to make that sentence the basis of the whole thing.

Mr. Anderson: I would like to ask what the Chairman means by the "uplifting of Pharmacy". I do not believe there are any pharmacists here not in favor of that. If we are not here for that, we would not be members of the American Pharmaceutical Association; but while we are all in favor of the "uplifting of Pharmacy," we all realize it is impossible for us to keep it uplifted unless we have something in our pockets to keep us going.
MR. BOWMAN: I have never been able to see how pharmacy could be uplifted by meeting clean-cut, close competition on proprietary remedies and toilet articles. That is good commercialism, I admit, but, gentlemen, is it true pharmacy?

MR. ALPERS: In reference to this last remark, that pharmacy cannot be uplifted by meeting keen competition from which we cannot escape. then the only thing that can be done by one of these unhappy individuals who has one of the big stores established in his neighborhood, is to go to the poor house and uplift pharmacy in that way. Is that his opinion? What does he propose to do if one of these chain stores should be located across the street from him? Will he tell us how he is going to uplift pharmacy under those conditions—except to meet the competition and show these large stores that they are not almighty, and that there is a combination among the druggists that can fight them; and if the druggists act harmoniously and through the agency of their organization help the unhappy member who is in danger of being crushed out by the competition of the chain stores, will not the establishing of these chain stores soon be stopped? No matter whether we uplift pharmacy in that one instance, or not, we don't pull it down; we help a member in distress; it is the one thing in that case we can do—help him by every means we have to help him, and then we can speak of the uplifting question, but as long as we sit idly by and allow these large corporations to crush out the individual retailers, one after the other, where does the "uplifting of pharmacy" come in? It is a phrase used here to attack a beneficial organization; it is a vague phrase that in this instance means absolutely nothing. We have the means to fight these large corporations when they try to crush us out, and let us take advantage of it; or if you have any better plan, let us know it. Tell us what you would do in such a case, if one of these large corporation stores was to be located along side of yours, or across the street from you! Where would you go for assistance—and let the others come and tell us.

MR. PRITCHARD: What we want to arrive at is, what, in the Chairman's opinion, is the best plan, or what does he propose, to prevent this outside power from causing depression in pharmacy? Now the only thing offered so far has been a plan by which a certain fund shall be created, which a pharmacist who desires to remain a pharmacist, can depend upon for aid in his fight to preserve his business which he has been able to build up only after years of struggle. There has been no plan proposed that would prevent such a man from being crushed out, other than what has been explained in our hearing by Dr. Anderson. I am in a position that I am thoroughly independent of every retailer, wholesaler, buying club, or anything else. After having conducted my own drugstore for twenty-eight years I am now outside of the retail drug business and am looked upon as a consulting engineer. My opinion is that under present conditions a man who has a good drugstore, established in a good location, and is threatened by the coming of a chain store into the same neighborhood with being crushed out of business, has no place in God's world to go to for help. Now the paper read this afternoon by the Chairman of this Section is an illustration of the danger of a little learning. I say this without meaning to be at all offensive. The Chairman has a little learning in regard to chain stores, and a very much smaller amount of learning in regard to the proposed efforts adopted by the A. D. S. Now the A. D. S. method is to put a fund where it can be had for the use of the retail druggist who is threatened with being crushed out. That don't mean, necessarily, that another store must be established to crush out the proposed new store; it only means that the fellow who proposes to invade a certain territory to crush out the retailer who already occupies it will not do so if he knows there is an immense fund which can be drawn upon for assistance, by the victim who has been spotted by the chain stores. If this Association has something better to offer
than what the A. D. S. offers, let us have it; but unless you have something practicable to suggest, don’t come here with papers telling us to drive that thing away, which is the only thing we now have to assist us in our fight against this competition, but help us to build it up.

Mr. Rehfuss: Mr. Chairman, I have listened with a great deal of interest to what Dr. Anderson has said. I think it is the first time I have heard a clean-cut statement of what the A. D. S. proposed to do with regard to the chain-store proposition. I think the Chairman of this Section, like myself, has probably been led away by the newspaper accounts of what the American Druggists’ Syndicate would do with regard to chain stores. I know my impression has been all along that the A. D. S. proposed to start stores where they found retailers who were not in sympathy with their movement. That has been the impression that has been gained by a great many pharmacists throughout this country; it has been the impression I have always had. I have nothing against the A. D. S. and never have had; no one has ever heard me say one word in criticism of it; they have their mission to fill and are justified in their existence, and no doubt they are a great benefit to retail druggists. To me they have been of no use; but I say I am very glad Dr. Anderson has made this clean-cut statement of just what their position is with regard to chain stores. It is the first I have heard of it, and I know there are others here who have not gotten the information in the same light Dr. Anderson has given it to us.

The Chairman pro tem.: If I might interrogate the Chairman, I would like to know—you do not object to certain activities of the A. D. S.; it is only along the line of interfering with the uplifting of pharmacy.

Mr. Bowman: That is the only thing I object to, and the only reason I touched upon it in my address was that I hoped to bring out information such as has been brought out. I hoped to find out what the attitude of the members of this Association was with regard to work of that kind. I hardly hoped to have as concise a statement of the intentions of the A. D. S. as we have had, but my object was to bring out information on the subject which the Association would not have had otherwise, and I feel more than repaid. I do not object at all to the work of the A. D. S. along certain lines. I still think that as far as the uplifting of pharmacy goes, the fighting of the chain stores by competition, even as the gentleman says the A. D. S. proposes, has not helped it. That is simply my individual opinion. If you do not agree with me, I cannot help it. I did not expect you would. I am glad the discussion has brought out the points it has, and I am glad we know the attitude of the A. D. S. in regard to the matter.

Mr. C. M. Ford: I would like to suggest that we find some way of stopping this useless talk. There was a committee appointed by the general session to work on this same thing, and I don’t see why this body should take up for consideration the affairs of an organization like the A. D. S. any more than they should the affairs of any other organization. As to the quality of their goods, you might get information by going to individuals here, but no one is going to rise here and tell you, even if you ask. Dr. Anderson has given us a very pretty figure of the A. D. S. and what it has promised to do, and he has said something of what it has done. His picture is right in every particular, except that it is not true, and as far as the A. D. S. saying they are not in the chain-store business, they have made the threat. You can go around and ask individuals here whether their word is good. I am a member of the A. D. S. and one of the oldest; I got my stock for nothing, or nearly nothing, and am willing to sell it at the market price (laughter). If he thinks the quality of their goods is equal to some other houses, then let him put them on his shelves. We do not think so; it is doing us a lot
of harm. But I do not think it is the business of this Association to take up the quality of their goods, and I am sorry the Chairman of this Section has taken up the matter. I should as soon think of attacking Parke, Davis & Co. or some other concern, and bringing them before this body for trial. They are not on trial here, and you would not think of bringing them here and putting them on trial before this Association, for any such thing.

Mr. Anderson: I do not think the remarks of the gentleman call for much answer—except one assertion as to what I had to say as to the plans of the A. D. S. being not true. The gentleman is entirely in error in making that statement, and I think he will be glad to retract it.

Mr. Ford: No; I said the picture you drew of what they would do for a man in Brooklyn—and Brooklyn is just a small part of this great country (in fact I have not seen it but once in a lifetime; at the distance we are we can not take much interest in the affairs of a little city like Brooklyn—I say the picture you drew is not true because it is not real, and I do not believe it will ever be realized by the A. D. S. under its present organization.

Mr. Anderson: Of course we can not say what the future will bring forth. I explained that the A. D. S. was trying to do this thing, and so far as undertaken it was successful. The gentleman says he don't want to put any concern on trial here as to its products; at the same time he attempts to condemn the A. D. S. products.

The Chairman pro tem: Will Mr. Ladish please repeat his motion?

Mr. Ladish: My motion is that this portion of the Chairman's address be referred to the Committee on President's Address, for their information.

Mr. Pritchard: I move you that this paper be referred to the Publication Committee, and in doing that I concur in the views of the gentleman from Colorado when he said that this Association has absolutely nothing to do with the A. D. S. If the A. D. S. is in position to help the retail druggists, I think it will make it known to them, and just why the American Pharmaceutical Association should take up the work of the A. D. S., I cannot conceive. The A. D. S. is a private corporation, and, as I said awhile ago, it has the right to exist, and I have no objection to it; but I do object to this Association, or any other Association, taking up the work of the A. D. S. I think this paper should be referred to the Committee on Publication, and I make that as a substitute motion.

Mr. Yeomans: I would like to move, as a substitute for the substitute, that a transcript of the shorthand report of these proceedings be also referred with this address, which is to be referred to the Publication Committee, in order to correct some of the mis-statements that are made in this address.

Mr. Kiler: I second the motion.

Carried.

The Chairman pro tem: We are now ready to take up the next section of the address.

Mr. Bowman: The next thing I spoke of was the question of Labor. That was simply a general statement. I say; then:

"The increased cost and scarcity of a largely increasing number of our native drugs brings us face to face with a fact that we persistently ignore; that if we are to continue the use of our native drugs we can not much longer draw on lavish Nature alone, but
must aid and abet her in the conservation of her resources, and must take up the cultivation of a number of our native drugs for commercial purposes. We must remember that this is not the work of a day, nor a year, possibly the working-out on a basis of commercial profit is not the work of a lifetime, but looking forward into the future the need becomes more apparent, and I would suggest that this section appoint a committee to look into the subject and gather such information as may be obtainable, reporting same to the Association. This will open up a most interesting field of work, and the subject becomes so virile that it would be well worth the while of the Association to take some steps toward the giving-out of information in detail on the possibilities of the cultivation of certain native drug plants for commercial purposes. I am well aware that the Department of Agriculture is working along these lines, but there need be no conflict of interest."

My object in saying that was simply this: I think you will all agree with me that we, as retail pharmacists, at least, do not fully appreciate and co-operate with the Department of Agriculture in its plant-investigation work. We, as users of certain native drugs, have seen the price go up and go up, and go up, until it became prohibitive. I think the manufacturer will agree with me that the difficulty in obtaining supplies of first quality domestic drugs is becoming greater and greater; and its simply occurred to me that if this Association, through a committee, should make some effort to gather all the data it possibly could on the possibility of plant cultivation, and that the Association should take some means of disseminating this to the general public, that it might in the end, possibly in one or two decades, work out to the commercial advantage of the manufacturer, and the retailer as well.

Mr. C. B. Lowe: I think if the Chairman had looked into this matter more thoroughly, he would have found that the Government is doing a great deal at this time. They are cultivating a number of different seeds. Of course we know ginseng is being cultivated quite extensively now, and it is becoming a matter of profit to those who sell the seeds, at the prices at which they sell them, and I think possibly some of the cultivators of this root make considerable money. We could stand with complacency the extinction of ginseng, because it has no place in American pharmacy. On the other hand, hydrastis is an important product, and I understand the Government is devoting its energies toward the propagation of this plant, and it is possible that we will in a short time be growing it in this country.

Mr. Bowman: The only object I had was to stimulate interest in the Association in this work.

Mr. Rehfuss: I think the point of the Chairman is well taken. As Professor Lowe pointed out, the Government is doing extensive work along this line now, and is trying to get all the literature on the subject it can. I, myself, did some work in this line some years ago, when I was occupied by botany more than I am now. I received a letter from the Government asking me to send in all the papers I had written on this subject; and I know another man—Professor Lloyd—who has worked extensively in this direction. It is a subject that is well worth considering, and I believe the endorsement of the Association of the work of the Government can certainly do no harm. At this time a great many medicinal plants are being cultivated, or experimented with. They are trying to cultivate senna in California; and as has been pointed out, it would be well to cultivate hydrastis. I believe the time will come when nearly every plant of the pharmaceutical field will be grown in this country. A company has been formed in New York for cultivating the camphor tree in America, and they expect in a few years to have native camphor in the market. I make the motion that this part of the Chairman's address be endorsed.
DISCUSSION OF THE CHAIRMAN'S ADDRESS.

Mr. Lowe: Before action is taken, I would like Mr. Kebler to have ten or fifteen minutes in which to tell us what the government is doing along this line. I think it would be very interesting information to the Section to hear it.

The Chairman pro tem.: I am sure we will all be glad to hear from Mr. Kebler.

Mr. Kebler: Mr. Chairman, while I know of the work being done in the Department of Agriculture, and am quite well versed in its various details, it comes to me second-hand. Dr. True, of the Bureau of Plant Industry, has charge of that work. They have experimented to a large extent, by the way of growing poppy, for the production of opium in the United States, and while they have been successful in producing opium which assayed fairly well, Mr. Richtmann knows more about that than I do, because he had that particular line under consideration when he was in Washington. They even produce morphine by treating the crushed plant itself. I was talking to the Secretary just the other day, and he referred to that feature. The only trouble appears to be to get the labor to produce the commodity. The capsules are simply gathered by a machine, or otherwise, and crushed, and the morphine removed in that manner, so as to eliminate going through the process of producing the opium itself. It is well known that there is so much more morphine used than opium, unfortunately, that that is a very important feature. Then they have grown large quantities of digitalis, and by the way, I am of the opinion that by proper investigation you will find that this country produces all the digitalis we want.

Last summer, when I was passing through the western portion of Oregon, I saw plants six, eight and ten feet high, with the nicest kind of leaves you could possibly imagine. We looked the situation over, and believe from the information we gathered there, that there is plenty of digitalis grown in the United States wild, to supply almost the entire demands of this country. I want to qualify this statement simply by saying that so far as I know, the article has not been tested with reference to its physiological activity, but Professor Hale, of Cincinnati, thinks that it is as active as that imported; consequently, I see no reason why the article grown in Oregon should not be as valuable as the article imported.

They have also grown considerable quantities of henbane leaves. Stramonium we need not speak of, as that is so common you can find it on every field of refuse.

Mr. Lowe: How about hydrastis?

Mr. Kebler: The Department has done some work on hydrastis, but the work of Lloyd, so far as the records go in this country, surpasses that of any one else. I have never been out to his farm where he grows hydrastis, but he tells me that he has any quantity of hydrastis for immediate use for the United States. He does not have to rely on the market, and he has a very simple method of propagation. The growing of medicinal plants in the United States appears to depend on this one point, namely, obtaining labor at a reasonable price. First, labor at a reasonable price, and second, obtaining a price per acre of land cultivated equal to that of any other commodity grown. For example, if a farmer can grow 40 bushels of wheat to the acre, and get $40 for it, deriving a certain profit, he expects that land to produce as much profit, with the same amount of labor, planted in some other commodity; and those are the two propositions we must overcome in the United States before drugs can be successfully grown, namely, cheap labor, and the possibility of producing for the owner of the land equally as great a return as he can obtain by growing any other regular farm commodity.

The Chairman pro tem.: We are now ready to vote on the motion. Do we all understand the motion? Will the gentleman offering the motion kindly repeat it?
Mr. Rehfuss: I made a motion that this part of the Chairman's address be endorsed by this Section.

The motion was then put and carried.

Mr. Bowman: The balance of the address being of no special interest, we will dispense with the further consideration of it and take up the next number on the program.

(Mr. Bowman here resumed the Chair.)

The Chairman: The first paper is entitled "The Chemical Laboratory as a Side Line," by the Secretary, George H. P. Lichthardt, of Sacramento. Inasmuch as Mr. Lichthardt is not here, and the paper is short, I will ask Mr. Seltzer, of Detroit, to read it.

THE CHEMICAL LABORATORY AS A SIDE-LINE.

BY G. P. LICHTHARDT, SACRAMENTO, CAL.

Often our attention has been directed to the various side-lines sold by the druggist for the purpose of adding to the small sum returned by his profession as a recompense for the sixteen hours of daily toil that seems to be necessary to conduct the usual bureau of public comfort known as a drug-store. We have had about everything from crockery and wall paper to shoe-polish and auto supplies; and, in fact, a writer in a paper some time since stated that, to be a successful druggist, one must be prepared to furnish everything likely to be asked for, and that while the prescription department was important, it was by no means the greater part of the drug business.

Now friends, I have a side-line that has paid well and has given good return for the investment. Some thirteen years ago when our present store was opened I made up my mind that by establishing an analytical laboratory a good source of revenue could be added; I went to the various physicians with whom I had an acquaintance and stated just what was proposed to be done. They were told that a laboratory for chemical and bacteriological work would be at their service and that I wanted the sputum work and urine-analysis, but alas, it must be said that the outlook was very poor for it was about five years before the first paying job was presented although plenty of charity work was done; but by keeping up with the advance of chemistry the physicians soon came to understand that here was a place where information on most any chemical subject could be obtained. To-day we have about $2000 invested in this laboratory and the money is well invested.

The general public is responsible for the fact that medical men hold themselves superior to the pharmacist in knowledge pertaining to chemistry and allied sciences; for they side in with the physicians on all questions involving these subjects, not taking in consideration the fact that most medical men know little or nothing of these subjects. In building up a laboratory practice the pharmacist must overcome this prejudice
against him and his work. I remember during a controversy regarding a
cwater-supply several years ago, when some of the doctors advocated the
use of a certain well, I saw a chance and went into the fray with the result
that one physician, an old school-mate of mine, came and said that it was
ridiculous for me to make statements on such a subject as I had not gradu-
ated from a medical college and therefore knew nothing about the sci-
ences. A few months afterward this same dear doctor rushed into my
place and said, "Can you apply a test for strychnine immediately"? He
was told that I certainly could and a box of powders was produced which
upon examination proved to contain the poisonous alkaloid of nux vomica:
these powders had been dispensed for calomel triturates. This physician
now respects the attainments of at least one pill-roller.

Our work has made us known not only to the medical profession but
to the laity as well, having proven to be the best advertising medium we
can get. Interest has been taken in every municipal improvement in city,
county, and state government and having done more or less chemical
work for these branches of government the newspapers have brought the
name of Lichhardt before the public many times.

In March of this year a bond election was held in Sacramento for the
purpose of erecting a public filtration plant. This gave a great opportunity
as the papers published many articles written by myself, and one gave me
a half page with headlines in large type "Lichhardt Says"; I also gave
lectures on filtration and performed experiments in all of the public
schools.

This question of side-lines, I think, has been solved satisfactorily in my
case; but as has been said before it is a case of keeping everlastingly at it,
and such work cannot be built up in a day.

The paper being read, it was, on motion, duly seconded, referred to the
Publication Committee.

The Chairman: We will next listen to a paper on "The Telephone Question," by
Wilhelm Bodemann, of Chicago.

Mr. Bodeman here read his paper.

THE TELEPHONE QUESTION.

BY WILHELM BODEMANN.

Why is it that after the retail druggists in our larger cities have demon-
strated by years of experience that the telephone in their stores can be
made a splendid money maker, turning expense into revenue and giving
them a first-class service, that in hundreds of other cities the druggists do
not fall in line and emancipate themselves from the old free lunch nuisance
telephone? The success of this movement has been so thoroughly demon-
strated it would seem as if every druggist in the United States tomorrow
would want to get into the band wagon and make a profit instead of a loss
out of his telephone. They are doing this slowly, to be sure, but after all these years of experience it would seem as if all should join.

Wherever the slot telephone has been introduced it has been found a winner from the start. Pessimists in large cities, generally the larger downtown stores, have at first feared that the slot pay telephone would prove injurious. The reverse has been the result in most cities, where these large downtown stores overcame their fears we can show you by figures that some of them pay a good part of their high rent by these pay telephones, and, as you all know, figures don't lie. By figures I can demonstrate that these large downtown stores have their own telephone free of expense, always open for inpouring orders, and clear a heavy share of the rent to boot. It does not require legal evidence to prove the fact that a man who has business to transact over the telephone values his time more than the expenditure of a nickel, hence talks condensed—shorthand as it were—while a free-luncher who telephones because the telephone is free, has time to burn, and knocks your own telephone out of business for business. The telephone companies are willing to establish pay telephones, the public is willing to pay for telephone service, why should the druggists stand back and let their chance to reap a harvest go to waste by refusing to introduce pay telephones? The great N. A. R. D. has made the introduction of pay telephones an issue, and this issue has brought results in the increased membership in every city where pay telephones have been established. I assert that the great A. Ph. A., standing as it does for all that is "Good and Pure" and in the line of uplift movements, should add the introduction of pay telephones to its strongest arms of activities. I use the phrase "Good and Pure" advisedly. I need not go into a long argument, because I dislike long-winded harangues, to prove to you, my brethren of the A. Ph. A., that I deprecate profanity, and on that account I advocate slot telephones, simply for their purifying remedial properties. With the old-line telephones I have heard more sulphurous invocations in pharmacies than can ever be expected in Dante's Inferno. Introduce fireproof, soundproof booths with the pay telephones, and the service becomes at once so admirable that the drug-store atmosphere changes to the environments of one of the Moody and Sankey revival meetings. I would therefore strongly advise the establishment of a Standing Committee of your Section, devoting its energies to the promotion of pay telephones.

I wish I could have been briefer, but my time is limited, and I recommend a discussion of this subject to your good graces.

I attach as a sample of my method of going at it—a letter addressed to Kansas City Druggists which I wish to make a part of this paper.

To the Kansas City Druggists:

If I were in the place of the Kansas City druggists I would do one of three things:

First. I would induce the Home Telephone Company to install slot phones, for reasons explained in this letter.
Second. If the Home Company refused to install slot phones, put the Home phone in a part of the room where it is not accessible to the public.

Third. Should the Home Telephone Company decline to remove the phones to back room, or refuse to install slot phones, do away with the unprofitable phone altogether for following reasons:

Nothing better illustrates the fact that experience is the greatest teacher than the evolution of the drug store telephone. There are few cities of any size in which the druggist has not been able to find out that if he has a slot machine telephone he gets good service for himself and for the public, and that he as well puts into his pocket a substantial return of the service rendered. The old practice was bad service for everybody and an annual rental paid out by the druggist. In some few places this practice still remains that the telephone of one company has a slot machine and the telephone of the other company is free, i.e., it is free to the public but not free to the druggist, because he pays for it.

Some who have not investigated the practice elsewhere seem to think they would lose business if they do away with this free telephone. It has been demonstrated again and again that this is not the case. The drug store is the natural public telephone station and the public is willing to pay for good accommodations and good service. No one ever thanked us for the privilege of standing in line behind our hard-worked telephones while the free-lunch fiends gradually got out of the way one by one. In fact, all we got was the reverse of thanks.

Druggists who have two telephones and are operating both with slot machines are not only giving the public better accommodation, for which they get thanks and pay, but they are getting good telephone service for themselves and proper pay for the space afforded and services rendered. This is no experiment, but the experience of years has shown that there is every reason for emancipating the drug store telephone from the free-lunch rut. There is not one good reason for going ahead in the old way. It is in the hands of the druggists to accomplish this themselves.

The Telephone Committee of the N. A. R. D. has been preaching this for years. One by one the big cities have fallen in line and telephones represent a big profit to the drug interests instead of a big expense. Hundreds of delegates to our conventions have testified to this. Thousands in the trade all over the country are daily testifying to it by their use. Generally our trade is not backward in protecting itself against loss or imposition, especially where no good comes from it. Why there can be any substantial number who prefer to pay out their good money for telephone service, which they themselves make bad by attempting to give it away, is one of the things which seems past finding out.

Yours for profit and comfort,

W. BODEMANN,
Chairman N. A. R. D. Telephone Committee.

THE CHAIRMAN: The paper is before you. Is there any discussion?

MR. LOWE: I think it might be interesting to have Mr. Rehfuss, of the P. A. R. D. Committee, tell us about that.

MR. REHFUSS: The telephone question is one that the P. A. R. D. has been interested in for years. I think we were one of the first Associations, next to Chicago, to take up the telephone question with the telephone companies. Prior to that time we were only receiving a commission of 10 per cent., but after some little agitation on the part of the members of the Association, and work with the telephone company, we succeeded in getting that commission up to a point where it now pays 33 1/3 per cent., after a certain guarantee has been made to the telephone company. In other words, we have a guar-
M. R. Rehfuss: I would like to say, though, that these beneficent results have been accomplished by united effort; it could not have been done by an individual working by himself. The department stores and the drugstores are the only stores having these slot telephones. They will not put them in other stores. A neighbor of mine had a telephone that the public used very much, and he got disgruntled over it, and wanted the telephone company to put in a slot 'phone, which they would not do. He said if they would not, he would have his taken out, which he did; but he suffered for the want of a 'phone; and it was only through the efforts of the P. A. R. D. that the present satisfactory condition was brought about.

Mr. Alpers: Well, I am from New York, and will have to admit that in this one case Philadelphia is much faster than New York. In New York we have had a slot machine for years, but our commission is much smaller than what the gentleman from Philadelphia states it is there. We get only 20 per cent. commission, and there is now a movement on foot by the telephone people to reduce our commission to 10 per cent. It was my intention before I came here, to organize in New York a strict opposition to this reduction, because it will not pay us to keep the machines in our stores on a commission of 10 per cent. I have in my store four booths for these slot machines, and as I figure it, the rental of that much space is almost equal to the returns, and that is the business way to look at it. Now if the commission is cut down to 10 per cent., I will be suffering a loss by giving up this space to the telephone booths. I want all the information I can get as to the commission being allowed in other cities, because there will be a big fight on in New York over this matter. They want to reduce the commission to one-half a cent on each call. I had in my store last winter an average of 160 calls a day, and reducing that by one-half will amount to quite a little sum in the course of a year. I am not going to give it up without a fight, and I hope the druggists in New York will look at it in the same way.

Mr. Rehfuss: That is an illustration of the value of organization. I venture to say that the telephone companies that are operating in Philadelphia would not dare to lower
the commission to the retail druggists, because if they did, I believe the drug trade, or at least 75 per cent. of them, would say "Take your telephones and get out, we will not have anything to do with them."

Mr. Apple: I concur in what Mr. Rehfuss has said. We feel very secure in Philadelphia, for the reason that we have demonstrated to the corporations what we can do— that we will stick together, and when we make demands which are just demands, we will get them.

Mr. Bodemann: What Mr. Rehfuss says is absolutely the truth. Co-operation does the work. As far as the telephone companies in Chicago are concerned, some of the 'phones there are also 'phones of the American Telephone & Telegraph Company—the so-called Bell Company. Before I left I was assured by these offices that they would take up the question of New York with the New York office, and see if they could not better, instead of reduce the commissions there. To the New York druggists I will say that I am sorry that as often as I have written down there to get information as to the conditions in that city, I have never received an answer—never once—but if they will put up a solid front they may rest assured that the telephone company will back down. As far as the profits in Chicago are concerned—Dr. Alpers said he did not receive very much more than the space the 'phones occupied cost him in rental. There are stores down town in Chicago that receive over $3,000 a year net income from the telephones. If that is not enough rent for the booths, I would like to know how much more rent is wanted.

Mr. Alfers: It depends upon the rent they pay for the store.

Mr. C. Meyer: I would like to state that the telephone situation in Baltimore is very satisfactory. A few years since an independent company started up, and the Bell Telephone Company at once began to take notice. The retail association there, in co-operation with the Washington association, went to the Baltimore office and said that unless they were paid a commission of 25%, the telephones would be all taken out. We put up a " bluff" and said 25 per cent., although we only expected 10 per cent. The company agreed to pay 15 per cent.; and about six-months since the independent company was absorbed by the Bell Company. Notwithstanding that, six or eight weeks ago we were informed that they had a meeting and it was decided that after the first of June they would increase the commission to 20 per cent. We did not have to give any guarantee—and refused all offers of the company except a straight commission. In this way we wanted to protect the druggist who only has a few calls; we wanted him to have the benefit, as well as the druggist in the down town section.

The Chairman: Is there any further discussion of the paper?

Mr. Yeomans: Last year the earnings of the druggists of Chicago from this source amounted to over $145,000, and that was not "stage money," either; it was real money. I have two small stores, not exactly suburban, but away from the center of the city, in which the 'phones are earning pretty close to $1,000 net, and doing a little better and better every month. We take pains to "boost" the telephone business as far as we can; it is a very profitable thing.

Mr. Bodemann: My motion is that this Section recommend to the branches of the A. Ph. A. that they appoint committees to deal with the telephone situation.

Mr. Apple: Can we recommend to the branches direct? Should not the recommendation come from the general body?
MINUTES OF THE SECTION ON COMMERCIAL INTERESTS.

Mr. Alpers: The recommendation should come from the general body; coming from the Commercial Section, which represents only a part of the Association, it would not have as much weight as if it were to come from the general body.

The Chairman: Will Mr. Bodemann amend his motion to that extent?

Mr. Bodemann: Certainly I will.

The motion as amended was then put and carried.

The Chairman: We will now proceed to the next paper, "The Commercial Advantages of Conducting a Drug Store Exclusive of Side Lines," by Mr. W. J. Frazier, of Wichita, Kansas.

In the absence of the author, the paper was read by Mr. Noll as follows:

THE COMMERCIAL ADVANTAGES OF CONDUCTING A DRUG STORE EXCLUSIVE OF SIDE LINES.

BY J. W. FRAZIER, WICHITA, KANSAS.

The cherished hope that I may clearly set forth in this paper, in words inoffensive and helpful to my fellow-workers of the pharmaceutical profession, a profession which means so much to every one of us and one in which to succeed should be loved so much that all our energies should be given to it, is the reason I have selected the above subject, to which I most humbly invite the attention and careful thought of this Association.

In my humble opinion the druggists of to-day are tending too much towards scattering their energy and dividing their time with side lines to the everlasting detriment and neglect of their high calling. A calling which for its importance and the essential part it plays in the preservation of the health and happiness of the people should be uppermost in the hearts of all her loyal devotees.

The average druggist of this country does a great deal of the detail work of his own store, not having a sufficient volume of business to justify hiring competent help to do it for him. This being the case, a large part of his time is given to selling post cards, wall paper, soda water, ham sandwiches, oyster stews, etc.; if he permits his store to become an emporium for all these lines as so many do, they will naturally become such an important part of his business that he is liable to grow into a greater dependance on them and think they are more vital and important for his financial success than drugs and he gives them the preference, thereby gradually losing his drug business as well as his love for, or interest in the same. It has been said by Him who "spake as never man spake," that no man can serve two masters; he will either love the one and hate the other or he will cling to the one and despise the other.

It is true these side lines do not require the mental exertion that close application to our profession does, and we say neither are they so remunerative as is the practice of pharmacy, even in its most limited professional sense.
The patent medicine business which has been forced upon the druggists of the country has, we admit, done much to increase the dropping of the dollars into his till, but we unhesitatingly assert, without fear of successful contradiction, that we and the community at large would be better off without them. We because of increased profits and higher ideals and the public because of increased profits and generally better health. To my mind the druggist could not do a more unprofessional or non-ethical thing than to coöperate with a patent medicine manufacturer in guaranteeing it to the consumer, to do the work or money refunded by the druggist; for in so doing he becomes a monstrous quack and is a stench in the minds of the medical profession, if they take time to notice him at all. The remedy for this is to refuse absolutely to guarantee any patent medicine for any one, for we know not what we do, neither can we know, for the makers keep the contents of their remedies a profound secret. If, however, the facts were known we would, in all probability, in most cases find that their principal virtues lay in the stories or talking points they have manufactured with which to sell their products, which they claim to have been discovered by a lone Indian in the jungles of his haunts, a Chinaman, when trying to accomplish some superhuman act, or a gypsy witch, while trying to extricate herself from the cauldron into which went the fingers of her birth-strangled babe.

The claim made by certain manufacturers of patents or proprietaries, professing to be a syndicate of retail druggists who have culled the best formulas from numerous physicians' prescriptions and made them into proprietaries, and are successfully placing them on the market, guaranteeing them to cure or money refunded, is, in the judgment of the writer, unfair to the pharmaceutical as well as the medical profession, and should be strenuously condemned by both professions.

It has been our observation that if the pharmacist tries as best he can to treat the physician with ethical courtesy, devoting his time and attention strictly to his own profession and leaving side-lines to those to whom they belong, he will soon have all he can do in the way of strictly drug business, and the public will learn to look upon him as a professional gentleman instead of a grapper after everything in sight; and that he would have an opportunity to become better posted because of his wider experience in his own line of business goes without saying. The physician must respect him if he maintains his professional dignity and a friendly, ethical attitude toward the profession.

This leads us to say, we do not believe the average druggist realizes the full importance of his calling. If he did he would find plenty of interesting and profitable employment for all his time in the practice of pharmacy, and welcome would be the condition brought about in his store where thorough sympathetic co-operation between patient, physician and pharmacist obtained.
In closing, let us say that our admonition to all who love their profession is: Devote all your time and attention to it, leave the side-lines which are foreign to the business of the pharmacist, to those to whom they of right belong, and in your advertising speak the truth, the whole truth and nothing but the truth. Keep busy at your work, maintain your dignity by being ethical, courteous and professional at all times, and your future success and happiness is assured.

The Chairman: Is there any discussion on this paper? If not, we will entertain a motion to refer this paper and the preceding paper to the Committee on Publication.

Mr. Apple: I make a motion to that effect.

Motion seconded and carried.

The Chairman: The next papers are: "The Commercial Growing of Eucalyptus for Oil," by Edw. J. Binz, of Los Angeles, Cal.; and "Early Closing," by Robert A. Leet, of Oakland, Cal. The authors not being present, these papers will be read by title only, and we will now listen to a paper by Mr. Lyman F. Kebler, of Washington.

Mr. Kebler here read his paper as follows:

A PRACTICAL ASPECT OF STANDARDS.

By L. F. KEBLER.

It has been my duty for the past fifteen years to pass judgment on medicinal agents of various forms, first as analytical and manufacturing chemist of a pharmaceutical manufacturing house and later as Chief of the Drug Division of the Bureau of Chemistry, and during this time I have had many internal struggles with myself between the goods as actually met with in commerce and the prescribed standards which are in many instances ideal but often impracticable. This condition can of course never be completely rectified but I am sure it can be materially improved upon. Some of the academic standards, as they are called by the trade, have been enacted into law and the responsibilities and difficulties have at the same time been accentuated. The above remarks are applicable more particularly to plant drugs, whole and powdered. In order to clearly set forth the situation I shall cite a number of concrete representative examples.

The United States Pharmacopoeia, 8th Revision, designates buchu as "The dried leaves of Barosma betulina" which statement is followed by a description of ideal leaves. It is a well-known fact that the article in commerce always contains greater or smaller quantities of foreign material, such as stems, twigs, old worthless leaves, etc., derived from the plant from which the leaves are gathered. These substances are incidentally introduced at the time of collection. The medicinal value of the leaves is naturally reduced or modified in proportion to the amount of this foreign material present. The problem is still further complicated
by the gathering simultaneously of other species of buchu leaves similar to the official leaf and occasionally a few entirely unrelated leaves are found. It will be noted that the impurities referred to above are either approximately inert or possess medicinal properties similar to the official leaf itself. No provision is made by the legal standard for the presence of any of these foreign substances, yet it is impossible to meet with a trade sample absolutely free from contamination of the above character, and the question naturally arises how literally shall the standard be interpreted. This is a problem we are confronted with almost daily in our work and those who are conversant with the situation, can readily understand the difficulties. The Food and Drugs Act is a criminal statute and the courts construe such laws literally. If the position should be taken that all buchu leaves must literally conform with the standard laid down in the Pharmacopoeia, the supply would be reduced to a very low ebb indeed and the price enhanced to a prohibitive basis. A rigid adherence to the standard is manifestly impossible. In such an event importers, dealers and manufacturers would be up in arms and properly so. The next question confronting us is: How much of these foreign substances indicated above, should be permitted? Shall it be five per cent., ten per cent., more or less? We must of course be guided by the nature of the impurities to a certain extent and for that reason no definite upper limit of the foreign material of the character indicated has been set. A tentative upper limit of ten per cent. has served as a guide. It is believed that the Pharmacopoeia should introduce a definite maximum upper limit of impurities of this character, thus giving the trade a working basis and at the same time remove the onus, censure and criticism from the individual. The chief objection to fixing an upper limit in cases of this character is the fact that certain producers and dealers instead of making an effort to reduce the amount of foreign matter to a minimum, make a studied effort to leave present the maximum amount of such material permissible.

Let us now turn our attention to cubeb berries, another crude drug recognized by the Pharmacopoeia. The standard requires this product to consist of “The dried unripe, but fully grown, fruit of Piper Cubeba,” which is followed by a definite description of the size and character of the fruit. By careful study of this standard any one familiar with trade conditions can readily see that it is vulnerable in several particular points. For example, it limits the character of the fruit to the unripe but fully grown product. In the second place, no provision is made for any foreign material, such as stems, twigs, etc., naturally introduced during collection. It is well known that almost all consignments contain fruit which is neither fully grown nor sound in every particular. The question confronting us is here again: Shall the standard laid down in the Pharmacopoeia be adhered to strictly, and if not, what latitude is permissible? Would it be safe to permit the presence of five per cent. or ten per cent. of the sum total of
fully matured berries, undeveloped berries, stems or twigs? Could such a product be safely used in preparing the various medicinal agents of which cubeb berries represent the sole constituent or a material part? In some instances the amount of foreign material comes well within the five-per-cent. limit, but in other instances it exceeds even fifteen per cent. A tentative upper limit of ten per cent. is serving as a working basis. All this difficulty could readily be eliminated by including in the standard a definite upper limit of foreign material of this character.

In the case of belladonna root, additional problems confront us. This commodity is frequently found adulterated with material which undoubtedly has a tendency to materially influence its therapeutic action, as well as that of the finished product made from same. This root often contains "punky" belladonna root and is frequently mixed with such foreign agents as poke root, scopola root, etc. In the early part of our work that adulterant in a few cases exceeded seventy-five per cent. Such cases are of course readily disposed of, but the question, however, presents itself, Is it desirable to permit the presence of any foreign material of this character? If the foreign material possesses medicinal properties which would in any way influence the primary action of belladonna root or preparations made from same, its presence should be rigidly forbidden. It is true, as contended, many of these roots are gathered by ignorant, uneducated people, and the introduction of small quantities of foreign roots similar physically to belladonna root is naturally to be expected. This undoubtedly deserves consideration, but experience shows that if such sophisticated goods are denied admission into the United States, ways and means appear to be found to eliminate the foreign material. It would seem, therefore, that in cases of this character the proper course to pursue is rigid exclusion.

No product has probably presented more difficulties than saffron. No standard for this product exists, in the present edition of the Pharmacopoeia, but in section 7 of the Food and Drugs Act, part 2, it is stated in substance that if an article falls below the professed standard of strength, quality or purity under which it is sold, it is adulterated. This is construed to mean, for example, that if an article is sold under the name saffron it must comply in quality, purity and strength to a good grade of saffron and if there is a standard which can be utilized as is the case with saffron, the use of such standard is perfectly proper. On referring to the 7th edition of the U. S. Pharmacopoeia it will be found that saffron is described as "The stigmas of Crocus sativus." This is further supplemented by a description of the article and with certain chemical and physical tests. On account of the character of the article and price of same, it is but natural to encounter difficulties. It is well known that saffron has been most liberally adulterated in the past with various substances, such as artificially dyed ligulate florets of calendula officinalis, tubular florets of
carthamus, yellow filaments obtained from the saffron plant itself, inorganic material such as calcium carbonate, calcium sulphate, barium sulphate, potassium nitrate, etc. Definite limitations are made relative to the amount of moisture and foreign inorganic material that may be present. The yellow plant tissue, etc., can readily be restricted to the styles derived from the saffron flower itself, but the permissible amount is a fruitful source of contention, in that no definite information is available on the subject. For a time saffron containing a goodly portion of this yellow material was permitted entry with the result that numerous complaints were received to the effect that if the admission of adulterated saffron were continued, parties engaged in the handling of the pure product would be driven out of business. An examination of saffron available in the American market at the time of these complaints showed that the complaints were not well founded. It however prominently brought up the question as to the maximum amount of the yellow material that might be permissible. Viewed from a purely monetary consideration, manipulation of saffron to the extent of five per cent., would be a lucrative business. An investigation soon showed that such a limit would be too stringent, but it was found however that a good grade saffron was available which did not contain to exceed ten per cent. of such material. This is the basis of action at present but numerous complaints are received to the effect that this standard is still too rigid for existing commercial conditions.

In the above I think I have clearly set forth the conditions obtaining and difficulties encountered relative to standards in vogue for certain commodities. I think it is furthermore clearly evident that it is incumbent on those who are charged with providing these standards to include in same, definite information as to the amount of certain foreign substances that should or should not be permitted to be present.

MR. SAYRE: I am glad I was present to hear this paper read, and am very glad it has been presented in this Section, where I think it belongs. I want to say just one word in support of the recommendation that was made. At first sight it may seem rather theoretical and impracticable, but when you come to think of it I don't believe it to be so. There was a time when we did think it impracticable to fix a limit upon the maximum amount of impurity that might be contained in certain articles; and it does strike one at first that it is rather impracticable to fix a limit of impurity in the case of vegetable products, but as a member of the Committee on Drug Reform I have had some work to do on this, and a paper upon the subject will be read tomorrow or the next day. I do hope this Section will support that recommendation, because it will then come from the place it ought to come from—the Commercial Section. It seems to me if we could get the support of this Section, it would be a great benefit. Now when we say we would like to have the maximum limit of adulteration fixed, we do not say that every drug can be standardized at once; but I do believe that the time is coming when we can fix the limit of adulteration. We are doing it in our laboratory constantly. Some of you know, perhaps, that I have upon me the responsibility of the laboratory of the State of Kansas, under the Pure Food Law. Now it is practicable for us to say
what would be the maximum of adulteration we would allow in certain spices, and it is true we can also fix the maximum in the case of buchu, and drugs of that class, and I hope that the Committee will be instructed to fix limitations, and also to give a method by which this maximum amount of adulteration can be ascertained.

The Chairman: Is there any further discussion on the paper? Mr. Dohme, haven't you something to say on this subject?

Mr. Dohme: I heartily concur in what I heard Mr. Sayre say. I think the question of the ascertainment of the maximum amount of adulteration is a practical one, and will in a great many cases help us out of difficulties. Of course it will in a great many cases meet with opposition on the part of the general public, and will be misinterpreted, I think, to a large extent, but it seems to me that we are perfectly justified in not demanding too much, of a great many products which it is impossible to obtain in any pure shape, in a commercial way, and from my own standpoint I should feel rather favorably disposed towards the proposition.

Mr. Meissner: This should also apply to a drug being above the standard required by the U. S. P. There should be a limitation either way; it would be only fair to allow a slight variation, because we do sometimes find that where we insist upon the U. S. P. standard, we get a better grade.

Mr. Wetterstroem: I hardly believe that any percentage would cover in all cases. In our Ohio law some years ago we had this question before us and we tried to overcome it by inserting in the law the two words "material difference." That is, where the product differed materially, beyond the standard of the Pharmacopoeia, then it was adulterated. We worked very hard to get that placed in our law, but we could not do it. We finally came to the convention in 1900, and there used what influence we could to have the word "rubric" placed in the law, but even then we find that it is not sufficient. It seems to me if any deviation is allowed, say 10 per cent., they will take 20; or if you allow a 20 per cent. deviation they will want 40, and any figure you adopt will always be taken advantage of and they will go a step further; so I do not believe that any stated figure, in any preparation named in the Pharmacopoeia, can be used, but that some phrase, such as "material difference," used in the Pharmacopoeia, would cover this question.

Mr. Emanuel: It seems to me that there are two ways of enforcing the law—one an arbitrary way and the other a dangerous way. It is dangerous to give the commercial side too much rope.

Mr. Meissner: Some time ago the State Inspector called at my store and tested some spirit of camphor, and I recently received a communication from the official in charge of the Drug Laboratory to the effect that the camphor ran 90.8, and asking me if I had any more of the goods in stock exceeding the amount of alcoholic strength. I had not tested the last alcohol that I had received, and apparently this alcohol had exceeded the required strength, and according to the State law it was as illegal as if it was under.

Mr. Sayre: We have found the strength of spirit of camphor in the State of Kansas as high as 17, an.1 as low as 3, and all proportions of water and alcohol. As to the percentage of alcohol, that is, whether you have a 95 or 94 per cent.—or a 188 proof or 190 proof, as the case may be—we found that there was being shipped into the State nothing but the 188 proof. We made complaints to the distiller, and the distiller said it was perfectly absurd for the officers of the food and drug law, or for the United States pharmacopoeial authorities, to insist upon any higher than 188 proof being shipped into the State;
NOMINATIONS FOR OFFICERS.

that it would require a change in their outfit, costing thousands of dollars, to make a different kind of alcohol, even a fraction more per cent. than that. Of course I accepted that statement and reported it to Topeka, and then they authorized me to correspond with the different manufacturing houses and distillers and ask them about what kind of alcohol they were putting out, and what kind of alcohol was being received. One large manufacturing house reported on the specific guarantee from 100 different barrels, and none of them went below 96 per cent. They said that usually, in order to get the official strength, they reduced it with water; that they always considered it cheaper to pay the freight on alcohol than on water; and the manufacturers and most of the distillers said it was perfectly practicable to put out a 96 and even higher percentage of alcohol.

The Chairman: Is there any further discussion on the paper? It seems to me that possibly the latter part of this discussion has gone a little wide of Dr. Kebler's paper. The Chair would suggest that there ought to be a motion offered to the effect that the Section concurs in the views expressed by the paper.

A motion was here made, seconded and carried that the Section concurs in the views of Mr. Kebler; that certain limitations should be made in the fixed standards of certain drugs.

The Chairman: Inasmuch as the remaining papers on the program, while very interesting, are not exactly original, having been before presented to the Pittsburg Branch, and as it has been decided that we would forego our meeting for to-morrow afternoon and attempt to close up the business of this Section to-day, we will now listen to the nominations for officers for the Section for the ensuing year, and then proceed immediately to the election of such officers.

Mr. Meissner: I take pleasure in nominating for the office of Chairman of this Section for the ensuing year, the present Associate, Franklin M. Apple.

The Chairman: Are there any further nominations?

There being no further nominations, on motion duly seconded, nominations were closed, and the Secretary cast the unanimous ballot of the Section for Mr. Apple as Chairman.

The Chairman: Will some one nominate a member for Secretary?

Mr. Benjamin E. Pritchard, of Pittsburg, was here placed in nomination for Secretary, and on motion, duly seconded, the nominations were closed, and Mr. Pritchard was unanimously elected.

The Chairman: Before proceeding to the nominations for Associates, I want to call your attention to a deplorable thing that has happened this year, and has happened before, and that is, that the Associates in this Section have all come from one portion of the country. This makes the work of the Chairman hard and hampers the whole Committee, and I would suggest that this time we try and scatter them. If you can find someone from the Pacific Coast, another from the middle West, and another from the West, say—inasmuch as the two officers of the Association are from the East—it would make the work easier.

The following were placed in nomination for Associates on the Committee: Mr. Sidney Yeomans, of Chicago; Mr. Charles Ford, of Denver; and Mr. W. Withers Miller, of Richmond.
On motion, duly seconded, the Chairman was authorized to cast the unanimous ballot of the Section for the gentlemen named; which was accordingly done.

The Chairman: I have the honor of presenting to you Mr. Apple, Chairman for the ensuing year.

Mr. Apple: Mr. Chairman and Fellow Members of our beloved Association: It affords me pleasure, indeed, to accept the chairmanship of this Section. As you well know, I have served in the same capacity in another Section—that of Practical Pharmacy. I realize that while it has not received the attention from the rank and file of the members of the Association, that it should have had, that nevertheless this is a very important section. You must concur in that, when you remember what our worthy President brought forth in his address, and also the admirable things in the address of our chairman. Remember when you elect a Chairman of this Section that he is not a working committee of one, with whom is associated the Secretary and three Associates. They simply can be guiding spirits for you, and when they accept service from you, you must not refuse to accept service from them. Hence, we ask now for the support of all of you, and of all your friends, and that you will help us to make this Section a grand success during the ensuing year—and kindly do not let us ask in vain. I thank you again.

Mr. Mayo: It affords me pleasure to introduce to you the only "Consulting Engineer of Pharmacy" in existence. Some people go out of pharmacy because they have made enough money to quit; some go out of it because they have lost so much they can not remain in it, and some men go out of it because they die. This is the only man I know of who has gotten out of Pharmacy because he knows all that can be found out in it, and wants to give to others the benefit of his information. I think it eminently fitting that this gentleman should act as Consulting Engineer for this Section, and tell us how to make money, so that when we have been in the business twenty-eight years, as he has, we too can go out.

Mr. Pritchard: Mr. Chairman, I have never had a load so heavy to carry on my shoulders as that which Mr. Mayo has laid on me. I must confess that there were other reasons than those he assigned, for my leaving the business; he forgot to mention them to you. The real reason I left my store was because I had a clerk who had worked for me fifteen years, and he concluded it was about time for him to be boss, and I could not work under him. That does not indicate that the clerk made more money out of the store than I did, but it does indicate that if you have a real good clerk, and have built up a fairly good business, and that clerk thinks he has done his share towards building it up, you ought to give him a chance; so I thought when an opportunity came, and I had enough to do with my other business, without conducting a drug store, I would drop out and let my clerk, who had been conducting the business for fifteen years, have a piece of the pie. In the affairs of the Western Association, in Pennsylvania, and of the paper I conduct in connection therewith, I find that I have all that it is possible for one man to attend to. In talking with the Secretary of the Pennsylvania Board of Pharmacy, a few days ago, I was compelled to acknowledge the fact that notwithstanding I had put in 40 years in a retail drug store (28 years for myself) I have actually learned more of pharmacy in the two years I have been out of business, than during the 40 years I was in harness, because during those 40 years my mind was continually occupied in trying to keep the cash register going, so that the income would be sufficient to meet the outgo. So if you want to find out things, and know as much as I am alleged to know about pharmacy, by a friend of the "American Druggist," get out of
the business and be a "Consulting Engineer," and then you will get jobs like this that will pay you handsomely, and enable you to make a fine living.

The Chairman (Mr. Apple): It is certainly very assuring to the Chairman to have a Consulting Engineer right at his hands at any time he needs assistance, and I am sure that he will find me consulting him quite frequently. Are any of the Associates here, that they may be installed? Mr. Anderson, will you escort Mr. Ford to the platform; and you, Mr. Ladish, perform the same office for Mr. Yeomans?

Mr. Yeomans and Mr. Ford were here escorted to the platform.

Mr. Yeomans: Mr. Chairman and Gentlemen: All I can do is to make a grateful bow, on behalf of Mr. Ford and myself.

The General Secretary: Mr. Chairman, I heard the name of Mr. W. Withers Miller, of Richmond, mentioned for Associate. I do not think Mr. Miller is a member, unless he has joined at this meeting, has he?

The Chairman: He has not. I presumed from the fact that he was requested to act as Secretary, he was a member of the Association.

Mr. Anderson: If Mr. Miller is not eligible, I will nominate Mr. Berger, of Florida.

On motion, duly seconded, the nominations were closed, and Mr. Berger was unanimously elected an Associate on the Committee for the ensuing year.

Mr. Berger: Gentlemen, I appreciate the honor and will certainly be glad to do everything I possibly can to assist the Chairman and other associates in their work. I thank you.

By a motion duly made, seconded and carried, the thanks of the Section were extended to the outgoing officers for the faithful and efficient manner in which they had conducted the business during the past year.

On motion, the Section here adjourned.

Papers read by title:

**Sunday Closing.**

*By R. A. Leet, Oakland, Cal.*

There are but two possible reasons for keeping a drug store open on Sundays, either the money that can be made by keeping open, or else the desire to serve the community represented.

In discussing the advisability of Sunday closing, it is necessary to take into consideration the problem which it involves to the druggists at large throughout the country. To some of these it is certainly a much simpler proposition than it is to others.

I heard it stated recently, that as a result of a widespread investigation based on data taken from all parts of the country, the average income of the physician in the United States is estimated to be less than $2.00 a day. I don't know if the average income of the drug store proprietor has been estimated, but I think that it is safe to say that if we could canvass the sit-
uation as widely, we should find that it is not greatly in excess of the cost of living. Accordingly, one of the first things that he has to consider in any new proposition put up to him, is whether or not he can afford it.

I think that the proposition of Sunday closing appeals strongly to the average druggist throughout the land, and I think that the hesitation in adopting it is mostly due to the fact that he does not feel sure that he can afford it. I know that the desire to serve his community, to be always at hand when a case of real urgency presents itself, also influence him largely. But I think it goes without saying that any proprietor would be very glad to join the Sunday-closing movement, if you can convince him of these two points; that it would not be at a pecuniary sacrifice, and that he would not have to account to his conscience or his clientage as to his service to the community which he represents in their time of need.

It is only because that the firm with which I am connected has had experience that may assist some of the druggists who are considering this question to come to a conclusion that I have consented to write this paper, and give the facts that have been developed in our own case.

We commenced closing our stores on Sundays except between 9 a. m. and 2 p. m. in 1907. At that time our business on Sundays was a very substantial portion of our whole business—large enough so that if we lost it without any corresponding gain through the week, we should be very seriously crippled.

After nearly three years now, we feel that we are prepared to speak on the question of pecuniary loss, and feel that if there is any at all that it is so very slight that the advantages and benefits accruing far more than offset it. Our receipts of course were very much reduced on Sundays, but we think that they were sufficiently augmented during the week to offset the reduction. We feel certain that as a result of our better hours, we have had a choice in the selection of clerks such as we would never have had otherwise. We know that good men have been influenced to place their application with us by reason of our Sunday closing and we feel that the morals of our working force are on a higher plane. We feel that on these accounts alone we are more than repaid for the stand that we have taken; and be it understood, we are absolutely independent in this movement, having closed our stores regardless of the fact that our competitors all around us keep open. So much in answer to the question of pecuniary loss.

Now as to the matter of serving the public in their necessity. In our case we have closed our doors and drawn our curtains, but we have had a notice on the doors that we would still be ready to fill prescriptions and supply urgent requirements. By this arrangement we have been able to adjust our shifts so that it is not necessary for any man in our employ to work all day on Sunday oftener than about once in eight weeks.

We believe that in smaller communities, or in the case of stores less
prominentely located, the stores could be closed absolutely except within
certain hours, and that any urgent need could be taken care of by having
the address of the proprietor or his clerk posted on the door so that he
might be called on. We adopted successfully such a course as this latter
with regard to our night clerk service. We discontinued a night clerk
service after it had been in force for thirty years, and we have yet to hear
a substantial complaint either from a physician or a customer. The num-
ber of impositions have been very small indeed, and in fact the number of
calls has been minimized. As a matter of fact we found by keeping actual
count of our calls for a period of a year before abandoning our night clerk
system that the percentage of really necessary calls was very small indeed,
and we feel sure that if a drug store is kept open for a certain few hours
during the day on Sunday and perhaps for one hour in the evening, and
the public made fully aware of the fact, that the percentage of calls out-
side of these hours that are entitled to consideration will be extremely
small.

Accordingly I think that the druggist who can satisfy himself that he
is justified in adopting Sunday closing from the dollar and cent point of
view, can readily find a way to see that his clientage suffers no great in-
convenience by reason of his action.

Now there are some few important details to be considered once Sun-
day closing is decided upon. In the first place, it is very important that
you should not take any action that would appear arbitrary to your cus-
tomers. You will find them practically unanimously in favor of any move-
ment for the betterment of hours if it is presented to them properly, and yet
the same people will freely criticise you as being independent and indif-
ferent to their urgent needs, if you do not take them into consultation
regarding any shortening of hours of your service to them. Moreover, by
acting arbitrarily you will leave an opening for a competitor to insinuate
your indifference of suffering and to emphasize this readiness to nobly
serve every hour of every day, Sundays as well as all other days.

In our own case we first of all sent out a personal communication to
each physician, telling him it was our intention to close, if our plan was
agreeable alike to the physician and the community at large, but empha-
sized the fact that regardless of our desire to better our conditions, and
that of those in our employ, we realized that our first duty was to minister
to the needs of our patrons, and that in the case of a very small percent-
age of unfavorable replies, we should consider our plans. We then sent a
similar notice to each customer whose name appeared upon our books and
simultaneously placed large advertisements in the local papers, setting forth
our reason for making the movement, and asking for an expression of ap-
proval or disapproval. The returns far exceeded our expectation. The
personal communications were responded to almost without exception, and
we received literally thousands of signed coupons cut from the papers. In
addition to this, we received coupons bearing long lists of signatures of the employees of some of the larger establishments, and not a few expressions of approval from labor organizations. There were but two unfavorable answers amongst the thousands of replies received.

With this substantial endorsement, we entered upon our plan with enthusiasm, and at this time, after nearly three years of trial, we repeat what we have often said before, that there has been no single action in connection with the conduct of our business that has afforded us so much satisfaction as this one of Sunday closing.

I urge upon the druggists of the country its favorable consideration. If we are to make our calling attractive to the better class of men, we must make it a business rather than a grind. With the advent of men of high standards of living, competition will be on a fairer basis, and the returns for our efforts will be more satisfactory.

Conditions have been bettered in almost every other line of business, and it is high time that they should be bettered in ours. Already our calling has suffered much by reason of the turning away of our young men to callings that allow of more opportunities of development and culture, and social enjoyment by reason of their shorter hours.

Let us do what we can to further and prosper the movement for shorter hours, for by so doing we increase the welfare and advance the respectability of our calling.

THE COMMERCIAL GROWING OF EUCALYPTUS FOR OIL.

BY EDWARD C. BINZ, LOS ANGELES, CAL.

The extensive advertising of eucalyptus has aroused considerable interest in its growth as an industry and, among its many uses its possibilities for the manufacture of eucalyptus oil. There is no doubt that in time, eucalyptus will rank with gold and petroleum in making the reputation of the state of California.

Eucalyptus has been brought to the attention of the public and into popular use, that the pharmacist and the physician are now realizing that this is a valuable drug and that it has been neglected by them for some years past.

Eucalyptus now holds an important place in genito-urinary work and with the gynecologist, with the surgeon, the nose and throat specialist, the skin specialist, and general practitioner.

Eucalyptus is a good anti-malarial, an antiseptic, a germicide, a stimulant to indolent ulcers and all mucous membranes, is a good pus destroyer and an insecticide.

In taking up the commercial possibility of the manufacture of the oil of eucalyptus we must consider all phases of the same.

First, the supply and demand: this we know, is what will regulate the price and is what influences the advisability of entering upon the manufacture of the oil.
The demand, to-day, as far as my observation goes, does not exceed
the supply. I have called upon the wholesale druggists from coast to
coast and not any of them are having trouble in procuring all the oil at
any and all times and at the low prices of 30 and 35 cents per pound.
For this price they obtain an oil which fills the requirement of the phar-
macopœia and that is all the average pharmacist seems to exact. The
oil that they buy is a very good commercial oil and may be produced at a
fair profit, in Australia, at the present price, as for several reasons labor is
cheaper. Men, women and children of the poorer classes gather great
quantities of the leaves and sell them to the distiller at a nominal price.
No attention is paid to the variety of the eucalypt on which they are
grown. The wage paid to the employees of the distiller is from $1.25 to
$1.50 per day.

They have large forests closely grown, material in fact, that will keep a
plant busy all the time, and an established market in England and in all
of Europe as well as America.

They have varieties of the eucalyptus that will produce or yield from 3
to 4 per cent. of oil and will run high enough in eucalyptol content to
stand dilution and yet bear the test of the Pharmacopœia.

In California our groves (and groves is what they are, not forests) are
too far apart to make it possible for any one to establish a large plant for
the distilling of oil. We are obliged to haul the leaves for from 3 to 4
miles. This means a team, wagon and a man, at the expense of at least $4
to $5 per day for it takes time to load and unload the leaves. Wages here
are from $2 to $2.50 per day for ordinary labor which is not very plentif-
ful at that.

In California, we have principally the Eucalyptus globulus and, in fact
this is the only variety grown here at present, in quantity sufficient for
manufacturing oil and securing a product that will stand the Pharmacopœia
test. Our oil will go way beyond on the required eucalyptol con-
tent, but our yield is only a fraction over 1 per cent. of the amount of the
leaves handled. This means that we must handle a ton of leaves to get 20
per cent. of oil.

Our market is limited and we cannot at present cost of production com-
pete with oil that is sold at 30–35 cents per pound. The jobber as well as
the retail pharmacist only recognizes eucalyptus as eucalyptus and does not
consider quality. I mean that this is the case in commercial channels.

California may, in time, after the groves being now planted mature, hope
to compete with Australia in the oil manufacture, but never, under present
conditions, to any great extent.

In securing our material, the leaves (as the leaf only produces oil), we
have to wait until the woodman cuts the trees for cord wood or for lumber.
It takes too many leaves for the regular trimming of the trees to be prac-
tical for oil making.
California oil is superior in quality to the Australian.

Eucalyptus oil is just as different in its therapeutic effect as to the variety from which it is distilled as are the different pine oils. We know the Pinus pumulus is not Pinus sylvestris, and so it is with the various eucalypts. There are over 150 varieties of the eucalypts, and while they are all similar and belong to the same family of the Myrtaceae, the oils are not the same in therapeutic action.

I am satisfied, after careful consideration of the literature at my disposal, that the physiological effects as laid down in our Pharmacopoeia are based upon the experiments made some time ago, at the first discovery of the Eucalyptus globulus, and I think that this was the only tree known of the eucalypts at that time. The experiments were carried on by Prof. Gimbert, of Italy, and by Prof. Carl Binz, of Bonn, Germany. Since that time physicians have been using eucalyptus oil, and some with the effect as laid down in these experiments, while others have failed and condemned the remedy. These failures, in my estimation, have been due only to the use of inferior oil, or possibly an oil not from the globulus.

I am anxious that the pharmacist should realize the fact that there is a difference in the many oils of eucalyptus as to their variety. You may ask: "If eucalyptol is the active principle of the oil, then why not use the eucalyptol?" True; but the oil contains a good percentage of pinene which nature produced in the leaf and which is just as essential in enhancing the therapeutic effect as is the eucalyptol. We know that you do not get the same action from strychnine as you do of nux vomica.

I offer this as food for thought, because, if we can educate the pharmacist as well as the physician to this fact, that the pure oil of Eucalyptus is essential if they expect results, we know that in time they will appreciate this fact and will then be willing to pay a price that is consistent with pure, first-class oil.

In conclusion, I would like to say that I think there is also a place for a distilled extract of eucalyptus, that may in time take the place of witch hazel. I trust this paper will appeal to the members of the Association, and that the subject may have proved interesting to all of you.
MINUTES
OF THE
SECTION ON EDUCATION AND LEGISLATION.

First Session—Thursday Morning, May 5, 1910.
The first session of the Section on Education and Legislation was called to order at 10:30 a. m. by Chairman Charles H. LaWall, of Philadelphia, who announced that the first order of business before the section was the reading of the Chairman's Address. In the absence of any of his Associates on the Committee, he said he would ask President Rusby to preside, while the Address of the Chairman was being presented, and Mr. Rusby took the chair. Mr. LaWall then presented his Address as follows:

ADDRESS OF THE CHAIRMAN.

Gentlemen: When more than two hundred years ago Leibnitz said "Give me control of education for a generation and I will change the world," he uttered an aphorism which needs but the interpolation of the word "pharmaceutical" to make it applicable to our own time, country and profession.

Education and legislation are two subjects concerning which there should be a natural relationship, but unfortunately this relationship has at times been somewhat obscured by a lack of coordination between the theory and practice of attaining results in both instances. If educators were more frequently found in the ranks of the legislators or if legislators were sometimes better educated concerning the specific subjects with which they are dealing, there would be much less friction. Energy which is now dissipated in attempting to move a body in diametrically opposite directions at once would be applied with much greater effectiveness if applied harmoniously with regard to ultimate results rather than present emergencies.

It is always found that where the cause of education is properly advanced, legislative improvement results as an inevitable corollary, and the reverse of the proposition is also true, for wise legislation always stimulates progress along educational lines. A prominent university president is authority for the statement that "the ideal education is where a student learns things that he is not going to use in after-life by methods that he is going to use." This is more in the nature of a defense of past conditions, especially along general educational lines, than a true statement of fact as applied particularly to professional education. In pharmacy, as well as in medicine, almost every subject taught is of direct value to the student in the subsequent practice of his profession.

Education in any profession and especially in pharmacy should strive to develop the
individuality of the student. The graduate should be equipped to deal effectively with any problem which may arise after he has been thrown upon his own resources and he should be taught, not so much to memorize facts as to learn where and how to lay his hands upon information of a specific nature.

There should also be an attempt to develop what is known as a scientific imagination. This faculty enables its possessor to foresee possibilities and suggest means of accomplishing results and to successfully cope with unusual problems when they arise.

Much of the responsibility for results in education naturally lies with the teacher rather than in the system of instruction followed. The effective teacher will so stimulate the interest of his pupils that they will discuss out of the class room subjects and problems that have been presented to them within its walls. In other words, the teacher must possess a contagious form of education, which must not be counteracted by the sterilizing effects of inattention or lax discipline.

While the individuality of the teacher is recognized as a factor of prime importance, it must be admitted that it counts for much more when combined with a system of instruction which is fundamentally sound and which is so elastic as to admit of constant improvement and change to keep pace with the progress which is continually being made in the various sciences which constitute the foundation of a pharmaceutical education. A didactic or lecture system based upon notes or text-books followed year after year with occasional revision of minor points is not sound. A lecturer who reads from manuscript or text-books is likely to do so perfunctorily and the student fails to gain inspiration and interest, while the teacher who previously prepares for each lecture by consulting the latest information upon the subject and who imparts it in a manner that indicates his own personal enthusiasm in the work will send out into the professional world the kind of men who are needed to develop and perpetuate the highest ideals.

Lecture experiments of an illustrative character must be successful in order to be convincing, and nothing causes a student to lose interest more quickly than a neglect of this consideration. Lecture experiments should be given at such times during the lecture as are most suitable and effective from the teaching standpoint, and it is rarely a good plan to conclude the lecture first and then lump all of the experiments together as a finale. Such a procedure produces a chaotic impression upon the mind of the student and often leads to the acquirement of what is known as "misinformation," a condition which is all too common and the seriousness of which is often overlooked by teachers.

Another important point is the necessity for synchronism between lecture and laboratory instruction. The student who does not have an opportunity to apply practically the knowledge of a given subject until weeks after the subject has been theoretically presented, or, what is still worse, who has practical work in connection with subjects that have not yet been presented theoretically, loses much in comparison with one who has an opportunity to apply practice with theory throughout his course.

The effectiveness of educational work is furthered by properly stimulating healthy competition, and most institutions, in recognition of this fact, offer prizes which are awarded at the end of the respective courses. What is needed still more is some practical method of rewarding continuous effort during definite periods, so that at certain times during the college year a student who merited approbation for the character of his work would receive some tangible reward in recognition of the fact. This might take the form of an honor badge, of no great intrinsic value, to be worn for an assigned period. At the expiration of this time it would either be re-awarded or transferred to some more deserving student. The effect would be to stimulate continued effort, which is the only kind that gives lasting results, and every possible plan should be adopted to discourage the idea so frequently held by students that it is passing the final examinations that constitutes an education. With this end in view, examinations should be relegated to their proper place in the course and not magnified unduly as to their im-
portance. It is well to occasionally hold a written examination where the student is permitted to bring and use his text books. Questions may be framed so as to compel the use of the reasoning powers and the student is at the same time instructed in the art of looking things up, which is sometimes more important than trying to remember them bodily.

In all educational work it will be found difficult in some cases to counteract the sterilizing effect of the influence of cynical druggists of former generations, who, while acting as preceptor, take especial pleasure in shattering the ideals of young and enthusiastic students, thereby retarding the professional advancement of pharmacy.

There is a question whether it would not be advantageous to construct an education system in pharmacy based upon a judicious plan in which electives are permitted. Many students enter a pharmacy college with a well-defined idea of their future life-work. Some would prefer to specialize in chemistry, others in microscopy, while still others expect to devote their attention to pharmaceutical manufacturing, and by having a minimum requirement for these and other major subjects, it would enable many students to avoid spending time upon subjects for which they would have less practical use than some others.

In this connection it may be suggested that the time is now ripe for the introduction of elementary bacteriology into our pharmacy colleges as a compulsory branch of study. Information on this subject is of prime necessity to the pharmacist, especially in connection with antisepsis and sterilization, both of which are becoming popularized and are even receiving a certain amount of attention in some of our public schools.

Business ethics is also a matter that should receive more attention than has been given it in the past. If this subject had been properly and intelligently presented by forceful and convincing teachers in all of our pharmacy colleges during the past twenty-five years, some of the ills which now beset the profession would not now exist. When a student has been trained in a drug store by a preceptor who has lax views regarding the sale of certain articles, and who perhaps belongs to the class of substitutors, and if during his college course he hears no word of condemnation of such practices, he is tacitly encouraged to do as he sees others do and is not to be judged too harshly if he follows such practices when he embarks in business for himself.

Conditions regarding entrance requirements are at present in unstable equilibrium and the ultimate remedy will be found in the hands of the legislators who frame future registration laws. There is danger of excessive zeal in this respect working against the best interests of the profession from a practical standpoint. A registration law requiring graduation from a reputable college, four years' high-school training and four years' practical store experience is a combination that would cut down registration to a point where the proprietors would rise up in unanimous opposition, as clerks would be practically unobtainable until a revolutionary readjustment had taken place.

In this connection I would call attention to the injustice of many State laws which at present require an applicant for registration to obtain four years' experience in a retail pharmacy, although the practical work may have been largely confined to the soda counter, while an applicant who has had many years of experience in government or any other hospital service, where the whole time may have been spent in compounding or manufacturing medicines, is denied the right to take the examination under the State Board.

The beneficial effect of the few States that have judiciously raised the standards of pharmaceutical education has been already felt, even in parts of the country that would seem to be remote from their influence, and there has been a total disappearance of the diploma mills which some few years ago handed out educational goldbricks to the ignorant or mercenary.

Great progress has been made in recent years in educational matters as they apply to the colleges, but the necessity for education in its broader sense, where all are students,
has not yet been realized by the rank and file of the profession. Of pharmacists in general, how many have kept up their studies and their interest in the purely professional side of the business, save when it has been a matter of dollars and cents? How many know less now than when they were graduated, losing sight altogether of the fact that the acquisition of a college diploma is but a single rung on the ladder of education? How many toss their pharmaceutical journals aside after a cursory and perfunctory glance at the headlines and the news items and are oblivious or indifferent to the necessity of keeping alive to the numerous discoveries and ever-changing requirements of the progressive sciences which constitute the foundation of our profession? To one who is careless in this respect the very terminology becomes unintelligible in a few years. You will look in vain in a dictionary of ten years ago for such terms as bacterin, hermod, kinase, opsonin, radium, radioactive and numerous other words which are in constant and current use at the present time.

The blame for much of this lack of progressiveness in certain directions undoubtedly rests upon the individual. The pharmacist should be an educator of the public along broader lines than ever before, and in fulfilling the function of a popular educator he becomes convinced of the necessity of keeping better posted himself, and thus the cycle is completed. He has, however, been remiss in his duty toward the public in some important matters. It has been stated, and truly, by a well-known medical authority, that "the only instructor of the public in matters pertaining to disease has been the charlatan who advertises in the daily press." The pharmacist, having participated in the profits arising from the sale of worthless or even harmful nostrums, without a word of protest, is almost entirely responsible for conditions which are now recognized as being inimical to the best interests of the profession. Too many pharmacists are embryo nostrum manufacturers, only awaiting a favorable opportunity to reap the golden harvest of profits accruing from the sale of preparations whose very existence is dependent upon misrepresentation of their value and the credulity of the purchaser.

To the pharmacist belongs the duty and the privilege of disseminating information concerning recent food and drug decisions and notices of judgment, and also concerning the work of the Council of Pharmacy and Chemistry of the American Medical Association. Has he qualified himself to fill this important position? In most cases, he is the one requiring instruction. Has he aided in educating the public with regard to the reliability of newspaper advertising of medical specialties and nostrums? On the contrary, he frequently gives tacit endorsement to such preparations by allowing his name to be used in connection with such advertising as that of a reliable (?) druggist from whom such preparations may be procured.

It is an indisputable fact that much of the newspaper advertising of cures and nostrums is an insult to the intelligence of the average well-informed reader, but how often do we find the pharmacist raising his voice in protest against such barefaced misrepresentation as characterizes the preparations which are constantly being exploited through the medium of newspaper advertising?

The necessity is now greater than ever for standing shoulder to shoulder with our brother pharmacists and with physicians in the important work of advancing the interests of the twin professions, medicine and pharmacy. Very recently there have appeared in reputable periodicals, articles, which from the unfairness in the treatment of the respective subjects should have aroused a storm of protests not only from individual pharmacists but from the pharmaceutical journals as well. One of these was a condemnation of the use of Latin in the nomenclature of science and in prescription writing, in which no mention was made of the advantages of conciseness and exactness. The other was an attack upon the metric system in which its primary advantage, i.e., the commensurability of the unit, was entirely ignored.

Unless the rank and file of pharmacists soon awaken to a sense of their responsibi-
ties in the foregoing matters as well as in other directions not mentioned, there may come a fulfilment of the frequently expressed prophecy of a division of the members of the profession into two classes, one of tradesmen whose energies shall be restricted to handing out what somebody else has put up, and the other of professional pharmacists in the true sense of the word, who shall enter into the heritage which has awaited them for many years.

The pharmacist fills a peculiar place in the estimation of the public. He is looked to for counsel and advice upon subjects innumerable, and when he once realizes his responsibility to the public, his fellow pharmacists and himself, there will arise a new era in pharmacy, in which education and legislation will be paramount issues, free from domination and uncontrolled by class or local factors.

To conclude in the words of Milton, which are peculiarly appropriate:

"I shall detain you no longer in the demonstration of what we should not do, but straight conduct ye to a hillside, where I will point ye out the right path of a virtuous and noble education; laborious indeed at the first ascent, but else so smooth, so green, so full of goodly prospect and melodious sounds on every side that the harp of Orpheus were not more charming."

President Rusby said it was very refreshing to him to hear an address of this kind on the subject of education—an address that went right down to the roots of the matter, and the workings of the human mind. He did not hear the title of the address as read, but he thought it might well have been called "The Psychological Aspects of Education." He said he had very greatly enjoyed it, and this was the kind of address the members wanted to hear, where the principles of teaching were considered. He thought a good many of the members, and especially the pharmaceutical educators, were apt to forget that there was a science and an art of teaching; and the art of teaching was just as much a subject of study and research as any branch of knowledge that was taught the students.

Mr. Hallberg said he had listened with great pleasure to this splendid address, but he had one criticism to offer. The medical profession had been separated in the minds of many into two classes for many years—the doctors and the physicians; and he believed that those engaged in the practice of pharmacy should also be separated into two groups, druggists and pharmacists, and he would have enjoyed the reading of this address more if the Chairman had distinguished in the use of these two terms. He thought there would have been a little more suggestion in one or two of the points made if he had said "druggists" instead of "pharmacists," and vice versa.

Mr. Stewart moved that a Committee on Chairman's Address be appointed, as it was certainly full of meat, and it would be a pity to let it go without further attention.

This motion was seconded by Mr. Kebler and Mr. Apple, and carried.

The Chair said he would appoint as a Committee on Chairman's Address Messrs. J. T. McGill, of Nashville; A. B. Huested, of Albany, and A. B. Lyons, of Detroit.
Chairman LaWall resumed the chair.

Mr. Remington said, in connection with the subject brought up by Mr. Hallberg, that he felt that, while this proposition of separating the druggists and pharmacists and making two separate departments of activity in pharmacy was coming, he supposed, as the tendency seemed to be that way, and nothing would stop it, he believed it would be much better if the druggist would become more of a pharmacist, and a pharmacist more of a druggist. Instead of a separation between the two classes, he thought the pharmacist should become more of a business man, and become more familiar with commercial transactions than he was to-day; and he thought certainly the hope was justified that the druggist would become more of a professional man, and know more about pharmacy itself.

The Chair called for the report of the Secretary as the next order of business.

Secretary Johnson said it had been rather difficult for him to get up much of a report on legislative matters in the various states, by reason of the fact that very few legislatures had been in session during the past year, and on account of the early meeting of the Association this year, many bills which had been introduced in legislative bodies it has been impossible for him to learn the final action upon. He then proceeded to read his report as follows:

REPORT OF THE SECRETARY OF THE SECTION ON EDUCATION AND LEGISLATION.

During the past year legislation affecting pharmacy, both national and state, has been largely concerned with narcotic and liquor questions. These questions seem to remain live issues from year to year. The general trend of this experimental legislation is to take from the hands of the druggist the responsibility of dispensing these substances except upon the written order of a physician. In the state legislatures the subject of itinerant vendors seems to come next in importance. An occasional bill is found concerned with the purity of drugs or with methods of licensing pharmacists.

STATE LAWS AND BILLS.

Alabama. A pharmacy law passed in August, 1909 provided for the licensing of pharmacists and assistant pharmacists, and prohibits the sale of certain narcotics except on the prescription of a physician, dentist or veterinarian. The name of the person or the kind of animal for which the narcotic is intended must appear. Such prescription is not to be refilled. The law also provides that itinerant vendors must pay a two hundred dollar license tax.

Arkansas. Two bills were defeated, one requiring the word "poison" to appear on certain patent medicines, and one providing for a license to sell patent medicines.

California. Laws passed in 1909 provide for licensing druggists on twenty years' experience without examination, give state board of pharmacy the power to revoke license of a druggist addicted to narcotics or liquor, provide for the sale of certain narcotics on physician's prescription only, and restrict the sale of carbolic acid in less than one pound quantities to a solution containing 10 per cent. acid and 10 per cent. alcohol except on a physician's prescription. A bill failed which proposed to transfer the enforcement of the food and drug law from the board of health to the board of pharmacy.
Colorado. The anti-narcotic ordinance of Denver restricts the sale of carbolic acid, morphine, laudanum, opium and cocaine except on physician's prescription.

Connecticut. A law passed in 1909 creates a commission of pharmacy, provides for the registration of pharmacists and assistant pharmacists and for the registration of stores. The commission of pharmacy must certify to the standing of a pharmacist before he can secure license to sell liquors. This certification must be renewed each year.

Delaware. Bills were defeated to allow physicians to operate drug stores, to give physicians greater power in the enforcement of the state food and drug law, and providing special blanks to be used when liquor prescriptions were written.

Idaho. The pure food law was placed under the direction of the state board of health. A narcotic act was passed providing against the sale of certain drugs except on order of physicians. The local option law requires that druggists in "dry" counties can sell liquor only on physician's prescription, such prescriptions to be filed with the county auditor the first of each month.

Indiana. An itinerant vendors bill and a bill registering all physicians failed.

Iowa. Laws were passed regulating the sale of liquor, cocaine, ergot, cotton root, etc., and permitting the sale of poison fly paper and denatured alcohol. Bills failed permitting the interchange of certificates and prohibiting the sale of liquor by pharmacists.

Maine. Maine has a new law which provides that the dispenser of soda fountain drinks must inform the customer verbally if an imitation flavor is being used.

Maryland. A food and drug bill modeled closely after the federal law was introduced into the legislature, also a new pharmacy bill which provides that no pharmacy be operated under a certificate other than that of the actual owner.

Massachusetts. A bill was introduced authorizing the board of pharmacy to suspend the certificate of druggists found guilty of violating the cocaine law.

Minnesota. Laws were passed regulating the prescribing of cocaine and liquors by veterinarians, relating to the sale of mallein and tuberculin, also regulating the sale of paris-green and other insecticides. A law licensing peddlers and transient merchants was passed and later declared unconstitutional.

Montana. Bills failed to pass relating to the labeling of prescriptions containing morphine, cocaine, etc., and the licensing of itinerant vendors.

New Hampshire. A law was passed regulating the manufacture and sale of preparations containing cocaine. The pharmacy law was amended to allow exchange of certificates.

New Mexico. New Mexico has a new law regulating the sale of certain poisons, also an act making it unlawful to keep or maintain a "hop" or opium joint.

New York. Great interest seems to center around the proposed pharmacy law of New York. A bill introduced by Mr. Hill of Buffalo provides that the board of pharmacy be selected by the board of regents of the University of the State of New York from qualified registered pharmacists of the state. The state pharmaceutical association is allowed to nominate to the regents three pharmacists for each appointment to be made. The bill includes adulterating, misbranding and substituting features of a pure drug law, and recognizes the Pharmacopoeia, National Formulary, Homeopathic Pharmacopoeia and other standard works recognized by the Board. A bill has also been introduced making it unlawful for any corporation to practice medicine, dentistry or pharmacy. The idea is to legislate against the chain-store system. Another bill has been introduced in the legislature restricting the sale of cocaine in the city of New York.

Ohio. Ohio has new laws regulating itinerant vendors and adding certain narcotics to the cocaine law.
Rhode Island. An amendment to the pharmacy law defines a practicing pharmacist, practicing assistant, and regulates the method of becoming registered.

South Carolina. South Carolina has a bill before its legislature to compel applicants for registration to pass examination.

Tennessee. Bills failed to pass providing registration for all who have been in business six years, and to give registration to all assistants of five years' standing without further examination.

Washington. The state board of pharmacy now has the power to prescribe the educational qualifications of candidates for examination and to revoke licenses.

ASSOCIATIONS.

It was aptly stated last year in the Secretary's report that the burden of proper legislative enactment in the various states rests with the state associations. A glance at the percentage of druggists who hold membership in these associations indicates that this burden in a majority of states is carried by a very few. Most of the states report that only 10 to 25 per cent. of the druggists hold membership in the state association. A few notable exceptions should be mentioned. Vermont leads with 93 per cent.; Kentucky follows with 75 per cent.; South Carolina next with 66½% per cent., while some four or five states report a membership of 30 to 60 per cent. Arizona, Nevada and New Mexico report no association.

If, as has been stated, legislation in the states rests with the association, greater efforts should be made to have a larger percentage of active members in these associations. Last year our schools of pharmacy graduated about 1,500 students and they report that an average of 80 per cent. of their graduates enter the practice of pharmacy. Here is an opportunity for the schools to do a work having far-reaching results. Let every school see to it that its graduates affiliate with their state association.

SCHOOLS.

Fifty-six schools of pharmacy replied to the request for information concerning their curriculum. The following subjects are listed by the various schools as belonging to the first year's work: General chemistry, qualitative analysis, physiology, pharmacy, pharmacognosy, English, botony, microscopy, materia medica, physics, plant histology, Latin, arithmetic, anatomy, pharmaceutical testing, United States Pharmacopoeia, toxicology, quantitative analysis, business methods, bacteriology and biology—a total of 22 subjects.

In the second year's work we find the following subjects listed: Pharmacy, prescriptions, organic chemistry, quantitative analysis, bacteriology, pharmacology, toxicology, microscopy, materia medica, commercial pharmacognosy, therapeutics, urinalysis, food and drug analysis, jurisprudence, mercantile pharmacy, physiology, mathematics, histology, dispensing, problems, pharmaceutical economics, accounting, pharmacopoeias of the world, drug assaying, sanitary analysis, commercial microscopy, qualitative analysis, physics, United States Pharmacopoeia, water analysis, physiological chemistry, diseases, hygiene and sanitation, national formulary, crystallography, first aids, minerology, field botany and pharmacognosy—a total of 39 different subjects or 39 different names for studies. Cutting out duplications we have a total of 48 different subjects for the two years' work.

Are the various schools of pharmacy graduating men without uniform training, or do we lack a uniform nomenclature for the studies required of the pharmacy student? I am inclined to believe that we can answer both questions in the affirmative. Is it any wonder that one state board when asked, "What recognition do you give to graduates of schools of pharmacy," answered "None, because we find so many graduates who cannot pass our examination." This state board may have been requiring knowledge of some half-dozen subjects when the graduates had been trained in subjects selected from the other forty. Is it not time for the various schools to get together on the question of cur-
riculum and adopt something, subject matter as well as subject name, which the graduate should be expected to know? Should not the schools of pharmacy as well as state boards be urged to give the Pharmaceutical Syllabus recently issued a little more than a casual glance? No school might be able to follow in every detail the work as there outlined, but if the syllabus were taken as a basis upon which to build, the curriculum would be much simplified.

In this matter of curriculum I dislike to admit that we are behind other professional schools, and even liberal arts colleges, where much more plasticity could be allowed than in professional schools. I claim that our course of study, being shorter and having more of the nature of an applied science, by just so much are we in greater need of a uniform curriculum than the liberal arts college. To the broadly educated man of so-called cultural attainments, who may be a writer, a lecturer, a minister or a critic of art, it is not of so much import whether he continue Greek or take up biology in his second year, but to the pharmacist, whose second year is probably his last, and whose course of study while not supposed to culminate in the State Board examination must nevertheless attain to that, it is of vital importance whether he spend several hours upon the study of anatomy or prescriptions.

If some kind genie were to grant me leave to express a hope through the fulfilment of which in the coming year my greatest desire for the good of the colleges of pharmacy might be accomplished, I should say, "Place in all of our schools a sound and uniform course of study." If by some good fortune I were allowed a second wish, it would be, "Band together; or mutual protection and common achievement all pharmacists in every State." If the wand were waved a third time, I should say, "Implant in the soul of every pharmacist a righteous desire to put into his profession the highest and best of himself, making it not alone a means of money-getting, but a true embodiment of his earnest purposes, part and parcel of himself. Let him be of this or that or the other faith or sect or cult, but let him regard his profession as his masterpiece, the truest reflection of himself that he can present to the world."

Respectfully, CHARLES W. JOHNSON,
Secretary of Section on Education and Legislation,
American Pharmaceutical Association.

Richmond, Va., May, 1910.

The Chair called for action upon this very able and comprehensive report, and on motion of Mr. Asher, seconded by Mr. Sayre, it was ordered received and referred for publication.

The Chair stated that the next thing on the program was a paper by Doctor Harvey W. Wiley, of Washington, on the subject of "Drug Legislation as an Educator," but unfortunately the author was not able to be present, though he had sent his paper, and he suggested that the paper be read by title and referred to the Publication Committee. On motion of Mr. Asher, seconded by Mr. Stewart, it was so ordered. The full text of said paper here follows:

DRUG LEGISLATION AS AN EDUCATOR.

H. W. WILEY, M. D.

In discussing the benefits of the control of drugs, thus securing greater purity and efficiency in their use and eliminating fraud and deception from commerce therein, little attention has been paid to another important feature of such legislation.
It is quite evident that a very marked effect has been produced by this legislation in the way of education. In the curricula of the pharmaceutical colleges as a result of such legislation, attention has been directed more particularly to instruction which will enable those who manufacture and deal in drugs to conform to the provisions of the Food and Drugs Act.

This instruction has taken two principal forms:

First, a more rigid chemical control of the raw materials as well as of the finished product; and second, a great extension of the use of the microscope as a means of detecting adulteration and debasement.

In at least one pharmaceutical school which has come under my notice the full time of one professor is devoted to microscopical instruction where before the enactment of the law such instruction was a mere incident to the course. It is evident that in this one line a tremendous impetus has been given in an educational way to the training of experts in higher grades and efficiency, not particularly for use in national and state service, but for practical use in the factory and in the pharmacy. The value of this improvement, or extension rather, of education has not been fully appreciated, and it will be several years before the full impress of this new education is felt in a practical way. It is evident, I think, that this impress will be reflected in a much higher grade of raw materials, both of those produced in this country and of those imported from foreign countries. In fact, this result has already been secured in a very marked degree, and the character of the imported crude drugs especially has been vastly improved under this, what may be called, enforced instruction.

These changes in a practical way in the drug trade are so evident that they need no further exposition. The incidental or collateral effects of improved education are, however, deserving of a word. This educational work has been carried on largely in the trade journals devoted to pharmacy. There is scarcely an issue of these trade journals which does not have something bearing upon this point. Particular attention is called to some low-grade drug, or one which falls short of perfection, as a warning to those engaged in the trade, or better still, scarcely an issue of any of these journals appears without some article of research, indicating further extension of our knowledge respecting the character of drugs or some improvement in their handling.

Attention has been continually called to the fact that refuse matter, sand, dirt, sticks, and other extraneous bodies, have no place even in the crude drugs of commerce, and the importance of this fact has gradually dawned on the trade and on the people. It does not pay to transport dirt and refuse matter and the education incident to the drug legislation has brought this fact prominently to the fore. It may be all right to use refuse matter at home where its character is well known, and where it can be administered in such a way as to avoid any injury, but when it comes
to transportation of a material, no matter what it is, the extending knowledge of the subject has shown that only good materials really pay for transportation. Again, through this same avenue, namely, the trade press, not only are the pharmacists throughout the country receiving a postgraduate course of practical value, but the reading of pharmaceutical trade papers is extending both to other professional men not actively engaged in the drug trade, and also to the laity. In other words, pharmaceutical journals are not read alone by pharmacists but often contain matters of intense public interest, largely due to the awakened conscience of the trade as a result of knowledge brought about directly, or indirectly, through drug legislation. This knowledge does not extend merely to composition and quality, but also to effect and use. It can do no possible harm to the pharmaceutical trade to have a wider knowledge of the character of drugs disseminated among the people; hence it is not unusual to see the daily journals contain articles on drugs, their methods of preparation, their places of growth, means of transportation, and results of administration. Thus to the people at large a very considerable knowledge of drugs and their uses is imparted as a result of the legislation and the enforcement of the law.

The publication of notices of judgment of cases tried in the United States courts is very wide. Many of these notices of judgment find their way not only into pharmaceutical papers, but into other trade journals and into the daily papers. It is remarkable how many newspapers, magazines and trade journals publish these notices. Every one of them is an education to the person reading it, and thus a very extensive education of the people has resulted as incidental to the enforcement of the legislation controlling commerce in drugs.

The above are merely outlines of the various methods of education which have been either energized or established by drug legislation. At this time in almost all the states drug and food legislation are going hand in hand, and there are numerous centers of activity of an educational character emanating not alone from the national government but from the various state governments. All of these centers of activity impart instruction, all command the attention of the public, and everywhere interest in their work is manifested. The same thing is happening in the drug trade that has already happened in agriculture. A quarter of a century ago the farmers' institute was a rather remarkable affair as compared with the farmers' institute of to-day. Either the speakers were not masters in any scientific way of their themes, or if they were, the people were wholly incapable of understanding what they said. At the present day it requires an expert, not only of wide knowledge but of accurate knowledge, to go before a farmers' institute and make an address. If he should make the least slip in his scientific statements there are dozens of farmers who would instantly recognize the error. The day is approaching when an expert in
the drug line can go before a public audience and speak on scientific matters connected with the drug trade and be fully understood and comprehended by the people he is addressing. It is thus seen that from many points of view drug legislation has resulted, not only in an extensive, but a most valuable education of the people.

The Chair here offered an opportunity to Mr. Remington, of Philadelphia, to present a paper on Synonyms, which he had prepared.

Mr. Remington said before he read this short paper he wanted to say that, while he had been a member of this Section, and a member of the Association, for many years, the papers read by the Chairman and Secretary were the best he had ever heard in any Section on their respective subjects, and he was only sorry that a larger number of members of the Association could not have been present to hear them.

Mr. Remington then proceeded to the presentation of his paper, stating that it was short, and intended to emphasize the subject of synonyms, which would come up next week in the Pharmacopœial Convention, and would occasion a good deal of solid thought:

SYNONYMS.

By Joseph P. Remington, Ph. M.

For forty years the Committee of Revision of the United States Pharmacopœia have steadily pursued the policy of discouraging the use of synonyms, and every decade a number of them were dropped. Notwithstanding this, however, synonyms have been kept alive by wholesale and retail druggists, manufacturers, and others who have not been in sympathy with the efforts of the Revision Committee, and hence there has been very little change in labels. But there is another reason which lies deeper. The people have become so accustomed to these synonyms which are in constant use that, no matter what efforts are made by authorities, the names laudanum, paregoric, Brown's mixture, cathartic pills, etc., etc., will probably always be used.

One can easily picture the consternation of a customer calling for paregoric and receiving a liquid in a bottle labeled, tinctura opii camphorata. No amount of explanation would probably thoroughly satisfy the anxious mother that she was not poisoning her darling boy.

Is it not time to recognize the real facts and, at the present time, a serious condition confronts us. The Food and Drugs Act requires that the labels of official articles shall conform to the Pharmacopœia tests for that article, but if a synonym does not appear in the Pharmacopœia, then there is a loop-hole to escape prosecution. Hyoscyamus would have to comply with the requirements of the official assay, but henbane can go scotfree.

There seems to be no other way to secure a rigid enforcement of the
SYNONYMS.

law than to introduce the synonyms, in some form, into the next Pharmacopœia. It would probably be better to insert these in a table in the appendix, and then in the Introductory Notices, in the Pharmacopœia, state that the same requirements and tests apply to the articles known as synonyms as to the articles described under the Latin titles or English names in the text of the book but, even if this is done, there is a loop-hole. Many of the crude drugs have half a dozen or more synonyms and, with a little ingenuity, the dishonest dealer can select some synonym which is obscure and not covered in the pharmacœial table.

This need not, however, prevent the introduction of synonyms in the least objectionable way in the Pharmacopœia, and it would serve to correct, in a material way, the abuse of synonyms.

The Chair invited discussion upon the paper just read.

Mr. Rusby said the question was one of great importance. Twenty years ago, when it was proposed to drop synonyms from Pharmacopœia, he had opposed it strenuously, but was defeated; and the last time when it was proposed to reinsert it he was very urgently in favor of it, but not in favor of putting them in the back part of the book, as was now proposed. He believed they should come in connection with the title, where the article was discussed; that it should be in connection with the main title, as in the Dispensatories. He thought the influence of the law, which made it necessary to put synonyms in the Pharmacopœia now, was proof that the necessity existed just as much before, for the safety of professional work. He thought the prospect of having more synonyms in the Pharmacopœia was a cause for congratulation.

Mr. Remington said he was glad to hear Mr. Rusby's views on this question, but in regard to crude drugs there were two ways of looking at the definition of "synonym:" one, that it was the equivalent of the article defined in the text, the other that it was a near-drug, or a near-preparation. He thought if the Pharmacopœia insisted on synonyms, they should be an equivalent synonym—an exact equivalent, and regarded as equivalent; otherwise, the door would be open to a lot of things which could not, in law, be regarded as equivalent.

Speaking further on this question, Mr. Rusby said that it was the business of the Pharmacœial Committee to study this subject, and then put these synonyms in the Pharmacopœia as they thought they ought to go. He said he had been surprised at the number of drugs imported through the port of New York and sold under names that were not to be found in the Pharmacœia or Dispensatories. This very state of things made it a matter of urgent necessity that the Pharmacœial Revision Committee should take up the subject of synonyms, study them, and state under what synonyms drugs should be recognized, and fix it once for all.

Mr. Remington said this was just the information he wanted; that he
knew Mr. Rusby had that knowledge and experience, and he wanted to
draw it out, so as to put in on record.

Mr. Asher, seconded by Mr. Sayre, moved to refer this paper to the
Committee on U. S. Pharmacopœial Revision.

The Chair stated that the motion was, that this paper be referred to the
Committee on U. S. Pharmacopœia, which had already reported to the
Scientific Section, the results of this paper to be embodied with their
recommendations.

And so the motion was put and carried.

The Chair stated he wished to interpolate in the program here some-
thing he had in mind at the time the program was issued, and then allow
a few minutes’ discussion of the subject, limiting it to not more than ten
minutes, in order that the time for presentation of papers might not be
too much encroached upon. The question of Pharmaceutical Syllabus
was the subject he referred to, and he said Mr. Rusby had kindly con-
sent to present it before the Section.

Mr. Rusby said this was not the time to discuss the Pharmaceutical
Syllabus, because that was set down for discussion to-morrow at a joint
session with the Boards of Pharmacy and the Conference of Pharmaceutical
Faculties. His purpose here was simply to present the matter before this
Section, which was one of the three bodies which had to do with the
adoption of the Syllabus, and the completion of it. He said it was a very
great pleasure for him to present this subject before the Section on Edu-
cation. He would not go into the history of the matter, involving the
action of the three bodies concerned in its production, and the generosity
of the New York Board of Pharmacy in voluntarily surrendering to the
Committee of Twenty-One its position of leadership in this movement.
The three bodies to whom it was now committed were the American Phar-
maceutical Association, through its Section on Education and Legislation;
the National Association of Boards of Pharmacy, and the American Con-
ference of Pharmaceutical Faculties. Each of these bodies was to be
represented by seven members on the Syllabus Committee, which would
be known as the Committee of Twenty-One on Pharmaceutical Syllabus.
Seven members had been appointed the night before by the Conference
of Faculties, and seven more this morning would be appointed by the
Association of Boards of Pharmacy; and then, at the noon session of the
American Pharmaceutical Association in this room, the seven members of
the committee from this body would be appointed.

Continuing, Mr. Rusby said he wanted especially to speak of the educa-
tional value of this Syllabus to the people who had made it. He had been
singularly interested in this question, but his interest from the beginning
had been more in the direction of the educational work the Syllabus would
do among the members of Boards of Pharmacy and the Faculties than
among the students. The right view of a subject was not always had at
first. Twenty years ago, he said, he went to the Pharmacopoeial Convention at Washington and urged that the Pharmacopoeia should recognize pharmaceutical assaying. At that time he was in a hopeless minority, but he did not believe there would be three people in the convention to-day who would favor giving up pharmaceutical assaying. At the last meeting of the Pharmacopoeial Convention an attempt to have the Pharmacopoeia say something about powdered drugs was voted down. Physiological assay was another subject. All these things must have a start, and when they start they have very few advocates.

Mr. Rusby said that there was a general feeling that the time allowed for physiology in the Syllabus was too great. His view was that it was not too great, but that the percentage was too great—the percentage of time allowed for physiology was out of proportion, that he would admit. But there was nothing in the Syllabus on the subject of physiology that was not absolutely essential to a proper understanding of the subject; and no student could study materia medica as taught by the colleges, and understand it, if he knew less physiology than was provided here. The trouble was, that, though the percentage might be too great, the total course was not enough.

Mr. Rusby said that there were subjects in the Syllabus that had never been dreamt of, and spoke of the general movement among the Faculties and Boards of Pharmacy in getting ready to use the Syllabus. He cited the case of physics and other studies to illustrate the range of the Syllabus in this respect. He also spoke of the microscopic examination of powdered drugs—the way in which the druggist gets nineteen-twentieths of drugs—and the fact that, whereas the custom had been to have one microscope do for a number of students, now a microscope was to be provided for each student.

He referred to the presence of politics in Boards of Pharmacy, and the many members who had been upon such Boards as the result of political influence, and who were not qualified for their work. He said that in the effort to conform to the requirements of the Syllabus some of the members would master it, and others would say, "It is no use; I am too old." Some would go on and others would drop out.

Referring to the claim that in certain foreign countries American pharmacists were but poorly regarded, Mr. Rusby asked the question why this was, and gave the answer that it was because the American pharmacists as a class were not the educated men they should be—that they had not the education of their class in other countries.

Mr. Rusby went on to say that he did not believe there had been as much progress made in any line of education in the history of the world as there has been made in the history of Pharmacy in the last ten years. It was simply marvelous. He said he happened to know personally a number of professors in colleges of pharmacy and the schools who were
now buying text books on physiology, so they would be prepared to meet the requirements of the Syllabus in this respect.

Referring to the statement made by Mr. Beal at the Conference of Faculties the night before, to the effect that this was only a tentative Syllabus, Mr. Rusby said that all recognized that there must be changes in it; that nobody approved of it as a whole, but it was common ground upon which all could come together for the time being. The idea was to try it out for five years, and then make desired changes.

Mr. Rusby concluded by saying that he would like to have a motion by some one that the general principles of the Syllabus be approved.

Thereupon, Mr. Sayre, seconded by Mr. Stewart, moved that the Section on Education and Legislation approve the general plan of Syllabus presented by the Committee of Twenty-one, and also the appointment of a committee of this Association to co-operate with the committee having general charge of its revision.

Carried.

The Chair said the next subject on the program was a paper on the Need of a Federal Poison Law, by L. F. Kebler.

Mr. Kebler read the following:

THE NEED OF A FEDERAL POISON LAW.

BY L. F. KEBLER,
Chief, Drug Division.

There are at present fifty-three separate and distinct law-making jurisdictions exclusive of municipalities, etc., within the United States, and it can readily be seen that if each jurisdiction makes laws differing materially from those enacted and enforced in other jurisdictions manufacturers and dealers will be much hampered and annoyed.

During the last few years I have frequently been asked questions in substance as follows: "Why is there not an effort made to have a federal poison law enacted so as to bring about uniformity in poison labels throughout the United States?" After listening to the arguments of these manufacturers and dealers I looked into the question and found conditions which would certainly not make for facility in trade.

For example, the Massachusetts law requires the word "poison" to be printed in large black letters upon red paper.

The same law prevails in the Philippine Islands.

The labels in general use for poisons in Florida, Georgia and Mississippi, are red upon white or white upon red, but morphine and the salts of same are required to be labeled on scarlet paper.

The law of California requires the label to be printed either red upon white paper or white upon red paper, and in addition prescribes that an antidote shall be adopted by the Board of Pharmacy, and such antidote and no other shall be the one indicated upon the label.
This is sufficient to indicate the present situation relative to poison labels from the manufacturer's or dealer's point of view.

Another point prominently brought forward is the fact that nearly all jurisdictions have some law requiring poisons and preparations containing same to bear a poison label. In many instances, however, the retailer is constantly violating the law, for the simple reason that he has no way of knowing and is not advised relative to the poisonous nature of certain commodities sent into interstate commerce.

I recently examined a preparation containing almost as much arsenic as Fowler's Solution, and in addition thereto the maximum amount of opium salable in the District of Columbia and other jurisdictions, yet there was nothing upon the label or the package to indicate that the product was poisonous in nature except the declaration of two grains of opium to the fluidounce, a quantity which is not in excess of the amount permitted to be sold without restriction or a poison label. From conditions obtaining at present the retailer has no intimation whatever relative to the presence of any arsenic in this preparation, and he is unknowingly induced to violate the local law almost daily. This is only an example.

Many poisonous mixtures are sent directly from the manufacturer to the consumer without warning the latter in any manner whatever relative to the poisonous nature and dangerous character of the compound. For example, it is not uncommon to send to the consumer direct lozenges, sugar-coated pills, tablets, etc., containing larger or smaller doses of strych- cine, arsenic, corrosive sublimate, etc., without indicating in any way to the consumer the fact that the said products are poisonous in any degree, with the result that proper care is often not exercised to protect others. The packages are not removed from the reach of children, who, obtaining possession of same, believe them to be candy, with the result that a life is lost. This is not a theoretical deduction, but an observed fact. There recently was brought to my attention a so-called asthma remedy sent directly into the home by a lumber dealer, who had acquired the prescription containing enough chloral hydrate in an ounce of the material to take the lives of two or more adult persons or the lives of half a dozen of children, and yet nothing appeared upon the label to indicate in any manner the poisonous or dangerous character of the contents of the bottle.

Another line of business is the sending of large quantities of poisonous and habit-forming agents by the so-called drug-addiction "treaters" directly to supposed habitues through express companies. There are at present about 30 of these institutions and in some instances their remedies contain large quantities of morphine sulphate, opium, chloral hydrate and smaller amounts of cannabis indica, heroin, codeine, cocaine, etc. One physician supplied a treatment to a supposed morphine addict which contained, according to his own statement, 22 grains of morphine to the fluid ounce. Another so-called "doctor," a reverend gentleman, supplied a
mixture containing on the average 14.2 grains of morphine sulphate to the ounce. In one system in vogue a series of bottles are used, for example, 10, 12 or 18, as the case may be. These bottles usually contain large quantities of morphine sulphate, opium, dionin, heroin, etc. In one instance, for example, each of the 10 bottles contains 2½ grains of dionin and 4 grains of morphine sulphate per fluid ounce. Each bottle holds about 4 ounces of fluid, which means that each package contains approximately 16 grains of morphine sulphate and about 10 grains of dionin. These bottles are all marked "first supply." In another instance 18 bottles are used, nearly all of which contain large amounts of morphine sulphate. In some cases the amount of morphine sulphate is so large that it is impossible to bring about a complete solution by the vehicle employed. A "shake label" is wanting. Unless great care is exercised in a case of this character by the patient consuming the mixture, he is liable to take the greater portion of the undissolved morphine sulphate in the last dose and may thus unwittingly terminate his life. I am led to the belief that this is not such a very rare outcome with mixtures of this character, and, as a rule, no one is left to tell of the conditions surrounding the death. In none of the cases set forth above is there any indication whatever relative to the poisonous nature of the contents of the various bottles.

An interesting but sad feature brought out during my investigation is the fact that the demands for these poisonous habit-forming agents is much greater in the states having stringent laws which are being enforced. This feature has been brought to my attention particularly in connection with the so-called drug-addiction treatments, the states mentioned most commonly being Virginia, Texas and California.

It is true there is some feeling to the effect that too promiscuous a use of the poison label is liable to make it so common as to be ignored by the consumer. There may be some basis for this contention but in my opinion this is a trivial feature compared with the situation set forth above. The red light is commonly and prominently displayed where known danger exists. It is true these danger signals are at times disregarded with disastrous results, but is this any argument to the effect that these harbingers of safety should be removed because they are so commonly used? I think this is poor logic. Give the public the benefit of the doubt at least. The question naturally arising is what would be a suitable law? There are at present a number of excellent state laws which could be used as models; for example, Virginia, Texas, California, the District of Columbia, etc.

The Chair called for action upon this very excellent paper, and said that no one was better qualified to express an opinion on this particular subject than Mr. Kebler, as he knew the conditions as they existed.
Mr. Cliffe, seconded by Mr. Remington moved to receive and refer to the Publication Committee.

Mr. Asher asked Mr. Kebler whether the Federal law or rule required a poison label on substances containing poison, and Mr. Kebler replied in the negative. Thereupon Mr. Asher suggested it would be wise for the Association to go on record as requesting a change of the law, so that a poison label would be required.

The Chair responding to this, said he thought it would be a wise action for the Section to take, and suggested that Mr. Asher draw up such a resolution and present it at the afternoon session.

Thereupon the motion to receive and refer the paper for publication was carried.

The Chair called for a paper by Mr. Hallberg, on the Federal Food and Drugs Act, and Mr. Hallberg presented his subject in extended verbal extract, the full text of his paper being as follows:

THE FEDERAL FOOD AND DRUGS ACT.

THE PRINCIPLE INVOLVED AND THE RELATION THERETO OF STATE LEGISLATION.

BY C. S. N. HALLBERG.

The Federal Food and Drugs Act has now been in force nearly four years.

Despite the fact that it is purely an interstate measure it has done much good and could have been of much greater benefit but for the unfamiliarity on the part of both legislators and laymen as to the distinction between limitations and functions of, Acts by the Congress and legislation by the States.

Here it is possible that the exemption provision as to drug standards in the Federal Act may be unobjectionable and that it was necessary in order to avoid any serious restriction on trade and industry. On the other hand it was exceedingly unfortunate that so many States should copy this exemption provision in the State Acts. The exemption was evidently the result of a compromise with the interests who insisted on being protected or they would defeat the passage of the Act. Others again are certain that the law is unconstitutional and that it will be so declared by the U. S. Supreme Court. In this connection it may be interesting to examine into how such a law comes within the scope of the Constitution of the U. S., so as to be subject to Act by the Congress.

The Constitution of the U. S. is not a complete scheme of government for the people of the United States but only a part and that only the smaller part of such a scheme. To fill out the outline the constitutions and the laws of the several states must be taken into account. These provide by far the greater part of the machinery of government, the security of life, liberty and property and the political rights of the citizens.
“We the people of the U. S. in order to form a more perfect union, establish justice and insure domestic tranquility, provide for the common defence, promote the general welfare and to secure the blessings of liberty to ourselves and our posterity, do ordain and establish this constitution for the United States of America.”

Sec. 8. Congress shall have power to lay and collect taxes, duties, imposts and excises, to pay debts and provide for the common defense and general welfare of the U. S. to regulate commerce with foreign nations and among the several states and with the Indian Tribes.

Amendments: Art. X. The powers not delegated to the U. S. by the constitution nor prohibited by it to the States, are reserved to the states respectively or to the people.

It is then under the broad principle of “to promote the general welfare” that the Congress received its power to legislate on such objects, as Food and Drugs, and utilizes its further power “to regulate commerce between foreign countries and the individual states,” as a means to that end.

Is there anything that concerns or promotes the general welfare any more than supervision of the quality of Food and Drugs and protection of the public against adulterations and fraud?

But in order to conform with the most literal construction of the Constitution the Act by Congress is limited to interstate commerce and does not propose to interfere with intra-state trade.

This is in accord with the genius of our form of government—the most vital and valuable principle—that each state for itself experiment in this kind of legislation so that through generous rivalry, the most perfect forms of law known to man may be the result for this great democratic republic.

Alas! It may be only a theory, but nevertheless this is the guiding principle as enunciated by Jefferson and the fathers of the republic. The responsibility is upon us through our respective legislatures to work out such problems. There is no other way since the powers of the Congress are limited to those few functions delegated to it by the States.

EXTRACTS FROM THE FOOD AND DRUGS ACT.

The following sections of the Act as applied to drugs require study:

Sec. VI. That the term “drug” as used in this Act, shall include all medicines and preparations recognized in the United States Pharmacopoeia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals. The term “food,” as used herein, shall include all articles used for food, drink, confectionery, or condiment by man or other animals, whether simple, mixed or compound.

Sec. VII. That for the purposes of this Act an article shall be deemed to be adulterated:

In case of drugs:

First. If, when a drug is sold under or by a name recognized in the United States Pharmacopoeia or National Formulary, it differs from the standard of strength, quality or purity, as determined by the test laid down in the United States Pharmacopoeia or National Formulary official at the time of investigation:
Provided. That no drug defined in the United States Pharmacopoeia or National Formulary shall be deemed to be adulterated under this provision if the standard of strength, quality or purity be plainly stated upon the bottle, box or other container thereof, although the standard may differ from that determined by the test laid down in the United States Pharmacopoeia or National Formulary.

Sec. VIII. That the term "misbranded," as used herein, shall apply to all drugs or articles of food, or articles which enter into the composition of food, the package or label of which shall bear any statement, design or device regarding such article, or the ingredients or substances contained therein which shall be false or misleading in any particular, and to any food or drug product which is falsely branded as to the State, Territory or country in which it is manufactured or produced.

Second. If the contents of the package as originally put up shall have been removed, in whole or in part, and other contents shall have been placed in such package, or if the package fail to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any such substances contained therein:

Regulation 7. Standards for Drugs. (Section 7.)

(a) A drug bearing a name recognized in the United States Pharmacopoeia or National Formulary, without any further statement respecting its character, shall be required to conform in strength, quality and purity to the standards prescribed or indicated for a drug of the same name recognized in the United States Pharmacopoeia or National Formulary, official at the time.

(b) A drug bearing a name recognized in the United States Pharmacopoeia or National Formulary, and branded to show a different standard of strength, quality or purity, shall not be regarded as adulterated if it conforms to its declared standard.

It will be observed that the provision leaving the standards of the U. S. P. and N. F. optional, places the responsibility of protecting these with the individual states and supplementary to the Federal Act each State Legislature should enact a law, where such is not already in force, requiring that when a drug is sold under the name or title of the U. S. P. it must conform to the requirements of identity, strength, purity and quality; not to declare for such standards, only to permit their debasement through exemption.

Yet more than twenty states have enacted drug laws with this exemption, thus vitiating the good accomplished during all the years that the adulterations section in the Pharmacy Law have been in operation. This declared it unlawful to sell any article under the name official in the U. S. P. if below the standard of strength, etc., therein contained. This principle is as old as the Pharmacopoeias themselves. It led to the adoption of the Pharmacopoeias as against the private dispensaries.

The practical results are that all that the manufacturers or wholesale druggist has to do in order to comply with the law is to affix to the label of the package of the drug the injunction "For technical purposes," "For Mechanical Use," "Commercial," etc. Thus in Chicago, where no drugs act is in force, the section of the Pharmacy Act not having been enforced for some years, the common chemicals, drugs and essential oils are labeled so as to conform with the Federal Act, as for example:

40
Sulphur— for technical purposes.
Muriate ammonia— for technical purposes.
Carbonate magnesia— for technical purposes.
Oil of rose— for technical purposes.
Magnesium sulphate— for technical purposes.
Calcium carbonate— technical.
Oil almonds— imitation.

The only reason for the existence of Food and Drugs Laws are that they are a protection to the public. In what manner is a law a protection to the public which permits the manufacturer or wholesale dealer to sell any kind of adulterated article—Epsom salts—for example, containing 30 per cent. of impurities of calcium chloride, etc., by simply attaching to the label the legend "for technical purposes." The only technical purpose for magnesium sulphate is in the making of such preparations as "blush of roses" for decorative facial effects.

Besides, the retail dealer does not affix this injunction on the label, and the buyer is not any wiser, but believes that if it bears the notorious guarantee legend, that it is a pure and safe medicine.

What a travesty on honest dealing; what a dastardly attempt to hoodwink the public, and what an act of vandalism on the dearest and highest prerogatives of pharmacy and its principles which distinguish its votaries as professional men!

The old principle, "caveat emptor," let the buyer beware, does not apply to drugs; but here the principle, "caveat venditor," let the seller beware.

The buyer is not responsible in buying drugs, but the seller is, and this is what distinguishes a profession from a trade—the professional man as a pharmacist, selling drugs against the man who is simply engaged in buying and selling and who assumes no responsibility, but places this entirely on his customer or patron while he hides under the "guarantee label."

Drugs when sold place responsibility on the seller, and he is, therefore, the one responsible for the identity, quality, purity and strength. He cannot shift this on the buyer, and be, therefore, commits a fraud when he knowingly sells a drug which is not of the standard required, since the buyer is not competent for himself to determine its quality.

All State Drugs Acts should therefore carefully avoid falling into the error of exemption of the Federal Act, but they should declare that all drugs sold for medicinal uses under the names recognized in the national standards must show reasonable conformity thereto.

University of Illinois, School of Pharmacy, Chicago, May 1, 1910.

Mr. Remington said he wanted to call attention to what he considered was an exceedingly valuable point that Mr. Hallberg had brought out very clearly, and that was, that the principle of "caveat emptor" should
not apply to medicine. In the case of medicines, particularly, the seller should beware what he sells.

On motion of Mr. Remington, Mr. Hallberg’s paper was ordered received and referred to the Publication Committee.

The next paper was one by Wilhelm Bodemann, entitled “So called Attempts to Improve Pharmacy Laws,” and Mr. Bodemann presented his subject as follows:

SO-CALLED ATTEMPTS TO IMPROVE PHARMACY LAWS.

WILHELM BODEMANN.

Do not improve your State law, or try to do so, if the improvement makes the law worse than it was. Law-making is a business by itself and requires practice, as much, if not more, than the Art of Pharmacy itself. What you try to attain is one thing, what you get quite another. Let me illustrate this point.

The A. Ph. A. discussed pharmacy law changes in 1906, and wanted the time service clause wiped out, wanted the requirements for R. P. (Registered Pharmacist) increased and for A. P. (Assistant Pharmacist) decreased. What did we get? The time service was retained and the required time of experience reduced from five to four years. The requirement for R. P. was not increased but lowered—so that any candidate with two years’ experience and two years’ college attendance can on proper examination become full R. P.

I have read the legislative reports of the A. Ph. A. for many years very carefully, and find that American Pharmacy, as represented in the A. Ph. A. has always unanimously insisted on four years’ of practical experience, outside of college attendance.

Again in 1908 we talked “change of the law.” This time the war cry was “increase of R. P. requirements—and lowering requirements of A. P.—but increase of A. P. privileges.” If, as claimed, an A. P. can take charge of a store for three, six, twelve or twenty-four months, then I ask, in all fairness, where does the difference between A. P. and R. P. come in? John Jones, R. P., can open a chain of stores, and after the R. P. has opened the store, let an A. P. run it—if the privileges of an A. P. are to be limitless.

In 1908 we talked “Diploma requisites,” and this lured even many of the staunch advocates of the Illinois Apprentice Law to back water and sacrifice this gem of the Illinois law to the popular clamor for college diploma requirements. I do earnestly hope and pray that the time may come when Illinois or all States can put college diploma on their banner of requirements for registration, but because I do want higher education I cannot approve of cutting the very foundation to a higher education away from under this desideratum. If you admit the rabble, the cripple, as our lamented Searby termed the incompetent, to the ranks of Pharmacy, how in the name of common sense and fair play can you insist on
diploma requisite when the very essence of a college diploma is good preliminary education? What prudent contractor would allow a twenty-five-story-high sky-scraper to be built on a cedar post foundation?

When the 1908 our Legislative Committee was instructed to draft a law for diploma requisite, it was found expedient not to bother the Legislature with a change, and, nothing was done. This by way of illustrating my assertion—don't try to improve the law of your State if the improvement makes your law worse.

Right here I desire to state my firm conviction that our laws do not need improvement nearly as badly as laws to improve the Boards enforcing such laws. A poorly enforced law is a farce, and I wish to illustrate this point also. The Illinois law provides for recommendation by the I. Ph. A. to the Governor for Board appointments. These recommendations are optional, gratuitous, but the law says "The Governor shall appoint." But the Governor does not do so; he puts the aforesaid recommendations into cold storage for two and three years, for political expediency, and when he gets busy, as he has done, pays no attention to aforesaid recommendations, and makes political appointments to please political ward heelers, and appoints men with commercial side lines.

I can imagine no greater injury to pharmacy in my State than political Boards, and law enforced by men with side lines. At present there is a great wave of centralization going through this land. I hope that the A. Ph. A. will "catch on" and boost the cry for a National Board of Health, and if you please, a National Board of Pharmacy. We have all read what the Committee on Medical Colleges reported—over 50 per cent. of the job lot worthless. The demand was fewer but better colleges of medicine, and I emphatically insist that this applies to schools and boards of pharmacy.

A National Board of Pharmacy would do away with the bane of the National Conference of Boards of Pharmacy, viz., exchange of certificates—it would at once elevate pharmacy by abolishment of political hack drivers acting as State Board members, discrediting enforcement of pharmacy laws by political consideration and commercial influences. The position of board member should be a position of honor, not darkened by lobbyists and actors. Dr. Edmund James of the great Illinois University, hailed so august a person as Supreme Court Justice Harlan over the coals, in Marquis of Queensbury style—for what? For appearing as a lobbyist in favor of a college from which he received a salary. A Supreme Court judge with a side line! This shows that we are living in a commercial age, and I earnestly beseech this great A. Ph. A., that you will do all in your power to centralize the governing authority of pharmacy boards. Politics are the curse of this country, and woe to pharmacy if the time ever comes when our States are in the clutches of that dragon, politics.
Gentlemen, if I had had more time, I would have been briefer, for the best of pleas or the best of orations is spoiled by longitude. Long speeches are generally long on words and short on ideas, and again I regret that I could not spend the time to be briefer, for I hope that I may not have preached in vain, like the prophet in the desert.

On motion of Mr. Hallberg, this paper was received and referred to the Publication Committee.

The Chair said the next paper on the program was one by Mr. Sayre, on the "Kansas Liquor Laws as they Affected Medicine and Pharmacy," and called on that gentleman to present his paper.

Mr. Sayre suggested that the paper be read by title only, and it was so ordered.

The full text of his paper here follows:

KANSAS LIQUOR LAWS AS THEY AFFECT MEDICINE AND PHARMACY.

L. E. SAYRE.

Discussion of the liquor laws of an individual state may seem to be too sectional to occupy the attention of a national body, such as this Association. Yet investigation of the efficiency of particular laws in certain localities is one of the surest methods of arriving at positive conclusions regarding the efficiency of different kinds of laws.

Kansas has for years been a much discussed example of a state with prohibitory laws. Criticism of the laws, favorable and adverse, has been made with various degrees of truthfulness and by persons with various degrees of familiarity with their execution.

This brief discussion of the laws, in their relation to druggists, is based on material from the office of the Attorney-General of Kansas, collected by the Assistant Attorney-General, Mr. John Marshall.

Kansas enacted her first prohibitory law in 1881. This law provided for the sale of intoxicating liquors by any druggist who might obtain a permit from the probate judge of his county to sell such intoxicating liquors for medical, mechanical and scientific purposes, upon the written or printed prescription of a practicing physician, who was regularly engaged in the practice of his profession as a business.

Under this law a large number of drug-stores having permits made arrangements with physicians by which thirsty individuals obtained the necessary prescriptions. This abuse of the law, especially by physicians, was very prevalent. A number of physicians throughout the state were prosecuted under this law for giving prescriptions when they had reason to believe that the person asking for the liquor did not need it for legitimate purposes, but desired to use it as a beverage.

In 1885 this law was repealed and another law enacted in its stead. The latter which, during the time in which it was enforced, bringing the
druggists of this state into such disrepute, has been known as the Druggists' Permit Law. It was amended somewhat in 1887, and again in 1903. Under this law a person who desired to obtain an intoxicating liquor for medical, mechanical or scientific purposes, signed and swore to an application for such liquor, and then procured the liquor from a druggist having a permit.

This law, also, was abused, but to a less extent than was the one giving druggists the power to sell upon the prescription of a physician. Under the law enacted in 1885 many persons who desired intoxicants for use as a beverage would sign applications, stating that they desired it for medical purposes, naming any disease which their imagination suggested. Colds and la grippe became amazingly prevalent. In many instances no oath was administered to the applicant. A number of drug-stores in the state were conducted for the primary purpose of selling intoxicants, the sale of drugs for medical use being a secondary consideration. The result was that any person who desired liquor for use as a beverage could obtain it from unscrupulous druggists. Although during the twenty years that this law was upon our statute books, a number of druggists were prosecuted and placed in jail, the great majority of the unscrupulous ones easily avoided legal interference.

On account of the general failure to prosecute and convict druggists who violated the law of 1885, that of 1909 was enacted. This law prohibits the sale of intoxicating liquors for any purpose whatever. There is no defense for a druggist who sells such liquor. If he sells, he violates the law; the result is that he does not sell.

Since the enactment of the present law, practically all drug-stores have gone out of business which were run under the old law, for the purpose of selling liquor for use as a beverage. The present law is probably better observed than any other ever enacted by the legislature for the restriction of the sale of intoxicants. There have been few prosecutions under the law of 1909, because they have been unnecessary. Those which have occurred have been, as a rule, successful.

This absolute prohibition of the sale of liquor for any purpose has been favorably received by the people of Kansas. There has been little criticism of it. Both physicians and druggists agree that it is operating with comparative success, and no hardships worked by the law have come to the attention of the prosecuting officers of the state.

In conclusion, it might be added that the present law causes considerable inconvenience in obtaining alcohol for scientific purposes, since it must be procured from outside the state. Most professional men affected, are magnanimous enough, however, to suffer such inconvenience for the sake of the good name of their profession.

The Chair stated that there was one item of business upon the morning's program which must be transacted before adjournment, and that was
the consideration of the report of the Committee on National and State Legislation referred to this Section at the second general session.* He said there were some recommendations in the report which he would ask Chairman Hilton, of the Committee, to state, in order that the Section might take prompt action, and report to the Association in general session.

Mr. Hilton said that the first recommendation was directed to the action taken at Los Angeles last year, where it was decided to concentrate the efforts of this Committee on National Legislation—to divide the subject into State and National Legislation, the Section on Education and Legislation to look after State legislative matters, while the Association's Committee on Legislation should be a committee on National legislation, and look after matters pertaining to National legislation only, thereby doing away with a multiplication of committees. This action, he said, had been adopted, but had not been carried out. He thought this was the only way for the Association to accomplish anything before Congress. His idea was that there should be one committee, composed of the most available men, to look after the subject of legislation before Congress, and present the views of this Association. He thought these views should be clear and definite, so the committee could present a solid front in all matters that affected the interests of the pharmacists of the United States.

President Rusby explained that the reason the Los Angeles action had not been carried out was because of a misunderstanding. He said that when he went to appoint the Committee on National and State Legislation, he remembered that there had been some question of this kind raised at Los Angeles, but he did not know the result, and did not know whether any definite action had been taken. He wrote to Secretary Caspari and asked him what action had been taken in regard to the matter, and had received a reply that he could not find any record of it in his minutes. When the Proceedings appeared, the matter was cleared up. But he had not the information at the time, and hence the mistake. He said there was no intention to vary from the instructions of the Association, and he had no doubt that it would be observed for the future.

The Chair stated that as a matter of fact, this Section had not dealt with the question of National Legislation at all, but complied with the spirit of the resolution passed.

Mr. Hilton said that he understood the attitude of the President, but wanted to clear the matter up for the future, so that the work might be conducted along the proper lines.

The Chair called for the next recommendation, and Mr. Hilton explained that this was in regard to the establishment of a Department of Public Health, and was to the effect that the Association should endeavor to have incorporated in that bill when it was considered by Congress some provision to provide for a Bureau of Pharmacy.

* See page 487.
The Chair stated that he would entertain a motion that this recommendation be accepted and referred back to the Association in general session for final action.

Mr. Hallberg said he thought the Chairman of the Committee on Legislation would be familiar with what had been done along that line. Some comment on the bill had been made in the April "Bulletin" to the effect that all sorts of bureaus were provided for, except one on pharmacy, and the bill should not receive the support of the pharmacists, and should not pass. He said a copy of this article was sent to the introducer of the bill, Senator Owen, of Oklahoma.

Mr. Hilton asked Mr. Hallberg if any action had been taken by his office, or himself, looking towards the preparation of any amendment along that line, and Mr. Hallberg replied in the negative.

Mr. Hilton said he thought some action should be taken. He knew nothing of such a letter having been received. He said the bill had not yet been considered by the House, but was still in the Senate, and the advocates of the bill had had a hearing, if he remembered correctly, and had made a very poor showing, and had injured the bill more than they had helped it. He said that they had ample opportunity to amend the bill, and his plan now was to take some definite steps towards amending the bill. The recommendation was, that an amendment should be prepared along that line.

The Chair said that, as he understood the recommendation, it was that the Section recommend to the general Association to prepare an amendment to the National Health Bill, providing for a Bureau of Pharmacy.

Mr. Stewart suggested that with this be coupled the request that it be referred to the Committee of One Hundred for the Advancement of Science, of which Professor Fish was Chairman. He said he had talked to Professor Fish on the subject recently, and he knew he would appreciate such reference very much.

The Chair stated that the motion was, then, that the Committee draw up an amendment and send it to the Committee of One Hundred for the Advancement of Science.

And the motion was so put and carried.

Mr. Hilton said the next recommendation was in regard to supporting any bill providing for the regulation of alcoholic beverages, as long as that bill made ample provision for the druggist's procuring his alcohol for use in manufacturing medicinal pharmaceutical preparations. He moved that the recommendation be adopted and referred to the Association in general session.

This motion was duly carried.

Mr. Hilton said that the next recommendation was in regard to a bill to regulate the manufacture and sale of smoking opium, advocating the support of such a measure.
On motion, this recommendation was adopted.

Mr. Hilton stated that the next recommendation was in reference to Federal control of the sale of narcotic drugs in interstate commerce, and the recommendation was that the Association support the Cullom Bill bearing on this question. He said this was written before any other bill was introduced in Congress, and he could not do otherwise than report in favor of the Cullom Bill. He said the Cullom Bill was a revenue measure, and as every one who was familiar with the subject of legislation knew, or should know, no revenue measure could originate in the Senate, that duty being conferred by the Constitution on the House of Representatives. The Committee on Finance in the Senate could not act on the Cullom Bill, but Congressman Foster, of Vermont, had introduced in the House of Representatives a bill that was very similar to the Cullom Bill—in fact, practically the same, with just the change of a few words; and that bill should be supported, provided there were a few modifications. He did not see the necessity of including in that bill a provision for prohibiting the sale in interstate commerce of cannabis indica, as he did not think any one had done any harm with that; and it might be well, also, to consider the advisability of eliminating coca leaves. He said he thought all the organizations engaged in the handling of drugs, especially the Wholesale Druggists' Association, had gone on record very clearly in opposition to that particular point in regard to cannabis indica and coca leaves, but they were willing to support any measure that regulated the sale in interstate commerce of habit-forming drugs. He thought the Association should say "habit-forming" drugs, and he did not think that, at the present time, coca leaves and cannabis indica were sufficiently used in this sense to be included in that list. He moved that the Association go on record in support of the Foster Bill, with certain modifications.

Mr. Hallberg said that he was opposed to any regulation of drugs on a tax or revenue basis, except as an interstate measure.

Mr. Hilton responded that this is what the bill provided.

Continuing, Mr. Hallberg protested vigorously against this proposition, of every dealer in every State of the Union having to go to the Internal Revenue Collector of his district, paying a dollar and "getting a tag" every year. He thought it was degrading to the profession of pharmacy—"this idea of being lined up with the rum-sellers and tobacco dealers." The revenue laws were established for the purpose of raising revenue, and this would be a mere incident of the law, and he thought this regulation could not be tolerated by pharmacists. If it was to be confined to interstate commerce, he had no objection. He was equally opposed to the Foster Bill, as it was along the same lines. Mr. Hallberg said he thought proper regulation on this subject could hardly be expected, unless there was established a National Department of Health, with a Bureau of Pharmacy provided for, "with men of our own selection, who understand this
business, and understand what the public ought to have in the way of pro-
tection, and also understand our rights and privileges in the matter." He
moved as a substitute that the recommendation be changed to the effect
that this Association approve of any proper regulation for the handling of
narcotic or habit-forming drugs in interstate commerce.

The Chair asked if the substitute was acceptable to the original mover,
and Mr. Hilton replied that he had no objection, if it was the will of the
Association. He could see no objection to the inclusion of this provision
in a revenue bill, where it would come under the control of the Revenue
Department. He reminded the members that this situation had been
brought about by the acts of certain pharmacists, in the promiscuous sale
of habit-forming drugs between the States, where the State laws prohibited
such sales within the State. This was true of a good many druggists, and
especially of the commission and supply houses, and there should be some
means by which these people could be reached, where the State laws could
not reach them. He did not care about the means; he was after results.

Mr. Hynson, referring to Mr. Hallberg's objection to having this matter
come under the revenue laws, said it did not seem to him at all accred-
ditable to pharmacy that it should be so. He had taken out a retail liquor
dealer's license for a great many years for the privilege of selling alcohol,
and he did not consider that it reflected on him in any way. He said he
understood the object was to get the splendid organization of the Internal
Revenue Department, "the best in the world," in control of the sale of
these drugs, and he was heartily in favor of it, and thought it would result
in the purification of the drug business from this evil.

The Chair asked Mr. Hallberg to state his motion again, and he said
that it was that the Section was in favor of such regulation in the sale of
narcotic and habit-forming drugs, so far as interstate commerce was con-
cerned.

This motion was seconded by Mr. Dittmeyer, of West Virginia, and
carried.

Mr. Hilton said there was one other recommendation in the report of
the committee that he thought should be taken up and considered care-
fully: That a bill had been introduced by Congressman Coudrey, provid-
ing that all drugs shipped in interstate commerce should be of the stand-
ard prescribed by the U. S. Pharmacopoeia or National Formulary; and
where there was no standard specified by either U. S. P. or N. F., giving
power to the Secretary of Agriculture to establish such standards. Mr.
Hilton said he thought the second end of that proposition needed no
argument; that if pharmacists could have standards established by the
United States government for anything for which there was no standard at
the present time, and these standards did not interfere with the U. S. P.
—which they would not, under the provisions of that bill—that they
should certainly accept it. The first proposition, however, compelling all
drugs entering into interstate commerce to be of the standard as prescribed by the U. S. Pharmacopoeia or National Formulary meant an amendment to the National Food and Drugs Act; that, as all knew, there was a provision in that act allowing a deviation from that standard, provided it was clearly and explicitly stated on the label what the standard was. He said his idea had been all along that the greatest mistake in the Food and Drugs Act was that provision which allowed drugs to enter interstate commerce of "any old" standard at all. It might be explicitly stated on the label what the drug was, but that did not prohibit that drug, after it went into trade, from being used by unscrupulous persons for the purpose of sophistication and adulteration. He said if it were possible to have fair, just, reasonable standards adopted by the U. S. P. and N. F., such as could be met in the ordinary conditions of supply for these drugs, then he was in favor of this proposition. But he thought this point should be carefully considered before the Association acted on it.

The Chair asked Mr. Hilton if he intended by his remarks to make a motion covering his ideas in this matter, and Mr. Hilton replied that he would now make a motion that the second clause of this bill, providing for the establishing of standards by the Secretary of Agriculture, where no standard was provided for in the U. S. P. or N. F., be approved, and that the first provision be supported, provided fair, reasonable and just standards were adopted, so that they could be met in the ordinary supply of these drugs.

Mr. Mayo suggested the separation of the two motions, and that all reference to the first proposition be eliminated, and that no action be taken on that at this time, as the standards of the Pharmacopoeia could not be changed just now.

Mr. Hilton then stated the effect of the motion in regard to empowering the Secretary of Agriculture to establish standards where such were not provided in the U. S. P. and N. F., and Mr. Stewart seconded the motion.

Mr. Raubenheimer called attention to the fact that, two years ago, the Association had placed itself on record as favoring the creation of such standards.

Mr. Rusby said that while it might be true that there was some such committee, it would be found, inevitably, that there would be drugs not included in that committee's report.

The vote on the motion as amended, limiting it solely to the approval of the proposition that the Secretary of Agriculture should have the right to establish standards, when none were provided in the U. S. Pharmacopoeia or National Formulary, was taken by division, with the result that the motion was adopted by a vote of 37 favoring the proposition to 25 against it.

The Chair declared the motion adopted.
The Chair stated that this concluded the consideration of the report of the committee, which would now be referred to the Association in general session.

The Chair called for the nomination of officers of the Section for the ensuing year as the final order of business, and Mr. Remington nominated for the office of Chairman, Mr. Charles W. Johnson, of Seattle, and for Secretary, W. J. Teeters, of Iowa. He explained that Chairman LaWall requested that his name should not be put in nomination, although it has been customary to renominate the Chairman to serve a second term.

The Chair called for nomination of Associates on the Committee, and Mr. Remington nominated Mr. J. W. Sturmer, of Lafayette, Indiana. Mr. Cliffe nominated John C. Wallace, of Newcastle, Pennsylvania. Mr. Mayo nominated Philip Asher, of New Orleans. Mr. C. Caspari, Jr., nominated H. P. Hynson, of Baltimore, but he declined. Mathias Noll, of Atchison, Kansas, was nominated by Mr. Sayre, but he likewise declined. Mr. England nominated W. L. Cliffe, of Philadelphia, but that gentleman withdrew his name from nomination.

Mr. Hallberg said he wanted to make a nomination for Secretary. He thought that the Secretary should be a member, and possibly Chairman, of the Committee on National Legislation, so as to concentrate the work in the hands of one person. He thought if the right man could be found to do this statistical work, where he would be right in touch with everything, and could furnish this valuable statistical report every year, it would be well to keep him in that position for, say, five years. He believed the retiring Chairman, Mr. LaWall, was the man for this place, and he, therefore, nominated him for the office of Secretary.

Mr. LaWall responded that he must respectfully, but firmly, decline this nomination.

The Chair stated that before entertaining a motion to adjourn and turn this session over to the general Association, he wanted to announce that the reassembling of the session would take place at 3 p. m. sharp, when a number of papers of importance would be read.

On motion, the Section then adjourned to 3 o'clock p. m.

SECOND SESSION—THURSDAY AFTERNOON, MAY 5, 1910.

Chairman LaWall called the second session of the Section on Education and Legislation to order at 3 o'clock p. m., and stated that the first order of business was the election of officers for the ensuing year. He called attention to the fact that there was as yet but one nominee for each of the offices to be filled, and said that, unless there were other nominations, he would sustain a motion to elect these gentlemen by acclamation.

Mr. Holzhauer, seconded by Mr. E. F. Cook, so moved, and the motion was put and carried.
The Chair declared that Charles W. Johnson, of Seattle, had been elected Chairman; W. J. Teeters, of Iowa, Secretary, and Messrs. J. W. Sturmer, of Lafayette, Indiana; John C. Wallace, of Newcastle, Pennsylvania, and Philip Asher, of New Orleans, Associates on the Committee.

The Chair stated that the Section had before it the report of a special committee appointed at the Los Angeles meeting last year, on the importation of opium and cannabis indica, to be presented at this time, and he would ask the Secretary to read it, together with the correspondence attached.

The Secretary read said report as follows:

Richmond, May 4.

To the Section on Education and Legislation of the American Pharmaceutical Association:

We, your committee on the resolutions presented by G. H. P. Lichthardt, have duly investigated and have been unable to find the conditions prevailing as described in the preamble and therefore, deem it inadvisable for the Association to take any further action at the time.

Respectfully,

E. G. Eberle,
Leonard A. Seltzer,
George F. Payne.

LICHTHARDT RESOLUTION.

WHEREAS, The National Government has very rightly safeguarded our people by prohibiting the importation of opium for illegitimate purposes; and

WHEREAS, It has been found that another narcotic and habit-forming drug, to wit, the various forms of cannabis indica as used in the far East as intoxicating agents, has been introduced to take the place of opium; and

WHEREAS, The American Pharmaceutical Association has ever opposed the importation, sale and indiscriminate use of all narcotics; be it

Resolved, That this Association request the National Government to pass such laws and regulations that would stop the practice of such importations into the United States of America.

G. H. P. Lichthardt.

The Chair called for action on the report just read, and Mr. Mayo, seconded by Mr. Ladish, moved that the report be adopted, and the motion prevailed.

The Chair next called for report of the Committee on Chairman’s Address, and asked Mr. Arny, of Cleveland, to take the chair while the report was being read.

Mr. McGill, of the committee, presented the report as follows:

REPORT OF COMMITTEE ON THE CHAIRMAN’S ADDRESS.

The Chairman of the Section on Education and Legislation has not in his address put forth certain propositions which call for action at this meeting, and of which the committee is expected to report approval or disapproval. But he has done as well in giving an excellent discussion of proper methods of teaching and the duties of the pharmacist with respect to keeping up with the progress of his profession and acting as an instruc-
tor of the public in regard to new pharmaceutical preparations, and warning the public against the use of such as are inefficient or injurious.

The practice of some druggists "in giving tacit endorsement to such preparations by allowing their names to be used in connection with advertising them" cannot be too severely condemned. "Unless the rank and file of pharmacists awaken to a sense of their responsibilities in such matters," the Chairman says, "there may come a fulfilment of the frequently expressed prophecy of a division of the members of the profession into two classes, one of tradesmen, whose energies shall be restricted to handing out what somebody else has put up, and the other of professional pharmacists in the true sense of the word, who shall enter into the heritage which has awaited them for many years."

The committee in agreeing with the Chairman only begs leave to add that such a division seems almost the only way of clearing up the present confusion in the methods and courses of pharmaceutical instruction in our schools and preserving the right and title of the pharmacist to equal standing with members of other professions.

The committee wishes to draw especial attention to the question raised by the Chairman, "whether it would not be advantageous to construct an educational system in pharmacy based upon a judicious plan in which electives are permitted." The special lines of work now open to pharmacists in chemistry, bacteriology, microscopy and the manufacture of pharmaceutical preparations almost demand the provision of different courses of study to prepare for them properly; and it may be seen by reference to catalogues that they have been introduced into a number of schools.

The address of the Chairman held the close attention of the audience, and the committee is confident that the expression of its own endorsement and commendation meets the approval of the members of the Section.

Respectfully submitted,

J. T. McGill,
A. B. Huested,
A. B. Lyons.

The Chair called for action on the report, and on motion of Mr. Stewart, seconded by Mr. Burge, it was ordered accepted, to take the usual course.

Chairman LaWall resumed the chair.

The Chair stated that the first formal paper for consideration of the Section was one on chemical laboratory courses, by Frank X. Moerk, of Philadelphia, which, in the absence of the author, would have to be read by title, under the rule. He said he wanted to present this paper to the Section for action, so that it might go through the proper channel.

On motion of Mr. Cliffe, seconded by Mr. Mayo, the paper was ordered received and referred to the Publication Committee, with the recommendation to publish in the Proceedings. The full text of said paper here follows:

LABORATORY COURSES IN CHEMISTRY.

BY FRANK X. MOERK.

In answer to a request made by your Chairman for a short paper on the above topic, the following has been prepared:

While chemistry is admittedly in the main a laboratory study, students must have some preliminary knowledge of chemistry, and should this be found lacking or deficient it becomes the duty of the teacher to remedy this condition.
For some years past methods of instruction have been in vogue by which the students are gradually introduced into the study of chemistry, that is to say that electro-chemical character, valence, formulas and reactions with their explanations, are taken up under the elements and their compounds; the results of this method, however, show that many students do not obtain a sufficient working knowledge of these fundamentally important points; the writer therefore is of the opinion that this part of the work should be given in oldtime allopathic doses, and that the student be compelled to master it by consistent application since there are but few tests and experiments which cannot be expressed in the form of reactions or equations. For the encouragement of the student stress should be placed upon the fact that the thousands of observations and investigations made during the past 125 years can be systematically arranged and studied in groups, and that this kind of study is an advantage which students of the present time have and of which they should avail themselves.

This theoretical part followed by a course of experiments illustrating the preparation and properties of the important elements and their compounds will lay a good foundation (1) for qualitative analysis, if the experiments include the usual analytical tests, and (2) for quantitative analysis if the experimental course includes the preparation of some chemicals using the reactions and molecular weights as the basis.

Qualitative analysis should be presented as a study involving, in the order of the frequency of application, (1) solubilities, (2) volatile or gaseous products or non-volatile residues and (3) formation of colored solutions. A proper development of the reasoning power of the student in explaining the different steps in the separation of groups will be of very great help in taking up quantitative analysis.

In taking up this last-mentioned branch the earnest student will realize his deficiencies in the first part of the plan outlined, because all quantitative work requires the thorough understanding of reactions and these in turn demand a knowledge of valence in constructing the formulas of reacting substances. The various branches of quantitative analysis will present an opportunity for discourses upon modern physical and chemical theories, as solution, ionization, precipitation, etc. The quantitative analysis of mixtures of inorganic salts in which the student formulates his own methods, using gravimetric, volumetric or gasometric methods or combinations of these, will afford splendid practice prior to taking up the analysis of inorganic industrial materials and products.

Organic Chemistry can be taken up in the same systematic manner:
Theoretical consideration of organic compounds.
Preparation of organic compounds.
Qualitative tests for the usual elements.
Class and individual reactions.
Melting, boiling and solidifying points.
Specific gravity.
Fractional distillation.
The use of refractometers and polariscopes.
Quantitative determination of the usual elements.
Determination of molecular weights.

This is then followed by the Analysis of Industrial Organic Compounds using the arrangement as given in Sadler’s Industrial Organic Analysis and “Bulletin” of Chemistry No. 107, Dep’t of Agriculture and the U. S. P., 8th Revision for official substances as in the assay of volatile oils, alkaloidal and resinous drugs; qualitative tests for alkaloids extracted in the assay processes should be made to establish their identity.

Toxicology including the determination of inorganic and organic poisons as well as the synthetics prescribed by the Food and Drug Law.

Finally the proximate analysis of organic mixtures can be taken up for consideration.

While many pages could be written by going into greater detail, the intention of your Chairman, I believe, has been met by this outline in which the subjects are taken up in logical sequence: it is possible in this arrangement to point out the importance and application of the earlier portions in the more advanced work.

The Chair stated that the next paper was one by George M. Beringer, on False Standards in Pharmaceutical Education.

Mr. Beringer presented his paper as follows:

**FALSE STANDARDS IN PHARMACEUTICAL EDUCATION.**

GEORGE M. BERINGER.

The student of pharmaceutical history cannot fail to note the course of pharmaceutical education in America. Prior to the establishment of the schools of pharmacy the education of an embryo-druggist consisted in the store experience or practical training acquired by serving an apprenticeship with some druggist or in the dispensary of a physician and the meager book instruction obtained by reading the few books on materia medica and chemistry found in the limited library of the preceptor. Until comparatively recent years, this was the foundation for the business possessed by a majority of those engaged in handling drugs. Many of these old apprentices gained a practical knowledge and a manual dexterity by actual experience with some of the processes of pharmacy that are now greatly neglected. Their training was that of the store entirely and the pendulum was swung to the extreme of the practical, and for years, even after the establishment of schools of pharmacy, this practical store experience was deemed the most essential part of the training of the pharmacist.

The only requirements for admission were integrity, strength, diligence
and perseverance and these were compensated by a meagre monetary consideration and a business and moral training under the personal supervision of the preceptor. Yet, in those early days the drug business was considered one of the high and honorable callings and an apothecary was quite as much respected in his community as is the pharmacist of to-day. The late William J. Jenks, of Philadelphia, once said to the writer: "The sons of the very best families in the city used to be brought to us as apprentices." Can we say that to-day?

As a direct result of state pharmacy laws and the efforts of the, by far too many, schools of pharmacy, there has been exerted an influence on the education of pharmacy and the practice of pharmacy which in some respects is deserving of our highest encomium and in other respects is deserving of severe condemnation. The writer is not a pessimist nor a stranger to the problems of the pharmacy and of pharmaceutical education of this day and generation, but believes that certain entangling alliances and pedantic efforts are leading pharmaceutical educators and examiners astray.

With the advent of an army of teachers to educate the rising generation of pharmacists there have been inaugurated marked changes in the curriculum, character of studies and methods of teaching. Many of these teachers are specialists and a majority are devoid of any experience whatever in the real problems of the drug store and its successful management. Naturally impractical and pedagogical views are evidenced in their work and utterance. With all honor to their high ideals and the laudable desire for advance which we believe actuates them, we cannot close our eyes to their impracticability and the fact that if their students attempted to put their teachings into practice 99 out of every 100 would fail in the hurly-burly of business that accompanies the drug store of to-day.

The attitude of these idealists is only too often that depicted so plainly by Professor Henry Van Dyke in the following abstract: "The academic atmosphere has its dangers, of which the greatest are a certain illusion of infallibility, a certain fever of intellectual jealousy, and a certain dry idolatry of schedules and programmes. But these infirmities hardly touch the mass of students, busy as they are nowadays with their athletics, their societies, their youthful pleasures. The few who are affected more seriously are usually cured by contact with the larger world. Most of the chronic cases occur among those who really never leave the preparatory institution, but pass from the class to the instructor's seat, and from that to the professorial chair, and so along the spiral, bounded ever by the same curve and steadily narrowing inward."

One of the falsities of the modern (?) system of pharmaceutic education is the deliberate, determined and persistent effort to minimize the value of drug-store training. Schedules and rosters are purposely so arranged as to occupy most of the time of the student and so preclude
store employment and crowd out the necessary practical experience that will be so vitally important to his future business success. It is the boast of many of these schools that their students devote the entire time to the laboratories and lecture rooms. It is amusing to note, however, that some of these, as if to apologize and make amends to the student, announce that they have installed a model store when he will be taught the art of handling and selling such wares as nursing bottles, food warmers, sick room requisites, etc., etc., according to the most modern and approved methods. Can such child's play in a toy drug store serve in any sense for the actual experience in the real store with its lessons in salesmanship and practical merchandising? Is not this present-day teaching swinging the pendulum to the other extreme of pedagogic theory?

I believe that the consensus of opinion among thoughtful pharmacists is that the capable clerk and successful proprietor is he who as a student receives a full measure of both store experience and collegiate education. He has "the mastery of the way to do things, the accomplishment that counts for future work."

One of the evil effects of the false educational atmosphere is too often exhibited in the perverted mentality and self-satisfying pride of the student. How many have met the embryo-pharmacist who could write an erudite chapter on the scientific methods of sterilizing an eye water but considers it beneath his dignity to keep the counter on which he compounds clean or to properly wash the utensils used in preparing the solution and the bottle to contain it. Such a drug clerk will have to unlearn much and learn the essentials of the calling that should have been first impressed and his affectation and pride will have to be rubbed out "by contact with that larger world" and perhaps he may then be ready to say with Emerson "One of the benefits of a college education is to show a boy its little avail."

It is the writer's purpose to particularly direct your attention to one of the requirements that within recent years has been promulgated by one of the state educational departments by which the registration of a college of pharmacy is dependent upon the number of hours devoted to instruction and it is further declared "how this must be divided into laboratory and recitation hours and that all instruction must be in day sessions prior to 6 p. m."

This appears to be a bald and bold attempt to establish time as a criterion and not quality or results. It manifestly gives undue prominence and consideration to what is only a minor element in estimating the real standing and value of any course of education. It appears to the writer as an exhibition of the big stick by pedagogues who have most likely exceeded the authority conveyed in the pre-requisite law. There are other elements of far greater importance than time in estimating the real standing of any educational institution. The location, proper construction,
Still more important is the ability of its teachers. We have all known professors who could impart more actual instruction in one hour than others could in six. Some lecturers gain and hold the attention of their audience and impress readily their facts, while others put the same audience to sleep or talk to empty benches. So that such a regulation would actually place a premium on incompetent teachers who can waste the time of students in either the laboratory or lecture room. Is not Dr. Van Dyke's type a better one: "I like the teacher who shows me not merely where he stands, but how he got there, and who encourages and equips me to find my own path through the mass of books and the tangled thickets of human opinion."

Not all students are in the same category mentally nor of the same temperament. Some can more readily grasp the facts than others. One prefers to learn from books, the other is impressed by lecture experiments, and another must personally perform the experiments before the facts are mentally stored. A teacher of many years' experience and of national reputation, in a recent letter to the writer says: "It is a grave question if in the modern demand for more laboratory instruction, whether we are not going too far in this direction, and it seems to me that much depends upon who is lecturing and giving the instruction. Good laboratory instruction gives better results than listening to a poor lecture. It is not the number of facts which a lecturer presents to the student which count, but it is the number which the student can retain, which makes for sound education."

The facility for acquiring knowledge cannot be regulated by rules and regulations issued by any state official, and time is certainly a useless factor. The teacher alone must be the one to decide how the truths can best be impressed upon each individual student and no state board should endeavor to decide for the teacher by arbitrary rules and division of time.

This regulation places all colleges of pharmacy and all of their students in the same class without considering the actual existing differences. Some schools, notably the departments of state universities, obtain their students young and fresh from the secondary or high schools, while in others the students are more mature and have usually spent some years since the preliminary education, in store work in acquiring the means and a proper foundation for a thorough and practical pharmaceutical education. The latter have a number of advantages over the former gained by actual contact with the drugs and chemicals of the processes and apparatus. Is it not reasonable to assume that a different kind of instruction is necessary for these two classes of students and that the former class will need much more of the elementary and laboratory training than the latter who have already largely acquired this by actual experience?
Further, should not due allowance be made for such store training? The amount of such allowance and the modification of the instruction due to such practical work should be left with each school as a local problem which under present conditions its faculty can best solve.

The writer is convinced that a definite period of actual store or manufacturing laboratory experience should be required as an entrance prerequisite by every college of pharmacy.

This meaningless and false standard for deciding the registration of a school of pharmacy, once promulgated was blindly adopted and followed by a number of the State Boards of Pharmacy. It is surprising how self-respecting men in quasi-official positions can hastily and thoughtlessly accept such a yoke of dictation.

It is certainly not fair to the applicant for registration that his knowledge and experience alone should not be the proper legal test of his fitness and determine his right to be licensed as a pharmacist. That these should be offset and nullified by an arbitrary ruling that his registration shall depend upon the number of hours of instruction that is now given by the college from which he is graduated, is certainly untenable. Can any one believe that this is the correct interpretation of the state pharmacy laws or that such a construction is based upon equity and would be sustained by judicial decision? Has not the time arrived when this ultra-dictatorial policy of the State Boards and Departments should be discontinued and pharmaceutical education be permitted to develop normally along correct lines?

The common error made by teachers and examiners is to imagine that their diploma signifies a finished pharmacist, instead, it is merely the admission to that great school of life itself.

The following words of Professor Henry Van Dyke in this respect are again peculiarly applicable: "Let us keep our colleges and universities true to their function, which is preparatory and not final. Let us not ask of them a yearly output of 'finished scholars.' The very phrase has a mortuary sound, like an epitaph. He who can learn no more, has not really learned anything. What we want is not finished scholars, but well-equipped learners; minds that can give and take; intellects not cast in a mould, but masters of a method; people who are ready to go on forward wisely towards a larger wisdom."

The Chair said he was sure the members had enjoyed listening to this very able paper, which was now open for discussion.

Mr. Hynson took sharp issue with Mr. Beringer, and said that, with the greatest respect to the author, he was compelled to say that this was the narrowest presentation of a subject he had ever heard him deliver. It was inconsistent with his general broad view of things, and he could not understand it. It was surprising to him that a man like Mr. Beringer
should not be better informed as to conditions. He thought his premises were altogether false. He thought if Mr. Beringer had soberly considered the conditions of his own surroundings when he first went into the drug business he could have counted on his fingers the really qualified pharmacists then in business that he knew, and he must have been driven to the conclusion that the percentage of good, qualified pharmacists at that time was immeasurably less than it was to-day. He thought that there could be no possible doubt of this proposition. Mr. Beringer seemed to have the idea that the world was going backwards, when everyone knew it was progressing rapidly, and if it progressed in one direction, it must necessarily in others. Personally, Mr. Hynson said he had great comfort in having found that there was a false halo thrown over "old times." He himself remembered practically every pharmacist in Baltimore, and a great many of their characteristics, when he went there a green, scared country boy, away back in 1875, looking for a position; and when he recalled the conditions in pharmacy in Baltimore at that time, and then thought of the army of really able, educated pharmacists of to-day, he thought it was one of the most glorious tributes that could be paid to the progress made in pharmacy. He regarded it as a serious mistake to place a boy of thirteen in a pharmacy, without any chance to acquire an education. He did not agree with Mr. Beringer's contention that he should be given four years in the drug-store and get his education afterwards. Continuing, Mr. Hynson said that there were always pathfinders in every century, who led the march of progress in the uplift of the masses, and the masses of one century stood where the pioneers of the previous century had stood. He thought Mr. Beringer's paper showed a false conception of the situation, and he believed that it was a great hindrance to the advancement of pharmacy to have a paper like this presented in this day and generation.

Mr. Ladish took exactly the opposite view from Mr. Hynson, and thought that gentleman misunderstood Mr. Beringer's paper. He commented the point Mr. Beringer had made so clear, that the tendency at present was to swing the pendulum too far the other way in the direction of theoretical education. Mr. Ladish referred to his twenty-odd years of experience in the active practice of pharmacy, and said he did not have the opportunity to avail himself of all advantages of the schools; but experience had shown him that the "finished product" that came out of the schools of pharmacy was sometimes lamentably weak in certain respects. He regarded Mr. Beringer's paper as standing for a continuance of the work along educational lines, but a warning not to lose sight of the fundamental principles of the drug business.

Mr. Huested said he had been very much interested in the paper presented, and endorsed what the author had said. He could not agree with Mr. Hynson in his criticism, as he believed that store experience was an absolute necessity in the make-up of the finished pharmacist. To illus-
trate his position, he told of an address made by Chauncey Depew to the graduating class of a certain university, in which he had reminded them that a theoretical education was the complement of a practical education, and said that of two engineers, one with college training on the scientific side of engineering, but without practical experience, the other brought up to practical experience only, he would rather trust his life to the practical man than to the theorist. And so with pharmacy, the practice of the art was not entirely scientific, but in its true sense a combination of science and experience. Mr. Beringer in his paper had pointed this out, and he agreed with him that the pendulum was swinging too far in the direction of pedagogic theory, and the tendency was to lose sight of the desirability and necessity of practical experience. He thought the paper was worthy of commendation and serious consideration.

Mr. Hays said the thought had occurred to him as Mr. Beringer was reading his paper that he must have gotten hold of a very poor clerk, with a diploma, and had an unsatisfactory experience.

Mr. Mason thought all must agree in large measure with what had been said about the necessity of practical training in the colleges of pharmacy; he did not think there could be any difference of opinion about that. But the discussion had been based on a misunderstanding of Mr. Beringer's paper. There must be store experience, but he thought there might be room for difference of opinion as to when the store experience should be had. The question was: Must it begin before the boy entered the college of pharmacy? Law, medical and theological students got practically no experience until they were graduated. The grievance he had against the old-line, independent colleges of pharmacy in this country, in their insistence upon store experience prior to their college education was this: That the boy entered upon his work at the tender age of ten or twelve or fourteen years, as a messenger boy—a sort of "roustabout." Probably in three cases out of four he found a better-paying place in a grocery or department-store and quit, while the boy who stuck got some four or five years of store experience, and then went to the college of pharmacy. He ventured to say that many of those present had been educated in this way, and they were a credit to the profession. But the almost universal fact was, that such boys were not proper subjects for education, and they did not get out of the college of pharmacy what they ought to get; and they were not equal, in his judgment, to the boy who had first gone through the grammar school, or perhaps had had four years of high school work, and then entered the college of pharmacy, and afterwards had the necessary store experience. He thought all must agree that in this way a better class of students could be had, and they would be a greater credit to the profession. If it was insisted always that the boy must have had store experience before entering the college of pharmacy, it meant that the pharmacist must often take an ill-prepared boy, and make him a messenger-boy, or put him at the soda fountain, to start with.
Mr. Eliel said he simply wanted to say in connection with this paper that, after an experience of some forty-nine years, first as an apprentice, then as a clerk in a drug store, and finally as proprietor of a drug store, he thoroughly agreed with the conclusions and deductions of Mr. Beringer in his paper. He agreed with Mr. Mason, however, that to take a boy of thirteen, deficient in preliminary education, and put him in a drug store as a "roustabout," and undertake to give him practical experience in a drug store previous to his entering a college of pharmacy, would be doing a great injustice to the pharmacist, and in the majority of cases a great wrong. Of course, there were exceptions to that rule—as in the case of men like Mr. Hynson, who had started in at the age of thirteen, and who had done fairly well.

Mr. Hynson responded to this that he was an "apt scholar."

Continuing, Mr. Eliel said that these exceptions were few and far between. The whole question of a prerequisite requirement before examination was one that had never been thrashed out thoroughly; but, in his experience, he had found that when he had a boy far enough along in school, after he had worked for some four or five years, he would make a good student in any school of pharmacy, and would be a credit to the profession when he got through. He said he had had experience with all kinds of boys, including the kind Mr. Mason had spoken of, and he had come to the conclusion years ago that he only wanted boys who would be a credit to the profession when they got through. He had had no trouble in getting boys of this type, and he did not think anybody would have, if they went about it in the right way. He concluded by saying that he was in thorough accord with the idea that Mr. Beringer intended to convey; he believed that the pendulum was swinging too far on the side of theoretical education.

Mr. Beringer, responding to the criticisms that had been made upon his paper, said he expected when he presented it to get a good "dressing-down." He said that Mr. Hynson had entirely misunderstood the premises on which his paper was based; that nowhere in that paper had he suggested that a boy of thirteen should be taken into the store, nowhere suggested that a boy without a preparatory education should be taken into a college of pharmacy. His argument, he said, was based on premises that he had not used. Neither was his paper based on the premises Mr. Hays had referred to. For thirty-four years and over, Mr. Beringer said, he had been practicing pharmacy, in daily contact with the mortar and pestle, and he was not ashamed of it. But he did not start in the work without a proper preliminary education, and he did not regret that he had practical familiarity with all classes of the pharmacist's work; he was proud of it. Personally, he did not believe that any college of pharmacy, no matter how scientifically or professionally educated the teacher was, could give that actual training he got from coming in contact with cus-
tomers in the store. There might be some questions about the proper time for having this store experience. He had expressed as his personal opinion that the young man should have a certain amount of store experience before he entered the college of pharmacy, and he was satisfied that such a young man would have a foundation for acquiring and understanding knowledge that he would not have otherwise. Speaking from the standpoint of the educator, Mr. Beringer said he had been in contact with the work of education for a good many years; that he had studied the subject, and was thoroughly in sympathy with higher education—as much so as any man in the room could be; but he did not believe in exaggerating the idea of mere time of study in the college of pharmacy—the number of hours—and making that the sole standard of efficiency. He thought that no man could argue that time alone was a factor to use in deciding the standing of any applicant for registration, nor for entering the school of pharmacy.

Mr. Meisner said that in all the years of his experience in the practical retail drug field he had never heard of a better exposition of, or a more clean-cut statement regarding, the real conditions as they existed than he had heard here in this paper of Mr. Beringer. He said he had found it necessary throughout his long business career to engage a great many men; and he had repeatedly engaged men who had simply had a grammar-school or high-school education, and had immediately entered upon the practical work of pharmacy; and he could say truthfully that those men who had simply gone through the schools of pharmacy were not in the same class with the men with the grammar-school or high-school education who had had the same number of years of practical experience in the drug-store. Therefore, he fully concurred with everything Mr. Beringer had said.

The Chair said if there was no further discussion of this subject, the paper would be referred to the Publication Committee, with recommendation to publish.

On motion of Mr. Ladish, duly seconded, it was so ordered.

The Chair called for the reading of what he said was one of the most valuable papers before the section, one on Patents and Trade Marks, by F. E. Stewart, of Philadelphia.

Mr. Stewart gave a verbal extract of his paper, the full text thereof being as follows:

**PATENTS AND TRADE MARKS IN THEIR RELATION TO PHARMACAL SCIENCE AND PRACTICE.**

*BY F. E. STEWART, M. D.*

The practice of medicine in all its branches is founded upon altruism. It is generally recognized that prevention is better than cure. The wonderful progress of preventive medicine in its fight against disease has
resulted in an enormous decrease in the number of cases of malaria, typhoid fever, diphtheria, smallpox, scarlet fever, yellow fever, cholera, plague, and many other diseases, from the treatment of which physicians derived an income. The discovery of the causes of diseases and their prevention has resulted in a corresponding decrease in the income of physicians and pharmacists.

Another cause for the decreased use of drugs in the treatment of disease is the increased knowledge and skill regarding their therapeutic application. The ancient shot-gun is giving way to the modern rifle in prescribing.

Greater knowledge and skill in the practice of the pharmacal arts is also playing an important part in decreasing the amount of drugs employed. As the knowledge of pharmacology increases the demand for experts in pharmacy and pharmacal therapy will increase; but drugs will no longer be used with the freedom characterizing medical practice in previous generations. The history of the past twenty-five years amply illustrates this fact.

The expert in pharmacognosy with his knowledge of botany and microscopy is teaching us how to select medicinal plants, how to grow them under proper conditions of climate and soil, and how to detect adulterations and sophistications. The expert pharmaceutical chemist is discovering new active principles, new methods of synthesis, new methods of preparation, and new methods of standardization. The expert physiologist is investigating the effects of medicines upon healthy tissues, that we may know more about their properties as therapeutic agents. The expert in therapydynamics is engaged in the study of the action of drugs on diseased tissues and is teaching us how to apply medicines in a more scientific manner. All of this knowledge is being utilized by clinicians in the treatment of the sick.

This advance in pharmacal science and practice is converting drugs into instruments of precision, but it is decreasing the amount of drugs sold, thereby proving injurious to the commercial drug business, but greatly benefiting the public health.

The question therefore confronts us, how are the practitioners of the pharmacal arts, depending as they do upon commerce in materia-medica products for their livelihood, to obtain the income necessary to continue their vocation under existing conditions? This is one of the problems we wish to consider.

Theoretically, the practice of the pharmacal arts is restricted by law to persons properly educated, trained and licensed. The practice of medicine in all its branches is supposed to be the prerogative of special classes of the community, set aside by the public and protected from unfair competition. This is considered essential to the welfare of the community. In a sense, therefore, medical and pharmacal practice are monopolies
granted to special classes in exchange for benefits conferred upon the public. The license to practice resembles in many respects grants known as patents given to authors and inventors.

ORIGIN OF PATENTS AND LICENSES.

It was from the practice of the sovereign in granting to a favorite, or as a reward for good service, a monopoly in the sale or manufacture of some particular class of goods, that the system of protecting inventions arose. The history of patent grants in England will serve as an illustration. The privilege was greatly abused by the English monarchs, grants being given for the merest pretext. Thus a grant of monopoly to sell playing cards was given because, "Divers subjects of able bodies, which might go to plough, did employ themselves in the art of making cards." A monopoly for the sale of starch was granted on the ground that "It would prevent wheat being wasted for the purpose." On such absurd and trivial grounds the rights of the people were given away by the ancient monarchs.

In the first Parliament of James the First, a Committee of Grievances was appointed. Numerous patents were brought before it and canceled, but the abuse was not corrected until the Statute of Monopolies was passed in 1623. This made all monopolies illegal, except such as might be granted by Parliament or were in respect to new inventions or manufactures. Licenses are lineal descendants of those old monopoly grants.

THE NATURE OF PATENT PRIVILEGES.

Many, perhaps the great majority of, inventors have incorrect ideas as to the nature of the patent privilege. Starting from false premises, they reason wrongly about various questions that arise, and they are never able to comprehend why laws read as they do or why the courts make certain constructions of the laws. A correct understanding of the nature of a patent grant and of the reasons upon which the patent law is based will do much to clear the difficulties that often beset inventors. The belief is very generally entertained that inventors have a natural right to their inventions, of the same kind as that given by the statute, irrespective of the actual passage of the law. Such is not the fact. (Traite des Brevets D'Invention: par C. Renouard. Phillips on Patents.) The right to the exclusive use of an invention is not a natural one—that is, pertaining to man in a state of nature; but, when it exists at all, it is a civil right, pertaining to man under the protection of the civil government.

An inventor has no right to his invention at common law. He has no right of property in it originally. The right which he derives is a creature of the statute and of grant, and is subject to certain conditions incorporated in the statute and in the grant. If to-day you should invent an art, a process, or a machine, you have no right at common law, nor any absolute right, to hold that for seven, ten, fourteen, or for any given num-
ber of years, against one who invents it to-morrow without any knowledge of your invention, and thus cut every one off from the right to do to-morrow what you have done to-day. There is no absolute or natural right at common law, that I, being the original and first inventor to-day, have to prevent you and everybody else from inventing and using to-morrow or next day the same thing.*

Another reason that militates against the theory that an inventor has any natural exclusive right to his invention, is that in a state of nature he would have no power to enforce his rights. In theory, his every neighbor is as strong as he, and combined they are much stronger. It may be urged that, as the inventor confers a benefit on his neighbor, by giving him knowledge of the invention, the neighbor is bound, in common justice, to make return therefor. This principle is no stronger than the one that the inventor is bound, in common justice to his fellow-men, to permit them an equal chance with himself to amass wealth, when doing so entails no injury on himself.

If an inventor has a natural exclusive right to his invention for one moment, he has it forever; and, if any limit of time can be set to such a right, only infinite wisdom is adequate to so delicate a task. To state the doctrine of natural right thus, is to show that it does not exist. The law has never recognized the doctrine of natural right; for it cannot recognize what does not exist.†

The policy of the patent law is, primarily, a selfish one on the part of the public, and only secondarily intended for the benefit of inventors, and then as a means to an end only. The Constitution of the United States gives Congress the power "to promote the progress of science and the useful arts, by securing, for limited times, to authors and inventors, the exclusive right to their respective writings and discoveries"; thus showing, in this fundamental legislation, that the object sought is the benefit accruing to the public.‡

The theory of the law is, that the promotion of science and the useful arts is of great benefit to society at large, and that such promotion can be attained by securing to inventors and authors, for limited times, the exclusive right to their inventions and writings. That such theory is correct, it is needless to say. It is almost self-evident, or at any rate readily susceptible of proof, that the magnificent material prosperity of the United States of America is directly traceable to wise patent laws and their kindly construction by the courts.

The patent laws promote the progress of the useful arts, in at least two ways: First, by stimulating inventors to constant and persistent effort, in

---

‡ Day vs. Union Rubber Co., 3 Blatch, 500; Kendall vs. Winsor, 21 Howard, 327.
the hope of producing some financially valuable invention; and, second, by protecting the investment of capital in the working and development of a new invention from interference and competition till the investment becomes remunerative.

A patent is a contract between the inventor and the Government representing the public at large. * The consideration from the inventor is the production of a new and useful thing, and the giving to the public of a full knowledge thereof by means of a proper application for a patent, whereby the public is enabled to practice the invention when the patent expires. The consideration from the Government is the grant of an exclusive right for a limited time, and this grant the Government protects and enforces through its courts.

According to Terrill, in his treatise on Patent Laws, "The theory upon which these laws rest is that it is to the interest of the community that persons should be induced to devote their time, energies, and resources to original investigation for the furtherance of science, the arts, and manufactures. This was recognized from the earliest period of time which can pretend to be described as civilized. It is to the advantage of the whole community that authors and inventors should be rewarded, and no measure of reward can be conceived more just or equitable, and bearing a closer relation to the benefit conferred by the particular individual, than to grant him the sole right to his writing or discovery for a limited period of time."

The statute enacts, "That, before any inventor or discoverer shall receive a patent for his invention or discovery, he shall make application therefor, in writing, to the Commissioner, and shall file in the Patent Office, a written description of the same, and of the manner and process of making, constructing, compounding, and using it, in such full, clear, concise and exact terms, as to enable any person skilled in the art or science to which it appertains, or with which it is most nearly connected, to make, construct, compound, and use the same."

SIMILARITY BETWEEN PATENT GRANT AND LICENSE TO PRACTICE MEDICINE AND PHARMACY.

The patent grant includes the exclusive right to practice the invention. The license includes the exclusive right to practice medicine and pharmacy. The patent grant is given in exchange for the publication of the invention. The license to practice is given in exchange for professional services. Let us therefore consider the character of this service. It is essential to the welfare of the community that the knowledge of preparing medicines and applying the same to the treatment of disease be conserved in scientific forms and thus protected from pretense and error. This re-

* Ransom vs. N. Y., 1 Fisher's Pat. Cases, 252.
requirement demands that each drug and preparation be provided with a name compatible with the accepted principles of scientific nomenclature and common to all languages; that the origin, nature, composition, and method of manufacturing drugs be published and readily accessible; that the various methods be submitted to comparative tests, and the best and cheapest adopted; that standards be established for the identity, quality, and strength of medicinal products, and that all manufacturers strictly conform thereto; that claims for therapeutic efficacy be submitted to clinical test to ascertain the comparative merits of various remedies; that methods be determined to prevent adulteration and fraudulent substitution; and, finally, that all the knowledge thus evolved shall be taught to medical and pharmaceutical students, and to the professions of medicine and pharmacy at large, by means of lectures, text-books, pharmacopeias, dispensaries, medical and pharmaceutical journals, and other literature.

In co-operating with the medical profession the introducers of new materia-medica products must wait for therapeutic verdicts before they are able to supply clinical information of a judicial character. As stated by Professor William H. Thompson, M. D., LL. D., in his discussion on diphtheria antitoxin at the New York Academy of Medicine,* the findings of a jury, whose members should be not only competent but so numerous and of such difference in locality and nationality that all personal or local influence can be safely left out of account.

DIFFERENCE BETWEEN PROFESSIONAL AND COMMERCIAL SERVICE.

It is necessary at this point to differentiate clearly between professional and commercial service. The learned professions, namely, theology, law and medicine, are organized as fraternities, in which each member by accepting his license to practice assumes certain obligations in relation to his profession. These obligations include the donation to science of the results of experience obtained by practicing his vocation. They also include the observance of certain rules for the guidance of the members of each profession in their relations with each other and towards the public at large. When codified, these rules are known as Codes of Ethics, and each profession has its own code. The Code of Ethics of the medical profession includes rules intended to protect the practitioners of medicine in their judicial position regarding the materia medica. It is held by many that no person can speak impartially in regard to an article which he has for sale, especially if he possesses a monopoly thereof and has invested capital in advertising its therapeutic value. The medical profession is therefore opposed to the monopoly of materia medica inventions, because such monopoly destroys the judicial position of the profession.

* Medical News, October 9, 1904.
As already stated, the therapeutic verdict about any alleged remedy must depend upon the findings of a jury whose members are competent to give such a verdict. If a member of the jury controls the sale of a materia medica product he is not in a position to speak with authority in relation to its therapeutic value, and he is therefore incompetent.

Some physicians even go so far as to claim that no person who has anything for sale can be truly professional, no matter whether or not he has a monopoly thereof. If this were true, it would become necessary to find some means of support for the pharmacal profession other than commerce in materia medica products.

Carried to its logical conclusion, such a claim would prevent the members of the professions from charging fees for their services. In fact, charging of fees was formerly considered unprofessional. Physicians and barristers did not charge fees for services rendered, but accepted in lieu thereof what were known as honorariums. The amount of such honorarium was determined not by the value set upon his services by the practitioners, but by the beneficiary's gratitude and ability to pay.

Now there cannot be two codes of ethics, one for physicians and another for pharmacists. The vocation of the pharmacist is part of medical practice, and pharmacists are under the same ethical obligations as physicians. If physicians prescribe nostrums this forces pharmacists to carry them in stock to meet the demand. Physicians who prescribe such products thereby force the pharmacists to violate their ethical obligations and become sales agents for a commercial business in materia-medica products carried on in opposition to professional usages. Under such circumstances the pharmacist cannot be a professional man and the fault is that of the medical profession. If a pharmacist doing a prescription business should in the morning throw out of stock all nostrums, before noon he would be obliged to renew his stock thereof to meet the demands of the medical profession itself. Thus the medical profession is primarily responsible for the invasion by the nostrum business of the field of pharmacal practice. Let us therefore consider the character of this invasion.

THE INVASION OF THE NOSTRUM BUSINESS.

In the study of this branch of our subject it is necessary at the outset to obtain a clear idea as to what is meant by "nostrums". The three characteristics of the nostrum business are secrecy, monopoly, and pretense. Materia medica products are not themselves animate beings capable of acting either for good or for evil. The question of ethics in this connection relates to the individuals, firms, or corporations having such products for sale.

In the issue for January 13, 1910, the editor of the official organ of the "National Association of Retail Druggists" ("N. A. R. D. Notes") thus classifies medicinal preparations.
1. Ethical Preparations.
2. Druggists' Own-Make Preparations.
3. Proprietaries.
5. Fakes.

According to the editor, an "ethical preparation" is one "whose entire composition is known, and can be prepared by any capable pharmacist"; the "druggists' own-make preparations" are those "common domestic remedies which almost every druggist prepares himself to meet a popular demand"; the "'proprietaries', erroneously called patents, are such as have, through merit, and by the price-protecting efforts of their manufacturers, become a recognized article of merchandise in most drug stores"; the "nostrums" are those "secret and semi-secret mixtures, either with or without coined names, about whose virtues such extravagant claims are generally made to the members of the medical profession or to the public"; the "fakes" include such compounds "as are intended more to defraud the public than anything else".

When it is considered that the same preparation may belong to any one of these classes, and that some of the so-called "ethical preparations" of the pharmacopœia were first introduced as secret nostrums, it at once becomes apparent that this classification is faulty because misleading. The question is in fact one of advertising. By advertising in this connection we mean recommending, whether such recommendation be spoken, or printed on a label, or published in a newspaper. Such recommending of medicines is a form of prescribing, and as this prescribing of nostrums is usually without diagnosis let us next consider the question of

**PRESCRIBING AT LONG RANGE AND WITHOUT DIAGNOSIS.**

A serious objection to the usual method of advertising medicines to the general public is that the system is one of prescribing or recommending medicines without diagnosis. This objection was pointed out by Judge Macfarland, of Pennsylvania, in his decision in the case of the Dr. Miles Medical Co. vs. the May Drug Co., as follows:

Its 'medical experts' are attempting to prescribe at long range. The attempt to diagnose cases of heart disease, for example, without a physical examination, cannot be too severely reprothed. We do not need to be told by medical authority, our own knowledge informs us that not only a careful examination, but great skill is needed to detect the numerous valvular and other diseases of the heart. Further, any intelligent, thoughtful person knows that many of the symptoms listed by the plaintiff are caused by other diseases or disorders. For one sick to diagnose his own case is the height of folly, yet this plaintiff advises the poor deluded victim to pass upon subjects often baffling the highest medical skill, to settle the nature of the disease, and then to take "Dr. Miles' Nervine", or "Heart Cure", or some other high sounding preparations of unknown ingredients, recommended in 'testimonials'.

The enormous business done by the proprietors of medicines and the serious menace
which it is to the lives and health of the public requires us to scrutinize carefully the
ground upon which the plaintiff stands, and as it has shown that it belongs to the repre-
hensible class, we decline to grant it a decree.

The history of the nostrum business will show where the names "patent" and "proprietary" medicines originated.

At first these preparations were known as secret nostrums and claimed to be inventions or discoveries in therapeutics. In process of time some of these secrets were betrayed or divulged, and it was then found that any one possessing the necessary knowledge and having obtained the same legitimately, has a perfect right to make and sell the same things. The next move was to patent these preparations under the provision allowing the patenting of compositions of matter. The Board of Examiners in Chief finally decided that "it was never intended that any composition of matter or mixture of simples should be the subject of monopoly. If rhubarb and senna, or calomel and jalap, were for the first time put together, he who should do it, whether regular practitioner or quack, would not be an inventor or discoverer under the law. If done by a physician, it would be only the exercise of ordinary professional skill; if by another, it would be but an ignorant jumble of things having supposed virtues and benefits to be obtained by the union of known drugs."*

The nostrum manufacturers next turned to the trade-mark law for protection. The following quotation taken from a "Petition of the Proprietors of and Dealers in Proprietary Medicines, including the Wholesale and Retail Dealers in Drugs, of the United States, described in their own language the method of procedure adopted by the nostrum manufacturers.

This Petition, which was read at the Annual Meeting of the Proprietary Association of America, St. Louis, October 17-20, 1898, is as follows:

The undersigned, representing the industries mentioned, hereby earnestly petition your Honorable House of Representatives and Senate of the United States, that the War Tax upon Proprietary Medicines may be promptly or speedily revoked, for the following potent and valid reasons.

Because it is founded upon entirely erroneous ideas as to the origin and value of the medicines the general or prevalent idea being that these medicines are mere nostrums, the outcome of ignorance or greed for gain; and that they are of no value as curatives for disease and are deserving of no legal recognition.

WHEREAS, The real fact is that they, to a very large and almost universal extent, are the best and most successful prescriptions of our most advanced and successful physician. The story is simple. The physician and the more eminent he may be the more likely this result is to happen, sends his prescription to his druggist, who carefully prepares and sends it to the patient; this is followed by others and others, all made of the same ingredients and the same proportions, and they are largely or even eminently successful. The druggist is alive to this—he knows from his own observations that he has in hand a cure for a certain definite form of disease, and gives it a name and launches it upon the public as a remedy for a certain form of disease."

* Caffall MS., Vol. 18, page 322.
PROTEST OF THE AMERICAN PHARMACEUTICAL ASSOCIATION.

The American Pharmaceutical Association protested against this system of business, by which the prescriptions of physicians entrusted to pharmacists are unfairly appropriated and launched upon the public as specifics for diseases. It most emphatically protested against the above statements of the secret nostrum manufacturers as unjust and damaging to the reputation of the pharmaceutical profession. There is in fact no drug which may be truly described as a specific or cure for any disease. Furthermore, the highest medical skill is required to diagnose each disease and to recognize its various stages as they develop, and no prescription will answer the same requirements of all the different stages of the same disease. When a medicine, whether it be the prescription of a reputable physician or not, is given a name and launched on the public as a specific or cure, when it is not, the person so doing is guilty of a moral wrong to the community and prohibitive or restrictive laws have been passed to control the secret nostrum business in such countries as France, Germany, Austria-Hungary, Japan, Brazil, Argentina, etc. The public should have at least the opportunity of knowing the medical ingredients and their percentage composition of every agent used for the prevention and treatment of disease, so that the people may be protected from the machinations of quackery.

It is admitted by the "Proprietary Association" in the above quotation that so-called "patent medicines" are usually not new things, and the only invention about them is that of their names. When it is taken into consideration that no one except their manufacturers knows the true composition of these nostrums, the absurdity of claiming that the names given them are trade-marks used for the purpose of distinguishing between brands of well-known prescriptions is apparent.

Again, as the claims made for these nostrums regarding their therapeutic value are not generally justified by the fact, it is evident that their manufacturers, when they make false representations in regard to these prescriptions, cannot come into court with clean hands to defend their alleged trade-marks. The burden of proofs must needs fall upon the advertisers of such claims, and proof cannot be forthcoming unless the true composition of their medicines is made known.*

"DRUGGIST'S OWN-MAKE PREPARATIONS."

What is the difference between "druggists' own-make preparations" and "nostrums"? That depends upon whether or not they partake of the characteristics of nostrums. As before stated, the characteristics of the nostrum business are secrecy, monopoly and pretense. The pharmacist

who pretends that his secret-formula, monopolized medicine is a specific or cure is just as much of a nostrum manufacturer as the unlicensed practitioner conducting his business at wholesale and advertising in the newspapers and magazines. Prescribing at short range without diagnosis is just as wrong in principle as prescribing at long range by nostrum-manufacturing houses. Any physician can relate incidents to corroborate this statement. A young man suffering with incipient phthisis went to the druggist, who prescribed a cough cure of his "own make." After fooling away about a year of precious time, the young man's condition was discovered by his physician, and he is now a charge of the State in a sanitarium for consumptives. This is merely one of thousands of cases.

It is admitted that a field for "druggist's own-make preparations" does exist, and that this field is perfectly legitimate. There are times when the physician's services cannot be secured and people are forced to resort to self-medication. The druggists should supply medicines to meet this demand, but they should not be guilty of prescribing without diagnosis. Preparations intended for self-medication should be provided with the formula and with as full information as circumstances will permit, including a list of diseases for the treatment of which they are intended, and proper directions for their use. But this field is limited to a narrow range of cases. The field should not be left to the nostrum manufacturers. The subject of domestic medicine should be considered jointly by the medical and pharmaceutical professions, and the boundaries of this field should be clearly defined. Physicians and pharmacists should cooperate in teaching the people how to use medicines in the proper manner.

**METHOD SUGGESTED BY THE SUPREME COURT FOR CHECKING THE NOSTRUM INVASION.**

The Supreme Court of the United States suggested an effectual method of checking the nostrum invasion, in its decision in the case of Worden vs. the California Fig Syrup Company, No. 35, October Term, 1902. The following quotation is taken from this decision:

Most, if not all, the States of this Union have enactments forbidding and making penal the practice of medicine by persons who have not gone through a course of appropriate study and obtained a license from a board of examiners; and there is similar legislation in respect to pharmacists. And it would seem to be inconsistent and to defeat such salutary laws, if medical preparations, often and usually containing powerful and poisonous drugs, are permitted to be widely advertised and sold to all who are willing to purchase. Laws might properly be passed limiting and controlling such traffic by restraining retail dealers from selling such medicinal preparations, except when prescribed by regular medical practitioners.

It is manifest that the legislation suggested by the Supreme Court would force all persons desiring to recommend or prescribe medicines, either as manufacturing houses or as retail druggists, to go through a course of ap-
propriate study and obtain a license from a board of examiners. This would create in this country a class of practitioners similar to the English apothecaries, who are not only licensed to practice the pharmacal arts but are also licensed to practice pharmacotherapy. In this way the legitimate demand of the public for materia medica products for self-medication, and for proper advice regarding the use of the same, is supplied.

THE TRADE MARK QUESTION.

It is axiomatic that "No one can claim protection for the exclusive use of a trade-mark or trade name which would practically give him a monopoly in the sale of any goods other than those produced or made by himself. If he could, the public would be injured rather than protected, for competition would be destroyed. Nor can a generic name, or a name merely descriptive of an article of trade, of its qualities, ingredients, or characteristics, be employed as a trade-mark, and the exclusive use of it be entitled to protection." *

“When an article is made that was theretofore unknown, it must be christened with a name by which it can be recognized and dealt in, and the name thus given it becomes public property, and all who deal in the article have a right to designate it by the name by which alone it is recognizable.” †

The following statement made by the Honorable Benjamin Butterworth, Chairman of the House Committee on Patents, is of value in this connection. After listening to a debate by the Committee on this subject, he turned to the Associated Press Reporter present, and said that “While the House Committee on Patents has no right to act as an interpreter of the law, that being the function of the Supreme Court of the United States, yet, as individuals, they had a right to an opinion. It was the opinion of the Committee, after listening to the evidence presented to it by the Delaware State Pharmaceutical Society, that

(1) The registration of an alleged trade-mark does not make it valid. Registration is merely to give notice that the thing registered is claimed as a trade-mark. The validity of the claim can only be settled by the courts.

(2) The use of a trade-mark in no way restricts the free use by others of the article of merchandise to which it is affixed. It confers on the user no privilege to the exclusive use of an invention of the kind conferred by the patent law, otherwise we should have the anomaly of laws diametrically opposing one another. The patent law grants the inventor the exclusive use of his invention for a limited time, and then only on the publication of exact knowledge of the invention whereby the public may manufacture it when the patent expires, by a proper application for a patent. The use of a trade-mark, on the contrary, is unlimited in duration, and no publication is required when it is used on an invention.

(3) The public has a perfect right to manufacture and sell any article of commerce

* Canal Co. vs. Clark, 13 Wall, 323.
not patented, and to do so under its proper or generic name whether a trade-mark is used in connection with the article or not. For this reason, the courts hold that names describing the article cannot be used as trade-marks on the article they describe. Otherwise the use of trade-marks would be a hindrance to competition, while the proper use of trade-marks promotes competition by distinguishing between one brand of an article and another brand of the same article, thus stimulating manufacturers to improvement in processes and methods of manufacture for the purpose of excelling each other in producing the same article of better quality or at a lower price."

As stated by the Court in the Celluloid Case, "When a name is coined by one who uses it as a trade-mark upon a particular article, if that name is originally a lawful trade-mark, its subsequent adoption by the public as a common apppellative cannot take away the right already acquired." *

But when an inventor says, "I have invented a new kind of thing," and then coins a word to distinguish it, the coined word becomes at once the title of the thing, and, therefore, is not a lawful trade-mark, for it is self-evident that it can no longer serve the function of a trade-mark to distinguish one brand from another brand of the same article, but becomes a name to distinguish one kind of a thing from another.

It is believed by many that when a person invents a name he can have it patented or copyrighted, and thereby secure an ownership in the name itself. This, however, is an error. As stated in Circular No. 19, issued by the Librarian of Congress, Copyright Office, Washington, D. C., "The Copyright Laws contain no provision under which protection can be obtained upon a mere name or title. Entry cannot therefore be made in the Copyright Office for coined names; names of articles of manufacture; names of games or puzzles; names of substances; names of products, or names of medicines."

The manufacturers of antipyrin, phenacetin and many other German synthetics, have registred these names in the Patent Office as trade-marks, with the view of maintaining their monopoly after the expiration of the patents on the products. If the claims of the manufacturers had been sustained by the courts, then these names could have been held for all time as private property, and the monopoly created by patents on products continued for an indefinite time. The decision of the United States Supreme Court in the Singer Sewing Machine Case, in 1895, prevented such monopoly. The decision reads as follows:

The results, then, of the American, the English, and the French doctrine universally upheld is this, that where, during the life of a monopoly created by patent, a name, whether it be arbitrary or be that of the inventor, has become, by his consent, either express or tacit, the identifying and generic name of the thing patented, this name passes to the public with the cessation of the monopoly which the patent created. Where another avails himself of this public dedication to make the machine and use the generic designation, he can do so in all forms, with the fullest liberty, by affixing such name to

the machine, by referring to it in advertisements, and by other means, subject, however, to the condition that the name must be so used as not to deprive others of their rights or to deceive the public, and therefore that the name must be accompanied with such indications that the thing manufactured is the work of the one making it, as will unmistakably inform the public of that fact.

DIFFERENCE BETWEEN PRODUCT AND BRAND.

It is important to distinguish between products and brands. As pointed out, each new materia medica product should be impartially discussed by professional societies and press. This is impracticable when the product is monopolized. Physicians hesitate to report, fearing reprisals on the part of the manufacturers if reports are adverse, or loss of professional reputation, if favorable. Products should therefore be free to science and commerce, to permit their discussion without fear or favor.

Brands and brand names, on the contrary, should be controlled by the manufacturers. Every brand should be so labeled as to permit of its ready identification, so that the manufacturer may be held responsible for its character, quality, and strength.

Brands may be protected by labels or trade-marks. When the identity of a product is apparent, it is not necessary that the name of the product should appear on the label. It is not necessary to label a ham, as such, for everybody recognizes the identity of the product. The brand mark serves to distinguish the source or origin of the ham, and nothing else is required. But when a new materia medica product is placed on the market, it is necessary to label it with a name by which it can be readily identified and dealt in. And in addition to the name of the product, the name of the manufacturer should appear on the label to permit identification of the brand.

Instead of the manufacturer's name a pseudonym or nom de plume may be employed to designate the brand. We have "York Mills" Linen, "Eagle Brand" condensed milk, etc. Sometimes the name of the manufacturer, and the brand name appear on the same label, as in the case of condensed milk.

Some manufacturers conceal the identity of the products and use fanciful names as labels, claiming such names as trade-marks, brand names, or word-marks. Hexamethylenamine was placed on the market under various names, as "Urotropine," "Cystogen," "Formin," etc. Each manufacturer evidently intended to mislead the profession by giving the impression that these names indicated different products, forgetting that names thus used are either descriptive or deceptive. If descriptive, the names are not trade-marks; if deceptive, those who claim them as trade-marks cannot go into court with clean hands to defend their claims.

When a materia medica product is provided with two names on its label, one claimed as the name of the product and the other as the name of the brand, the question at once arises whether the latter is in fact a
brand name or a synonym. This is a very important question and one requiring the most earnest consideration by physicians, pharmacists, and manufacturers. If the names are synonymous, then the pharmacist is justified in dispensing any brand he has in stock, no matter what name is used by the physician in prescribing. If, on the contrary, the name claimed as a trade-mark is recognized as such by the medical profession, and physicians intend to specify brands, then pharmacists who do not dispense the brand specified are guilty of fraudulent substitution.

It is fair to assume that as a rule pharmacists are honest and conscientious in their practice. It is probable that most pharmacists in our large cities are graduates of pharmaceutical colleges and are thoroughly competent to practice their art. But pharmacy, like every other vocation, has its black-sheep, and physicians should therefore either discriminate in favor of those pharmacists who are known to be both conscientious and competent, or should specify the brand of some manufacturer known to have the necessary facilities for maintaining proper standards.

What is needed is a profession of pharmacy; viz., an organization of professional pharmacists, guided by a properly enforced code of ethics, and working in co-operation with the medical profession, of which pharmacy is such an important branch.

PROTECTION OF BRANDS BY PROCESS PATENTS.

In most foreign countries patents are not allowed for materia medica inventions, but patents on processes are permitted. In Germany, for example, patents are not allowed for "inventions relating to articles of food, whether for nourishment or for enjoyment, and medicines, as also substances prepared by chemical processes, in so far as the inventions do not relate to definite process for the preparation thereof."

"If the invention relates to a process for the production of a new substance, all substances of like nature are considered as having been made by the patented process until proof to the contrary is given."

Some of the evils of our product patent system are well illustrated by the "Adrenalin" patent now under litigation. Not only had von Führth and Dr. John Abel demonstrated many of the properties of the adrenal secretion and published methods of preparation, but Oliver and Scharfer had worked out the physiologic action of this substance and indicated its usefulness in medicine. The methods of preparation were improved upon and patented by the well-known Japanese chemist, Takamine, to whom was also granted a product patent. Basing his claim upon this product patent, the manufacturer who now controls the Takamine patents is attempting to maintain for seventeen years a monopoly of all adrenal preparations. Progress in science and the useful arts is hindered, not promoted, by such a system.
“RESOLUTION AT RICHMOND.”

Students of medical history are familiar with the effort made at the meeting of the American Medical Association at Richmond, Virginia, in 1881, to define the position of the medical profession on the subject of patents and trade-marks. The resolution is as follows:

Resolved, That the spirit of the code of ethics forbids a physician from prescribing a remedy controlled by a patent, copyright or trade-mark. This, however, shall except a patent upon a process of manufacture or machinery, provided said patent be not used to prevent legitimate competition; and shall also except the use of a trade-mark used to designate a brand of manufacture, provided the article so marked be accompanied by working formulae, duly sworn to; and also by a technical, scientific name under which any one can compete in manufacture of the same.

This resolution was referred to the Judicial Council and turned down by Dr. N. S. Davis, the founder of the American Medical Association, on the ground that the endorsement by the medical profession of patents in any form was contrary to ethics. Since those days the Association has been reorganized, and it now stands in favor of patents on materia medica products.

CONCLUSION.

Finally, I wish to emphasize strongly the fact that I am not attempting to tear down the patent system or the trade-mark system. On the contrary, this paper is intended to be constructive, not destructive. Its object is to aid in building up the ideal taught by the colleges of pharmacy; namely, that pharmacy is—or should be—a profession, organized in accordance with professional or fraternal principles, having its code of ethics in which are given rules for the guidance of pharmacists in their relations with each other, the medical profession and the public.

We must know just where the pharmacists stand as a profession before we as a medical profession are in a position to endorse the vocation of pharmacy as practiced in this country. If it is to be a nostrum business, carried on as a commercial business having as its primary object the making of money by methods which are detrimental to the public welfare, we must know it and be guided accordingly. If it is to be a profession, working in harmony with the medical profession for the prevention of disease and the relief and cure of the sick, we as a medical profession should take the profession of pharmacy under our fostering care and do all in our power as physicians to co-operate therewith.

Whether the preparation of medicines is conducted at retail by the individual druggists or is carried on at wholesale by the great manufacturing houses is a consideration secondary to the one great object in view. The retail druggists should occupy a prominent position in this country as manufacturers and distributors of medicines. To the extent that they do not possess facilities to do their own manufacturing, this work should be done
by the large manufacturing houses, with their scientific departments, aided by capital and managed by level-headed business men.

But as a medical profession we cannot endorse materia medica monopoly, whether obtained by secrecy, product patents, or misuse of trade-marks. We should not consent to any plan for building up a great commercial business in drugs, depending upon misleading advertisements skilfully worded to deceive the medical profession and the public. The practice of the pharmacologic arts should be under the proper censorship of professional men, who have been educated in our medical and pharmaceutical schools, trained by experts, and licensed to practice after their qualifications have been submitted to and approved by a board of examiners.

Then the practitioners of these arts should be held strictly accountable to laws intended for the protection of the public from ignorance, incompetence, and greed. These laws should include pure food and drug laws, medical and pharmacal laws, and ethical codes, harmoniously blended in such manner as to protect the welfare of the community. And the copyright, patent, and trade-mark laws to be of service in this connection, should be in harmony with the general plan.

As now administered, the patent and trade-mark laws are used by the nostrum trade to protect its nefarious business. This trade twists, contorts, and stretches the patent and trade-mark laws to hide its Satanic character. It fools its victims by false promises and fraudulent claims, and those engaged in the business not only deceive the medical profession and the public, but they actually fool themselves by their own sophistries, until they half believe their own lies and begin to imagine that they are really telling the truth.

This nostrum trade has been well characterized by "Collier's Weekly" as the "Great American Fraud." The nostrum system in all its branches is a system of fraud, error, humbug and lies, whether carried on by the great manufacturing houses or by the retail druggists. The great nostrum manufacturing houses use their advertising patronage to debauch the press, medical, pharmaceutical, secular and religious, and the demand created by this advertising forces the retailers to carry nostrums in stock or to go out of business.

The retail druggists therefore attempt to fight the devil with fire, by supplying to the public nostrums of their own manufacture, in place of those advertised. But this attempt never has been and never can be successful in suppressing the nostrum trade, whether carried on individually or by great organizations of retail druggists under the guise of so-called co-operative manufacturing of household remedies.

This method of doing business cannot be classed as honest professional pharmacy. What the people have a right to demand in exchange for licenses to practice medicine and pharmacy is honest professional service from physicians, pharmacists and manufacturers of medicine. They have
a right to demand that every materia medica product shall have a name of its own by which it can be identified and dealt in. They have a right to demand that such names shall be common property and free to all who have the right to practice the pharmacal arts. They have a right to demand that each product shall be submitted to impartial investigation by the co-operative researches of competent observers; that the medical press shall be thrown open to free discussion of its properties and uses; that the source, composition, methods of preparation, physiological properties and therapeutic application, shall be submitted to such discussion without fear or favor; that the practice of the arts of selecting, preparing, preserving, compounding and dispensing materia medica products shall be conducted by educated and licensed practitioners; that the application of medicines shall be under professional control, and that they shall be used in a proper manner for the treatment of disease by those who are learned in medicine, including pathology and diagnosis; that the knowledge thus evolved by this professional service shall be reduced to law and embodied in system, and shall be taught to the professions by means of the educational machinery adapted to that end; namely, medical and pharmaceutical colleges, societies and press.

The patent and trade-mark laws should be administered by the courts in harmony with these requirements, if their objects are to be attained.

The Chair called for action on the paper just read, which he commended very highly. He said it was a paper that should be read to be appreciated, and was one that could be perused after publication of the Proceedings with interest and profit. It was a paper that called for some expression by this Section upon the subject-matter it represented, and he said he would ask Mr. Stewart, therefore, to present some resolutions which he had embodying this idea.

Thereupon, Mr. Stewart read the following:

WHEREAS, The object of the patent law is to promote progress in science and useful arts, and

WHEREAS, Progress in the science of materia medica and in the arts of pharmacology and therapeutics, upon which it is dependent, requires that each materia medica product and preparation shall have a name of its own, which is free to science and commerce, whereby it may be identified, impartially discussed in the professional societies and press, and thus prepared for a place in the U. S. Pharmacopoeia, and

WHEREAS, The practitioners of the pharmacologic arts, namely, pharmacists, chemists and manufacturers, are dependent upon materia medica commerce for a livelihood, and

WHEREAS, Commerce in materia medica requires the investment of capital and the protection of the same by the legitimate use of patents for new materia medica inventions, and trade-marks for distinguishing between brands, therefore be it

Resolved, That the Report on Patents and Trade-marks of the American Pharmaceutical Association, together with papers and discussions dealing in an explanatory way with the same subject, be referred to the manufacturing houses, with the request that they shall co-operate with the American Pharmaceutical Association in solving the several important problems presented by said report, and that the Committee on Patents and Trade-
marks be empowered to take such action and report the results of the conference at the next meeting of the American Pharmaceutical Association.

The Chair called for action on the paper and resolutions as read, and on motion of Mr. Burge the same were adopted.

The next paper called for was one by E. Fullerton Cook, of Philadelphia, on the subject of a commercial training for pharmacists.

Mr. Cook presented his subject as follows; exhibiting in connection with his text, as illustrative of his methods, various samples of blank-books, registers and forms, actually used by his students, and explained their good points:

TEACHING BUSINESS METHODS TO THE PHARMACIST.

BY E. FULLERTON COOK, P. D.

It is no longer necessary to defend a position which advocates and insists upon a thorough course in business training for the man or woman entering pharmacy. The tremendous advances, as business men, which pharmacists have made during the last ten years, is amazing, and we face today a condition wherein there must be adopted a system of financing, managing, purchasing and selling, as applied to the retail pharmacy, equal in efficiency and economy to the best. The continuance of business life itself is dependent upon the pharmacist taking such a position. Competition is constantly growing more keen; various commercial organizations among druggists are offering better buying methods; the journals are filled with plans for combinations; chain-store schemes, buying clubs, better management, advertising, salesmanship, etc., etc., but the retail pharmacist who has individuality and true professional skill, and combines that with sane and modern business methods, has little to fear from a purely commercial competition and it is with this conception of a pharmacist that emphasis is being laid upon business training as of equal importance with the scientific.

The purpose here is to outline what it is believed such a course should embrace and to illustrate with practical methods of teaching. It would be impossible in a paper of this scope to outline every step which must be covered in the instruction. The details are numerous and cover a large field, and, for the reason that it is specialized, the many phases of business activity which the pharmacist is called upon to enter must be enlarged upon. The following suggestions have been used during the past year and represent the development after nine years of teaching these subjects. Starting some years ago with a course in double-entry book-keeping, as taught in commercial colleges, it was soon recognized that the time spent upon so elaborate a system was useless, as no retail druggist would keep a set of double-entry books unless his business was large enough to warrant the employment of a book-keeper.
Gradually, therefore, the methods have been evolved, constantly striving for simplicity, efficiency and practicability. At the beginning of the course, the student is asked to put himself in a position where he must face the questions that arise on entering business, i.e., into his hands are placed the facts concerning the purchase of a retail drug store, he being one of the parties to the transaction.

This opens for discussion the many factors which should be considered at such a time. The following questions are taken up:

1. Has the training and experience been sufficient to insure success?
2. Would it not be better to become a manager until better experienced?
3. What is the amount of available capital?
   a. Possible sources of capital.
   b. Value of character.
   c. Proven ability to save money.
   d. Life-insurance policy as an asset.
4. Is a partnership preferable to an independent ownership?
   a. Partnership.
   b. Corporation.
   c. Limited partnership.

If the conditions justify the buying of a store, the next questions considered are:

1. Is it desirable to secure an established business?
   A. If unacquainted with the store, investigate:
      a. Neighborhood.
      b. Former reputation of the store.
      c. Amount of bona fide business for preceding year.
      d. Inventory of stock, with unbiased valuation.
      e. Depreciation in fixtures.
      f. Terms of the lease. (A long term usually desirable.)
      g. Unpaid accounts.
   B. Is it desirable to succeed to the business of a former employer? (Although the points given in A must also be fully considered under these conditions, which have long been believed to be ideal, yet they usually answer themselves by the situation in which the man finds himself.)

2. Should a new business be established? If so there should be a careful investigation of the following:
   A. The character of the neighborhood.
   B. Terms of lease as to
      a. Rent.
      b. Time to run, etc.
   C. Purchase of fixtures.
   D. Purchase of stock.
   E. Advertising new business, etc.

It having been decided to go into business, there is next taken up

1. How shall the payments be made?
   a. Proportion of cash.
   b. Promissory notes; their character and significance.
2. Relations with a bank.
   A. Shall it be a national bank or trust company?
   B. Opening an account.
      a. Signature.
      b. Depositing of cash and checks.
      c. Stopping payment on checks.
      d. Overdrawing accounts.
   C. Check-book.
      a. Drawing checks.
      b. Keeping balance.
      b. Paid checks returned.
   E. Use of drafts.
3. Fire insurance.
   a. Insure full value.
   b. Have inventory.
   c. Reliable company.
4. Credit.
   a. Mercantile agencies.
   b. With wholesale houses.
   c. With banks.
5. Clerks.
6. Personal salary.
   This should be included among the regular expenses of the business and should be drawn systematically; the amount depending upon the condition of the business.
7. Letter writing.
8. Mercantile license.
9. Internal revenue license.
10. Credit Customers.
    a. Advantages.
    b. Caution in allowing credit.
    c. Regularity in rendering bills.
    d. Collections.
11. Purchasing supplies.
    c. Order blanks.
    d. Price lists.
    e. Quantity of discounts.
    f. Value of giving attention to salesmen.
12. Paying bills.
    A. Ten-day discount.
       a. Good credit.
       b. Best prices.
       c. Independence.
       d. Money saved.
    B. Borrowing from bank if necessary.

After considering these points the supposition is that the student has begun business, and the transactions for each day for a month are out-
lined and then actually carried out. These include the opening of a bank account, the drawing of a lease, payment for the store in cash and notes, (the student making out the promissory notes) the employment of clerks and porter, payment of rent, mercantile license and internal revenue tax, by checks, the ordering of supplies from a number of different classes of dealers, the writing of letters to secure credit, to make corrections in bill, etc., depositing in bank, of money received from the sales, the payment of petty expenses, opening accounts and charging goods to customers, discounting and payment of bills, the use of day-book, cash-book, check-book, and ledger, and the making-out of bills for customers. These transactions are made to resemble as nearly as possible the conditions of business, and the book-keeping, up to this point, is done exclusively by single entry. As the larger percent of the book-keeping of an average retail drug store will consist of the work already given, and as it can be satisfactorily handled by single-entry, emphasis is laid on this part of the work to insure efficiency in what will perhaps represent 98 per cent. of the book-keeping required.

This portion of the work having been concluded, there follows the question of gross profit, net profit and resources and liabilities. For the few accounts which now are considered, a double-entry system is taught. Total amounts, for the period covered, such as all money due from, and also paid by, credit customers, all money received from cash sales, and all money paid out, are posted in the proper accounts in the ledgers. (All expenses should be carefully assembled; such as personal salary, rental, depreciation on goods, fixtures and building—if owned—all losses, as breakage or uncollectable accounts, salaries, light, heat, insurance, etc.)

An inventory must be taken and this credited to the several accounts. Now a statement showing all profits and all expenses is made, thereby determining the net profit or loss, as the case may be, for the time covered. Usually a statement is taken from the double-entry ledger showing all resources and all liabilities.

Having completed a systematic method for the keeping of accounts, many of the modified forms are illustrated, and their value and application explained; such form as card-index ledgers, loose-leaf ledgers, the bill form of ledger, with carbon duplicate, Wray's Ledger, the Caskey scheme, the cash-register plan, Moore's systems, loose-slip account, etc., etc.

Following the book-keeping, lectures are given on general subjects as insurance, legal papers, letter-writing, ordering goods, banking, business law, notes, drafts, transportation, advertising, State Pharmacy Laws, National Pure Food and Drug Laws, etc.

I may say that twenty or more years ago, Prof. Remington began giving the students several lectures each year in the College of Pharmacy on the subject of business and from this, largely through his stimulation, has been developed the present more elaborate course, given in our insti-
tution, the latter lectures of which are, today, given by him, greatly to the edification and advantage of the student body.

The Chair called for action on this paper, which he said embodied a great deal of labor, time and consideration.

Mr. Mayo moved a vote of thanks to Mr. Cook for his excellent paper. He expressed the opinion that if the Association had more of this kind of work, and more details of this sort, it would contribute substantially to an increase of membership. He said Mr. Cook has given the membership something that would appeal to the practical aspects of the retail drug business. He only wished that he had divided this paper into a half a dozen parts, and given the Association half a dozen papers on the subject. He expressed the hope that he would come back next year and give the Association something else along this line. He regarded this as one of the most valuable papers that had ever been presented before the Association, and believed such contributions should be heartily commended, as it was of vital importance to the Association to have papers dealing with practical subjects in this way.

Mr. Apple endorsed the remarks of Mr. Mayo in regard to the value of the paper last presented, and thought it was desirable to have full discussion on this topic. He said he wanted to make a plea now that the Chairman-elect of the Section on Commercial Interests for next year be given an opportunity to have a symposium on this and like subjects, by the reference of such matter, or part of it, to that Section. He thought, while educational, it was educational in a commercial way, and properly belonged to the commercial section. He believed such a symposium would be edifying and profitable.

The Chair stated he thought the incoming Chairman of the Committee on Education and Legislation would allow an elaboration of at least some form of this paper before the Section on Commercial Interests.

The Chair stated that, before adjournment, he would like the Section to take action on three papers on the program for this session, the authors of which were not present. One, he said, was on Doses in the U. S. Pharmacopœia, by C. B. Lowe, one on "Who owns the Prescriptions?" by J. Winchell Forbes, and the Third on "Teaching Bacteriology in Colleges of Pharmacy", by Albert Schneider, of San Francisco. These three papers, he said, were in the Chairman's hands.

Mr. Meissner moved that the papers referred to be received and referred to the Publication Committee, and this motion was seconded by Mr. Ladish and carried.

The Chair announced a joint session of this Section to-morrow morning, at 10 o'clock sharp, with the National Association of Boards of Pharmacy and the American Conference of Pharmaceutical Faculties, at which time the three remaining papers upon the program for this session would be read and a symposium had upon the subject of examination questions.

On motion, the Section then adjourned.
DOSES IN THE UNITED STATES PHARMACOPEIA.

BY CLEMENT B. LOWE.

It was considered wise by the committee in charge of the Eighth Revision of the United States Pharmacopeia to include in this work the dose of many of the articles and preparations contained therein, the object of doing so being probably to make the book more attractive and helpful to both physician and pharmacist; and it seems that to some extent this result has been achieved. It might be thought on first reflection that the stating of a definite dose would be attractive to students as giving them an exact dose to remember, but this is not so; a student who is asked in examination to state the dose of a drug must at present give the exact amount as stated in the U. S. P.; there is no leeway; he cannot as formerly say that the dose is from so and so to so and so.

It seems to the writer that it would have been of greater value to have given minimum and maximum doses and also the maximum dose for twenty-four hours, as is done in a number of European pharmacopoeias. The latter is specially important and would be of great help in prescription compounding, as it can hardly be expected that the majority of pharmacists are posted in regard to the time of the elimination of drugs from the human system, and yet this largely governs the amount that can be safely taken in twenty-four hours. For instance, hydrocyanic acid is eliminated so rapidly from the system that there would be little danger in taking a maximum dose every hour; on the other hand, potassium bromide is eliminated from the body very slowly; indeed, when administered day after day it tends to accumulate in the body, producing untoward effects. Belladonna, a poisonous drug, rarely produces fatal results, owing to the fact that it is eliminated so rapidly from the system; on the other hand, digitalis is so slowly excreted that it is a question whether more than two maximum doses should be given in twenty-four hours.

It would be a matter of some interest to know just what the sub-committee on doses had in mind when they introduced into the U. S. P. what are called average doses. Did they mean a dose midway between minimum and maximum, or the dose such as is ordinarily given? If the latter was the guiding rule, then certain doses of the U. S. P. are incorrectly stated.

Let us take up in the first place doses of some of the more active drugs, for instance that of morphine, which is stated as one-fourth of a grain, which any good prescriptionist knows is greater than the dose ordinarily prescribed; however, if this is to be taken as correct, then the dose of opium is too small and should have been two grains, as one grain of opium is considered to be equivalent in strength to one-eighth of a grain of morphine sulphate. The dose of tincture of opium is also too small and should have been, to correspond, about twenty minims. It may be answered to this criticism of the dose of opium, that in this drug we have other alka-
loids besides morphine which should be taken into account, but it must be remembered that the action of opium is largely that of morphine, which is its most active alkaloid and which is also present in larger amounts than any other; the only other alkaloid approaching it in amount is narcotine, or as some prefer to call it anarcotine, which does not add to the narcotic effects of opium, but rather antagonizes them, as it is a tetanizing alkaloid. The dose of strychnine, $\frac{1}{4}$ of a grain, seems small; thirty years ago it probably would have been an average dose, but within recent years much larger doses have been given, $\frac{1}{30}$ of a grain being prescribed oftener than any other dose. The dose of atropine sulphate, $\frac{1}{160}$ of a grain, seems small when we learn from the National Dispensatory that the dose is from the $\frac{1}{150}$ to the $\frac{1}{60}$ of a grain, but as much as $\frac{1}{20}$ of a grain is sometimes employed. The dose of corrosive sublimate, $\frac{1}{100}$ of a grain, seems rather large and might produce some colicky pains. Codeine, which has probably less than one-fourth the strength of morphine, is given in $\frac{1}{2}$-grain doses, or only twice the strength of morphine. The dose of phosphorus is given as the $\frac{1}{125}$ of a grain, and yet in the official phosphorus pills the dose is $\frac{1}{100}$ of a grain. Why this difference? Blue pill, which our grandfathers esteemed so highly as a cholagogue cathartic, has been cut from 10 to 4 grains, the latter being less than the dose that is ordinarily taken. Hydrated chloral and potassium bromide are both given in 15-grain doses. This seems strange when we remember that there are cases on record of death from 10 grains of chloral, while on the other hand potassium bromide is a comparatively safe drug, which, according to Prof. Hare, may be taken in doses of 5 to 60 grains. The dose of acетаниліде, 4 grains, has been somewhat sharply criticised. This is probably safe for a single dose, but would be distinctly dangerous if repeated often. The writer well remembers the cyanosis produced in a patient some twenty years ago (at that time the drug was used as an antipyretic), two five-grain doses being given at an interval of some hours. The lesson then learned has lasted to this day. Antipyrin is also given in four-grain doses, although it is a much safer drug than the former. * It is asserted in the N. D. that "as much as 20 grains may be given without detriment." By comparison the first of these seems too large, the second too small, the dose of acetphenetidin, $7\frac{1}{2}$ grains, seems nearer the correct mark. The dose of cerium oxalate, 1 grain, seems small when we learn from the N. D. that the drug is given in from 2- to 10-grain doses. I have myself known of 30 grains being given without injurious effects, but would not sanction the giving of such large doses. The dose of bismuth subnitrate, $7\frac{1}{2}$ grains, seems small when we learn from the N. D. that the drug is given in doses of from 16 to 60 grains. The dose of cocaine hydrochloride seems a little large when we remember the untoward effects sometimes produced by no larger doses. There seems to be a discrepancy between the doses of nutgalls and tannic acid, both being given in doses of $7\frac{1}{2}$ grains, when
the former contains from 50 to 60 per cent. of the latter. The dose of potassium cyanide is given as \( \frac{1}{3} \) of a grain; according to the N. D. it is \( \frac{1}{12} \) to \( \frac{1}{6} \). The dose of gold and sodium chloride, \( \frac{1}{10} \) of a grain, also seems large; the N. D. gives it as \( \frac{1}{20} \) of a grain. The dose of aromatic powder, 15 grains, while not actually injurious, seems large; it would certainly act as a warm stimulant in the stomach. When compounding powders for the medication of an infant, containing one grain each of aromatic powder, I have tasted the powder and wondered whether the effect would be beneficial to the delicate mucous membrane of the infant's stomach. The dose of sodium phosphate, 30 grains, seems small when we learn from the N. D. that as a laxative it is used in 30- to 120-grain doses and as a purgative in from 1 to 2 ounces.

The dose of chlorinated lime is given as 4 grains. The N. D. gives it as 1 to 5 grains, but it is so seldom used internally that there was little necessity of stating it. The official dose of castor oil is given as half an ounce, but this is only half the size of the dose usually demanded by people when dispensed in the pharmacy. The volatile oils seem to a large extent to have been lumped together; they are given in three-minim doses, the list consisting of the following oils, viz.: Anise, caraway, chenopodium, coriander, fennel, juniper, lavender, nutmeg, pennyroyal, pimenta, peppermint, rosemary, spearmint and thyme. The N. D. gives the average dose of oil of thyme as 2 minims and that of a number of others in the list as much larger. Oil of turpentine, according to the U. S. P., is given in 15-minim doses, which seems rather large in view of the fact that the drug is an active stimulating diuretic. It will be noticed that we have compared the doses given in the U. S. P. with those given in the National Dispensatory for the reason that the medical author of the latter book was also the chairman of the committee having in charge the matter of doses in the U. S. P.

What has been written in this brief paper upon doses has not been for purposes of carping criticism, but for the purpose of promoting constructive metabolism in this great work, of which the medical and pharmaceutical professions are justly proud.

WHO OWNS THE PRESCRIPTION?

J. WINCHELL FORBES.

In construing contracts by courts of justice, the first point considered is in all cases the intention of the parties to the contract, and it is often the case that an implication, if perfectly clear, and one which the verbiage and general construction leads to naturally, may be of greater importance than the meaning of the simple verbiage.

The transaction which takes place between a man who visits a physician, seeking treatment for some ailment, and the physician, is in the nature of a contract; and the inevitable complaint that the one treated makes, if the
treatment is ineffectual, is an indubitable proof that the treated one so considers it. That the physician himself so considers it, or at least knows that his patient does, is proved by the fact that a favorite advertising device is: "No cure, no pay," for the physician, and for the patient the expression: "I paid him my good money and he didn't do me any good." It may be considered, therefore, that the transaction between the physician, and the man or woman who requests his services, is in the nature of a contract. The intention and expectation on the part of the patient, whether he parts with his money in a single lump, or in instalments, is that he will receive certain benefits, and the physician well knows that such is the case.

The physician examines the patient, notes the symptom, and makes his diagnosis. Now, does he say to the patient, for example: "The ventricular diastole is not properly balanced with the systole, and there is a decided pathological action of the cardiac impulse—you are threatened with ingrowing toenail on the umbilicus" (and one of these two pronouncements is about as lucid as the other so far as comprehension by the patient is concerned), or does the doctor even try to translate the technical into the commonplace, and tell the man what ails him, and in non-technical terms? Not a bit of it! If he is a dispensing doctor, so called, he takes his money, gives him a few tablets, and tells him to call for more when those are gone. If he is not, he writes some hieroglyphics on a bit of paper, and tells his patient to go to a drug store with it and have the druggist do what the hieros tell him. The man takes the paper. Is he cured? Have the terms of the contract been complied with? No one would scout such a conclusion more forcibly than the man who holds the prescription in his hand. Presumably, the doctor has diagnosed correctly, and written on the piece of paper instructions for preparing the proper medicine to meet the indications, but for all that, the patient has so far not received any equivalent for his money. The actual treatment has just begun.

He wants to be cured, or at least benefited, and the method of curing is left to the doctor. The only course for the patient to follow is to comply with the directions. In compliance therewith, the man hies him to an apothecary, who translates the hieros, prepares the medicine as directed and hands the result to the patient, who is incontinently rid of his ailment. Not a bit of it!

The actual status of the bit of paper is the same as if it were written in this way: To any apothecary to whom this may be presented. Give or prepare the articles named on this paper, accompanied with direction to use thus and so.

The actual contract between the physician and the patient is, that in consideration of certain money paid to the physician, the patient is to be cured of his ailment.

If it be claimed that the money was paid the physician for the use of his
skill, and that the writing and delivery of the written prescription constitutes such use, it is no cause for complaint on the part of the patient if the medicine he gets from the apothecary does him no good. If he paid for the prescription, he got all that was coming to him. In spite of the loud-mouthed ravings of some, that: "I paid my money for that prescription, and it is mine," it is very doubtful if a single individual of the ravers could be found who would admit that with the writing of the prescription and its delivery to him he got all that was coming to him. He knows better. He had no idea of paying for any of the detailed steps of the doctor's method, but as he understood it, he was paying for the result of the method—a cure. For all he knew, his case demanded a serial course, comprising many prescriptions and various medicines, one being preparatory for others; and the prescription written first might be proper for Monday but highly improper for the following Saturday. With a conscientious doctor, each prescription is always written from the standpoint of meeting certain present conditions, hence a renewal of a prescription, except upon the direction of the physician writing it, is an unthinkable thing. The use of the prescription for the benefit of any other person is still more unthinkable.

The written prescription may, or may not, be one of a series, and the decision rests not with the patient, but solely with the writer; and it must be distinctly understood that it is not the business of a physician to sell formulas for curing certain diseases, for such things as specific cures for certain named diseases are unknown to medicine. The terms of the implied contract between a physician and his patient warrant no such conclusion. All that the terms imply are that a cure or alleviation of the ailment is to be the result of the treatment, the steps of the treatment resting wholly with the physician, the only province of the patient being the strict following of the steps.

Assuming that after the patient's faithful following of the first step, which manifestly consists in presenting the first prescription to an apothecary, who presumably follows its direction, the sub step, which is taking the medicine according to directions, is taken by the patient, yet no relief is experienced. What then?

The patient goes again to the physician and says: "That prescription did me no good." What happens? Does the doctor reply: "That prescription was the correct one for a man in your condition, and if it did you no good that is your own fault and not mine?" No. He asks some more questions, and either tells him to have the prescription renewed or he may write another and a different one. Is the man cured then? Hardly. It may happen that this occurs many times. The physician may write ten different prescriptions, and the patient may dose himself with that number of different medical simples or combinations and at the end be no better off than at first. Does the patient consider the terms of the contract as complied with? Not one time.
He complains. He may say: "I paid the doctor for ten prescriptions and I'm no better; I paid that doctor twenty dollars for advice and he did me no good; I paid that doctor twenty dollars for the use of his medical knowledge and skill and I am just as bad as I ever was." Or he may say: "I spent twenty dollars with that doctor but I am no better." In my own experience I knew one M. D. who admitted that he charged for his prescriptions, and N. A. R. D. Notes gives another instance. A doctor who will admit that is placed in a peculiar position. I quote from an address delivered by Dr. J. N. Hurty, of Indianapolis Ind.

"I do not mean to say that medicines are useless, but I do say that they cannot and do not cure disease. The old notion that nature has provided a medicine for the cure of every disease is not now advanced, except perhaps among the Indians, the quacks and the ignorant."

This is the essence of modern medical belief, and the doctor who sells his prescription (a proceeding which is neither more nor less than furnishing the formula for a medicine which will cure a certain disease) is a fraud and a cheat, and he comes within Dr. Hurty's list. He is either an "Indian" or a "quack," and he certainly is "ignorant."

The instance given by Notes is interesting. A woman got a prescription from a New York specialist. She had it filled in New Jersey. In course of time she needed more of the medicine and asked the druggist for a refill. Now, the medicine contained cocaine, and the New Jersey law prohibits the refilling of such prescriptions. She demanded the original prescription. The druggist refused to give either that or a copy, and the woman complained to the writer of the prescription, who gave her a note to the druggist requesting him to refill. The druggist still refused, and the doctor wrote him quite a long, berating letter, in which he said that the woman had paid him for the prescription and it was hers. The original prescription contained about fifteen words, and his order to refill and the berating letter about four hundred, yet the whole matter could have been settled amicably by the writing of another prescription of fifteen words; the woman would have been able to get her medicine at once, and the druggist would not have been asked to break the law. This was a case of either the most crass stupidity or one of egoistic obstinacy on the part of the doctor, and either one shows that that particular doctor did not possess the first essential for the practice of medicine, and that his proper sphere was manual labor at the rock pile, carrying the hod or something of that nature which involves no action of the brain.

But to resume. If the patient paid for the prescriptions, he got them. If he paid for advice, he got it. If he paid for the use of medical knowledge and skill, he got it.

But when he says that he "spent twenty dollars with that doctor, and I am no better," he states unmistakably his understanding of the contract, and the fact that he complains shows that that is what he means by every
